INTRODUCTION	xv
--------------	----

BOOK I

CHAPTER 1

1.0	PRE-COLONIAL SUB-SAHARAN AFRICAN CIVILIZATIONS AND CO-EVOLUTION WITH WILDLIFE	1
1.1	PRE-HISTORIC AFRICA – THE CRADLE OF MANKIND	3
1.2	MAN THE HUNTER	24
1.3	CO-EVOLUTION OF HUMANS AND WILDLIFE IN SUB-SAHARAN AFRICA	29
1.4	WEST AFRICAN KINGDOMS AND EMPIRES	37
1.5	HORN OF AFRICA - ANCIENT ABYSSINIA (MODERN ETHIOPIA)	79
1.6	EASTERN SUDAN (MODERN-DAY SUDAN)	84
1.7	BANTU AFRICA	90
1.8	CONCLUSIONS	124

CHAPTER 2

2.0	TRADITIONAL NATURAL RESOURCE MANAGEMENT IN SUB-SAHARAN AFRICA	135
2.1	TRADITIONAL HUNTING AND WILDLIFE MANAGEMENT	139
2.2	TRADITIONAL FISHERIES MANAGEMENT	198
2.3	TRADITIONAL MANAGEMENT OF LAND, AGRICULTURAL AND PASTURE	205
2.4	TRADITIONAL FORESTRY MANAGEMENT	229
2.5	CONCLUSIONS	230

CHAPTER 3

3.0	COLONIALISM AND THE IMPOSITION OF WESTERN WILDLIFE MANAGEMENT SYSTEMS	249
3.1	COLONIAL STATE IN AFRICA	249
3.2	WILDLIFE AS A TOOL OF CONQUEST, PLUNDERING AFRICA'S WILDLIFE RESOURCES BY EARLY EUROPEAN SETTLERS	285
3.3	PERCEPTION THAT AFRICANS WERE THE CAUSE FOR WILDLIFE DECLINE	292
3.4	DEVELOPMENT OF AN ENVIRONMENTAL CONSCIENCE AND EXCLUSION OF AFRICANS FROM LEGALLY ACCESSING WILDLIFE	295
3.5	DEVELOPMENT OF HUNTING ETHICS IN AFRICA	324
3.6	THE END OF COLONIALISM AND THE ACCELERATION IN PHYSICAL SEPARATION OF AFRICANS FROM THEIR RESOURCES	332

3.7	CREATION OF OPEN ACCESS RESOURCES	344
3.8	LAND COMPRESSION	351
3.9	ECO-GENOCIDE	361
3.10	REMOVAL OF WILDLIFE AS AN IMPORTANT PROTEIN SOURCE IN AFRICAN DIET'S	377
3.11	INCREASING HUMAN POPULATIONS, HABITAT DEGRADATION, HARD-EDGED PARKS AND PROTECTED AREAS	378
3.12	COMPARISON WITH EUROPEAN COLONIZATION OF NORTH AMERICA	385
3.13	CONCLUSIONS	411

CHAPTER 4

4.0	IMPERIALISM, INDEPENDENCE AND FRESHWATER FISHERIES IN SUB-SAHARAN AFRICA	445
4.1	INTRODUCTION	445
4.2	BACKGROUND	449
4.3	INTRODUCTION OF EXOTICS	452
4.4	SPECIES EXTINCTION	454
4.5	EUTROPHICATION	456
4.6	ADAPTATION	459
4.7	CHANGES IN MAKE-UP OF CATCH COMPONENT	459
4.8	FISH YIELDS WITH EXOTICS	460
4.9	SOCIO-ECONOMIC IMPACTS, NEW STAKEHOLDERS	462
4.10	FISHERY MANAGEMENT	470
4.11	THE FUTURE	474

4.12 CONCLUSION	475
-----------------	-----

BOOK II

CHAPTER 5

5.0 AGRICULTURE IN SUB-SAHARAN AFRICA (SSA) SINCE COLONIALIZATION	481
5.1 INTRODUCTION	482
5.2 ECONOMICS OF AGRICULTURE IN AFRICA	483
5.3 FOOD PRODUCTION	486
5.4 HUNGER LINKED TO POVERTY	503
5.5 LAND USE POTENTIAL AND CONSTRAINTS IN SUB-SAHARAN AFRICA	508
5.6 LAND DEGRADATION	522
5.7 POLICY REFORM CONSTRAINTS TO AGRICULTURAL PRODUCTION	570
5.8 HIV/AIDS DECLINING AGRICULTURAL PRODUCTION AND FOOD SECURITY IN SUB-SAHARAN AFRICA	638
5.9 OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY	644
5.10 CIVIL WARS - A MAJOR CAUSE OF DECLINING AGRICULTURAL PRODUCTION AND FAMINE IN SUB-SAHARAN AFRICA	710
5.11 CONFLICT LINKED TO OVER-POPULATION AND DESERTIFICATION – SCARCE RESOURCES	714
5.12 THE WAY FORWARD	736
5.13 CONCLUSIONS	826

CHAPTER 6

6.0	HABITAT DEGRADATION, LINKED TO COLONIAL/POST-COLONIAL POLICIES AND WATERING POINTS/BOREHOLES IN SUB-SAHARAN AFRICA	899
6.1	IMPACTS OF BOREHOLES ON PASTORALISM	902
6.2	BOREHOLES AND WILDLIFE	976
6.3	GUIDELINES FOR WATERING POINTS	984
6.4	CONCLUSION	987

BOOK III

CHAPTER 7

7.0	IMPACTS OF DAMS ON CONSERVATION AND DEVELOPMENT IN SUB-SAHARAN AFRICA	1029
7.1	BIG DAM ERA IN THE WESTERN UNITED STATES	1032
7.2	END OF THE BIG DAM ERA IN THE WEST	1034
7.3	ECONOMIC RETURNS FROM BIG DAMS	1034
7.4	PEOPLE AFFECTED BY DAMS	1034
7.5	FUNDING DAM BUILDING IN AFRICA	1036
7.6	CONTRIBUTION OF DAMS TO FOOD PRODUCTION AND NUTRITION IN AFRICA	1041
7.7	RIVER BASIN PLANNING AND DAMS IN AFRICA	1041
7.8	ENVIRONMENTAL COSTS OF DAMS AND RELATED DEVELOPMENT IN AFRICA	1080
7.9	SOCIO-ECONOMIC IMPACTS OF DAMS IN AFRICA	1193
7.10	PLANNING AND MITIGATION	1251

7.11	ALTERNATIVES TO LARGE DAMS	1284
7.12	CONCLUSION	1287
	CHAPTER 8	
8.0	MINING TROPICAL COASTAL ZONES, LESSONS FROM THE CARIBBEAN, IMPLICATIONS FOR EAST AFRICAN CORAL REEFS	1325
8.1	INTRODUCTION	1326
8.2	GENERAL	1339
8.3	“BOTTOM-UP” VERSUS “TOP-DOWN” THEORIES EXPLAINING DEVELOPMENT OF ALGAL REEFS	1358
8.4	CORAL REEFS UNDER THREAT	1364
8.5	LAND-BASED POLLUTION	1371
8.6	DOMESTIC SEWAGE AS A KEY COMPONENT OF LAND-BASED POLLUTION	1380
8.7	KEY SPECIES OF EPIPHYTIC ALGAE ASSOCIATED WITH LAND-BASED NUTRIENT POLLUTION	1413
8.8	SEDIMENTATION AS A KEY COMPONENT OF LAND-BASED POLLUTION	1415
8.9	IMPACTS OF PESTICIDES AND FERTILIZER FROM LAND-BASED POLLUTION ON CARIBBEAN CORAL REEFS, LESSONS FOR AFRICA	1420
8.10	OTHER CAUSES FOR CORAL REEF DEGRADATION	1422
8.11	COASTAL DEGRADATION EAST AFRICA AND SOUTHWESTERN INDIAN OCEAN	1455
8.12	SUMMARY - PERSONAL OBSERVATIONS OF CORAL REEF DEGRADATION IN AFRICA	1459
8.13	THE FAILURE OF MARINE PARKS IN THE CARIBBEAN TO ADDRESS BIODIVERSITY ISSUES AND THE REAL	

CAUSES OF CORAL REEF DEGRADATION – LESSONS FOR AFRICA	1468
8.14 THE NEED TO WORK WITH FISHER COMMUNITIES TO MANAGE THEIR COASTAL ZONES	1470
8.15 KEY ACTIONS TO MITIGATE THREATS TO CORAL REEFS	1477
8.16 CONCLUSION	1485

BOOK IV

CHAPTER 9

9.0 COMMUNITY-BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS – THE WAY FORWARD FOR SUB-SAHARAN AFRICA?	1515
9.1 THE CULTURAL DIVIDE	1519
9.2 THE CRITICAL LINK, CBNRM AND ADAPTIVE MANAGEMENT IN AFRICA	1524
9.3 COMMUNITY-BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS – PART OF THE WAY FORWARD	1529
9.4 ORIGINS OF CBNRM IN AFRICA	1543
9.5 SUCCESS OF CBNRM BASED ON CONSUMPTION AND COMMODITY PRODUCTION	1554
9.6 EVOLUTION OF CBNRM IN AFRICA	1569
9.7 CBNRM SHORTCOMINGS, STAGE 3 CONSERVATION/ WILDLIFE MANAGEMENT WITH THE PEOPLE	1627
9.8 THE WAY FORWARD – CONSERVATION BY THE PEOPLE – STAGE 4 EQUALS DEVOLUTION	1805
9.9 WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM	1868

9.10	CONCLUSIONS	1889
------	-------------	------

CHAPTER 10

10.0	CITES AND THE ESA, NEO-COLONIAL IMPACTS ON SUB-SAHARAN AFRICAN CONSERVATION	1947
10.1	THE CONVENTION FOR THE PRESERVATION OF ANIMALS, BIRDS AND FISH IN AFRICA	1948
10.2	AFRICAN INDEPENDENCE AND POACHING	1949
10.3	CITES	1952
10.4	THE AFRICAN ELEPHANT	1985
10.5	RHINO, TRADE OR TRADE CONTROL, WHAT'S BEST FOR CONSERVATION?	2017
10.6	CITES RESOLUTION 2.11	2024
10.7	ENDANGERED SPECIES ACT OF THE USA, IMPEDIMENT TO AFRICAN CONSERVATION	2026
10.8	THERE'S AN AFRICAN LION JUST AROUND THE CORNER	2052
10.9	CONCLUSION	2074

BOOK V

CHAPTER 11

11.0	"INDEPENDENCE", "DEMOCRACY" AND FOREIGN AID DEPENDENCY, IMPACTS ON CONSERVATION AND DEVELOPMENT IN SUB-SAHARAN AFRICA	2101
11.1	WINDS OF CHANGE	2102
11.2	END OF COLONIALISM	2103
11.4	ECONOMIC DEVELOPMENT AT INDEPENDENCE	2111

11.5	AFRICA UNRAVELS – STATE LED DEVELOPMENT	2117
11.6	AFRICAN DEMOCRACY IN THE 20 AND 21 ST CENTURIES	2126
11.7	FOREIGN ASSISTANCE IN GENERAL	2181
11.8	FOOD AID	2248
11.9	THE NEW SAVIORS OF SUB-SAHARAN AFRICA; NGOs	2260
11.10	FOREIGN AID AND THE ENVIRONMENT	2264
11.11	CASE STUDIES, USE OF FOREIGN ASSISTANCE TO IMPOSE WESTERN PRESERVATION PHILOSOPHIES ON RURAL AFRICANS	2300
11.12	TRADE NOT AID	2461
11.13	AREAS WHERE FOREIGN AID CAN MAKE A DIFFERENCE – EDUCATION AND HEALTH	2461
11.14	CONCLUSIONS	2488

BOOK VI

CHAPTER 12

12.0	SUBSIDIES, FREE-TRADE, STRUCTURAL ADJUSTMENT AND DEBT RELIEF IN SUB-SAHARAN AFRICA - IMPACTS ON RESOURCE EXPLOITATION	2543
12.1	COMMODITY DEPENDENT, AFRICAN GOVERNMENTS FALL IN-DEBT – SPIDER WEB OF THE WORLD BANK AND IMF	2544
12.2	SUBSIDIES AND FREE-TRADE	2552
12.3	STRUCTURAL ADJUSTMENT, IMF AND THE WORLD BANK	2595
12.4	STRUCTURAL ADJUSTMENT FOOD PRODUCTION AND LAND/RESOURCE DEGRADATION IN SUB-SAHARAN AFRICA	2625

12.5	DEBT AND STRUCTURAL ADJUSTMENT POLICIES	2650
12.6	IMPACTS OF STRUCTURAL ADJUSTMENT ON SOCIAL WELFARE AND EMPLOYMENT	2663
12.7	NET RESULT OF STRUCTURAL ADJUSTMENT ON AFRICA – NEGATIVE	2672
12.8	CORRUPTION AND FAILURE OF IMF/ WORLD BANK PROGRAMS	2687
12.9	THE WAY FORWARD	2692
12.10	CONCLUSION	2701

CHAPTER 13

13.0	THE CURRENT AND FUTURE ROLE OF THE PRIVATE SECTOR IN SUB-SAHARAN AFRICA, RESOURCES WARS OR NEPAD?	2727
13.1	CURRENT STATE OF AFRICAN ECONOMIES	2731
13.2	INSECURITY AMONG THE PRIVATE SECTOR	2740
13.3	CAPITALISM WITHOUT A CONSCIENCE	2742
13.4	EXPROPRIATION OF NATURAL RESOURCES, IMPLICATIONS FOR REGIONAL AND NATIONAL SECURITY	2753
13.5	FAILURE TO DEVELOP GOOD GOVERNANCE IN MINERAL RICH COUNTRIES	2754
13.6	ENVIRONMENTAL STRESS AND POTENTIAL CONFLICTS	2757
13.7	GLOBALIZATION AND MULTI-NATIONALS – CORPORATE CAPITALISM	2765

13.8	FRANCE/U.S. ANGLOPHONE COMPETITION FOR INFLUENCE AND RESOURCES IN AFRICA – NEW SCRAMBLE FOR AFRICA	2784
13.9	GLOBALIZATION, AFRICA AND RESOURCE WARS – CAPITALISM WITHOUT A CONSCIENCE – BOOTY FUTURES	2858
13.10	RESOURCE WARS	2861
13.11	AFRICA'S POTENTIAL WATER WARS	2962
13.12	CAPITALISM WITH A CONSCIENCE	2974
13.13	TRADE NOT AID	2999
13.14	NEPAD	3041
13.15	NEED FOR THE WEST AND WTO TO LOWER TARIFFS, SUBSIDIES AND OTHER PROTECTIVE MEASURES IF NEPAD AND AGOA ARE TO WORK	3046
13.16	NEW MILLENNIUM CHALLENGE ACCOUNT	3046
13.17	INTEGRATION OF SUB-SAHARAN AFRICA INTO THE INFORMATION AGE	3048
13.18	SUB-SAHARAN AFRICA'S FUTURE	3050
13.19	CONCLUSION	3057

BOOK VII

CHAPTER 14

14.0	SUGGESTED ROADMAP FOR THE WAY FORWARD	3107
14.1	INTRODUCTION	3107
14.2	THE WAY FORWARD –A ROADMAP FOR THE FUTURE	3166
14.3	ROLE OF WATCHDOG NGOS	3203
14.4	CONCLUDING REMARKS	3204
	ACRONYMS	3209
	INDEX	3241

LIST OF TABLES

Table 1.1	Examples and origins of early domestic crops from around the ancient world	16
Table 3.1	Dates and estimated numbers on the near extinction of key mega-fauna in Southern Africa	288
Table 3.2	Over-exploitation of wildlife and its habitat in pre-industrialized America and its recovery in the 20 th century from conservation efforts – mainly by hunter-conservationists	395
Table 3.3	The majority of U.S. federal and state lands permit multiple use of resources by citizens	408
Table 4.1	1994 landings and exportation of Nile perch, Lake Victoria	461
Table 5.1	The number of people dieing from famine by region of the world and by decade	486
Table 5.2	Population, per capita dietary energy supply and prevalence of under-nourishment	498
Table 5.3	Daily per capita caloric availability from various scenarios for Sub-Saharan Africa, 1990 and 2020	499
Table 5.4	Estimated food production, demand and imports, Sub-Saharan Africa, 1997 and 2020	501
Table 5.5	An estimate of agricultural land use potential in Sub-Saharan Africa (SSA)	509
Table 5.6	Climate, soil and terrain constraints to rainfed crop production south of the Sahara	511
Table 5.7	Extent and causes of declining soil fertility in Africa	517
Table 5.8	Estimates of all degraded lands (in million km ²) in <u>dry areas</u> from unsustainable agricultural and landuse practices	523

Table 5.9	Land degradation severity by percent severity class	524
Table 5.10	Nutritional value of traditional grains and corn	569
Table 5.11	HIV/AIDS infections in Africa (millions of people)	639
Table 5.12	Existing and projected populations in Africa and Sub-Saharan Africa	646
Table 5.13	Population increases Sub-Saharan Africa by country, 1950-2000	647
Table 5.14	Sustainable human population (no/km ²) in West Africa under the traditional land uses of rainfed cropping, livestock production and natural forest cover	652
Table 5.15	Land degradation severity and population density by region (Population density in number of inhabitants per square kilometer (km ²))	653
Table 5.16	Global trends in agricultural productivity and fertilizer use, 1979-1995	655
Table 5.17	Actual land use. Arable land and permanent crops in Africa and Sub-Saharan Africa	655
Table 5.18	Countries in Sub-Saharan Africa with significant amounts of remaining high-potential arable land, 1994	659
Table 5.19	Changes in vegetation types over time, The Gambia	671
Table 5.20	Sub-Saharan Africa forest cover in 2000	682
Table 5.21	Forest and woodland cover in Africa and Sub-Saharan Africa 1961-1994	683
Table 5.22	Forest cover loss in Africa, 1980-90	685
Table 5.23	Some estimates of the main causes of deforestation (percent of total deforestation)	689
Table 5.24	Sub-Saharan African countries facing food emergencies at the beginning of the 21 st century	711

Table 5.25	Estimates of African land area belonging to vulnerability classes and corresponding number of impacted population	717
Table 5.26	Agricultural development/food strategies	739
Table 5.27	Pros and cons of different techniques used in organic matter management	749
Table 5.28	Actual irrigation in Africa and Sub-Saharan Africa	769
Table 5.29	Environmental impact assessment of irrigation, by basin in Africa	770
Table 5.30	Water productivity gains when shifting from conventional surface irrigation to drip irrigation	785
Table 5.31	Road infrastructure in Africa compared to other developing regions	793
Table 5.32	Annual growth in world animal protein production by source, 1990-2002	818
Table 6.1	Land area in Africa by aridity zone (millions of km ²)	900
Table 6.2	Livestock numbers Sub-Saharan Africa, 1961-2003	959
Table 6.3	Comparison between the " <i>conventional</i> " colonialism/independence and the " <i>opportunistic</i> " approaches to pastoral tenure in dryland Africa	963
Table 6.4	Decline of roan antelope, Kruger National Park	979
Table 7.1	Economic benefits from annual flooding of the Waza-Logone Floodplain	1088
Table 7.2	Groundwater quality data for irrigation potential, Gambia River Basin	1091
Table 7.3	Projected fish yields (Kg/Ha/Yr) from proposed reservoirs on the Gambia River	1097

Table 7.4	Projected fish yields from key reservoirs using the morpho-edaphic Index (MEI)	1098
Table 7.5	Annual fish harvests in the Senegal River Basin before and projected harvests after various levels of proposed development, assuming annual average flood	1108
Table 7.6	Projected fish harvests based upon review of literature after construction of the Manantali and Diama Dams, Senegal River	1110
Table 7.7	ORSTOM biologists' projections of fish losses if inundation of Yaéres Floodplain ceased as result of SEMRY rice scheme	1117
Table 7.8	Summary of fish and shellfish of the Gambia River whose life cycles are tied to estuarine mangrove ecosystems	1129
Table 7.9	Known ties of commercially important <u>finfish</u> species to the Gambia River Estuary	1130
Table 7.10	Known ties of commercially important shellfish species to the Gambia River Estuary	1131
Table 7.11	Annual fish catches in metric tons by species, Department Of Kaolack, 1972-1984	1140
Table 7.12	Relative abundance of fish species related to salinity, Casamance, Senegal	1142
Table 7.13	Annual catch records of sole from the Casamance	1147
Table 7.14	Wildlife population reduction between 1968 and 1990 Zambezi Delta complex	1177
Table 7.15	Decline of Kafue Lechwe population over time	1180
Table 7.16	Major dams in Africa that have affected local communities	1194
Table 7.17	Number of women who would lose their tidal rice fields as a result of the Balingho barrage	1199

Table 7.18	Agricultural lands and villages inundated by proposed high dams on the Gambia River	1200
Table 7.19	Economic losses from reduced annual flooding of the Waza-Logone Floodplain as a result of the SEMRY Scheme/Maga Dam	1206
Table 7.20	Projected rice yields in the estuary and Lower Freshwater River Zone with high dam options only (no Balingho Barrage), Gambia River	1220
Table 7.21	Summary of projected, available amounts of nutrition from agricultural products on an annual basis with implementation of the proposed plans of development in the Senegal River Basin	1238
Table 7.22	Summary of projected, available caloric and protein intakes for the population of the Senegal River Basin on an annual basis with implementation of the proposed plans for development	1241
Table 7.23	Projected loss of annual rice yield potential in the estuary and Lower Freshwater River Zone with Balingho Barrage	1245
Table 7.24	Old and new concepts for river basin planning and dam placement	1255
Table 7.25	Net benefits from pilot artificial flooding of Waza Logone floodplains	1277
Table 7.26	Re-inundation options, Waza Logone floodplain	1278
Table 7.27	Estimated cost and benefits for various options for artificial flooding of Waza Logone Floodplain	1278
Table 8.1	Background concentration in unpolluted Eastern Caribbean Waters	1353
Table 8.2	Recommended ambient nutrient water quality standards in nearshore waters, not to be exceeded “Threshold Concentrations” to protect coral reefs from overgrowth of epiphytic algae	1354

Table 8.3	Summary of the current status of coral reefs in the 17 regions of the world designated as nodes within the Global Coral Reef Monitoring Network (GCRMN)	1366
Table 8.4	Comparison of pollution removal by wastewater treatment and disposal options	1384
Table 8.5	Comparison of sewage treatment levels proposed for Grand Anse Beach, Grenada	1385
Table 8.6	Typical sewage treatment systems and impacts on coral reefs observed by author in the Caribbean (1989-1990)	1391
Table 8.7	Overview of domestic wastewater systems in selected Caribbean countries, 2002	1398
Table 8.8	Pesticide use in the Caribbean, 1988/89	1421
Table 8.9	Percent coral cover during 1997/98 (pre-bleaching), 1999 and 2001/02 at monitoring sites in East Africa	1430
Table 8.10	Percent coral reefs at risk from human activities along East African coast, current and future	1432
Table 8.11	Average global climate change projections	1437
Table 8.12	Underwater survey observation, Mahé and St Anne marine park, the Seychelles	1461
Table 8.13	Other personal observations of principal author off African coast	1466
Table 8.14	Key actions to coral reef protection	1478
Table 9.1	CBNRM tends to be driven by market forces for wildlife	1555
Table 9.2	CAMPFIRE income (\$US) , 1989-1999	1556
Table 9.3	Elephant declines, Luangwa Valley	1574

Table 9.4	Prime hunting blocks, Zambia in 1995	1576
Table 9.5	Changes in wildlife numbers of key species contributing to biomass, Queen Elizabeth National Park, 1969-1992	1624
Table 9.6	Links between different tenurial arrangements and potential for community conservation	1643
Table 9.7	Household level income from various CBNRM programs in the 1990s and early 2000s	1692
Table 9.8	Gross household benefits, CAMPFIRE, Zimbabwe (US\$)	1699
Table 9.9	Luangwa Valley game management areas (GMAs) 1991 revenue retained by communities from concession fees – ADMADE program	1706
Table 9.10	Summary of client perceptions from confidential questionnaire by 71 overseas hunters in ADMADE communal areas in 1998	1707
Table 9.11	Income earned by Nyae Nyae conservancy and members, 1997-2002, Namibian dollars/US dollars	1716
Table 9.12	Distribution of income from safari hunting with outside safari company managing hunting block	1729
Table 9.13	Distribution of income from safari hunting with Community owned safari company and trophy fees going to land owner	1736
Table 9.14	Chasse libre costs Burkina Faso, direct costs going to community and government	1739
Table 9.15	Burkina Faso <i>chasse libre</i> costs to hunter other than direct safari costs	1741
Table 9.16	Growth in hunting companies, Tanzania	1765

Table 9.17	Subdivision of Wengert-Windrose Northern Maasailand hunting blocks, from 2 to 5 early 1990s and multiplication of safari hunting quotas without biological data	1768
Table 9.18	Conditions in Sub-Saharan Africa supporting the development of CBNRM	1797
Table 9.19	Estimation of the big mammal populations, Comoé-Léraba Reserve between 1997 and 1999	1848
Table 9.20	Proposed WMAT 2003-2004 tribal member hunting quotas	1881
Table 10.1	African elephant populations early 1900s	1948
Table 10.2	Decline of key mega-fauna from poaching Central African Republic (CAR/RCA)	1965
Table 10.3	Estimates of bushmeat consumption in Equatorial Africa	1974
Table 10.4	Comparison of bushmeat prices/kg to alternative sources of protein, Southeastern Cameroon	1983
Table 10.5	Elephant populations Southern Africa, doubling every 10-15 Years	1997
Table 10.6	Elephant population growth, Hwange National Park, Zimbabwe, 1900-2000	2004
Table 10.7	Export of elephant parts, 1998-2004, Botswana	2010
Table 10.8	Export of elephant parts, 1998-2004, Namibia	2011
Table 10.9	Export of elephant parts, 1998-2004, South Africa	2012
Table 10.10	Export of elephant parts, 1998-2004, Zimbabwe	2013
Table 10.11	White rhino (<i>Ceratotherium simum</i>) population recovery – South Africa	2018

Table 10.12	Decline in black rhino (<i>Diceros bicornis</i>) populations, Sub-Saharan Africa	2019
Table 10.13	Cheetah populations, Namibia	2029
Table 10.14	Export of lion hunting trophies from Africa, 1992-2002	2057
Table 10.15	Export of lion skins from Africa, 1992-2002	2058
Table 10.16	Comparison of African lion population estimates by two recent surveys	2063
Table 11.1	Democratic status of Sub-Saharan countries, December 1999	2127
Table 11.2	2006 Corruption Perception Index (CPI)	2144
Table 11.3	Percentage of total net disbursement of official and private disbursement/investment to developing countries	2175
Table 11.4	Official 2002 development assistance (ODA = foreign aid) as a percentage of all investment inflows to Sub-Saharan	2177
Table 11.5	Official Development Assistance (ODA) from 2003 to 2006 at Current prices (2006, US\$ Millions)	2194
Table 11.6	Net Overseas Development Assistance (ODA)/Foreign Aid to Africa, 1996-2001	2197
Table 11.7	Change in indicator species populations, Okavango Delta	2227
Table 11.8	Change in indicator species populations, Southwestern Botswana	2230
Table 11.9	Comparative population numbers of some key species in 1987 and 1994 for the Southern Kalahari system	2231
Table 11.10	Sub-Saharan Africa UNEP-WCMC data base of IUCN management categories	2287

Table 11.11	Definitions of IUCN Protected Area Management Categories	2293
Table 11.12	Game population estimates for the Lake Mburo ecosystem, 1992-2002	2307
Table 11.13	Revenues from different forms of landuse, Lake Mburo	2310
Table 11.14	Projects financed by the support for community-initiated projects (SCIP) fund and their achievements, Lake Mburo National Park, Uganda	2311
Table 11.15	Multiple use of wildlife maximizes profit, South Africa	2321
Table 11.16	Quota utilization and game fee revenues for the Lake Mburo pilot sport hunting scheme in 2001/2002	2323

FOREWORD

AFRICA! The name sparks the imagination of people throughout the world. For many, it is a land of charismatic mega-fauna and unfathomable biodiversity. For others it holds interest because of its rich and complex history, culture, and geopolitics. For still others, it speaks of opportunity to exploit its vast resources. For me, as a child, Africa was a place that captured my imagination like no other – wild and full of creatures of all manner and shape. It still does, but my collective knowledge of Africa, beyond its wildlife and conservation, is limited to what I read in newspapers and magazines. This book provides the portal through which that collective knowledge grew to encompass many facets of Africa, its people, and its history.

By modern standards, Africa is plagued by civil/political strife, poverty, and unsustainable population expansion. The continent has tremendous resources, yet it seems that most of the people do not benefit from these riches. Therefore, our thoughts about Africa often take on a sense of hopelessness about its future, its people, and its wildlife. In this book, Drs. Andre DeGeorges and Brian Reilly bring a wealth of experience to their assessment of the past and current state of African conservation, particularly wildlife conservation, but also of fisheries, water, vegetation, and soil conservation. Their effort is an odyssey through time with a central focus on African cultural history, the history of failed conservation and “development” plans by foreign organizations and governments, and the effects of these failures and historical events with respect to African ecology, people, and cultures.

This is a remarkable book, both in its scope and depth. Its greatest value is that it has something of interest for everyone, and perhaps that is something that may also find critics. The authors hold strong opinions and criticisms of past and current African conservation, economic aid/development, and “outside” efforts to influence African conservation. They present a litany of failed conservation and humanitarian projects across the continent. Thus, this book will surely be controversial. Although I disagree with some of their assessments, the benefit of the exposure to a vast array of historical failures changed my thinking about the role of external influence on the internal affairs of Africa. Disagreements are healthy, but they are ancillary to the authors’ theme and intent of exposing a broad range of recent failures in African conservation and humanitarian efforts.

They begin their journey with the explicit recognition that humans evolved in Africa. This hypothesis is generally accepted by anthropologists, and seems unrelated to a book on conservation, but it sets the foundation for later theses that emerge throughout the book. One of which is the notion that if wildlife and humans co-evolved in Africa, then that should have suggested to colonialist powers that the Africans they subjugated actually might know how to manage and conserve their wildlife and natural resources. DeGeorges and Reilly provide extensive historical background to demonstrate that well developed resource management systems were in place all over Africa and these were either not recognized or discarded in favor of “superior” management systems (deemed so by the colonialists). They also suggest that colonialists wanted to disenfranchise the indigenous Africans from their resources for their own personal gain. The reasons for this are many, but clearly the intent of invasion of another people’s territory by colonialist powers was not to assimilate the values and culture of the invaded cultures as their own. Moreover, the authors propose that there was not even recognition among colonialists that indigenous Africans had well developed viable natural resource conservation systems. The colonization of Africa by

foreign powers largely caused the loss of indigenous resource systems over much of Africa, which the authors propose is partly at the root of Africa's current conservation crises. However, the authors also contend that a new form of colonialism (neo- or eco-colonialism) has been occurring within the conservation and resource exploitation arenas because well meaning organizations and others are making the same mistakes as in the past – the real interest is not in what Africans and Africa needs but what they want from Africa in terms of conservation. This neo-colonial conservation may possibly lead to more degradation of African resources and ultimately represents a direct threat to African conservation, its people, and its biodiversity.

Lest one is left with the impression that Western cultures are all bad and indigenous cultures are all good, the authors set a historical background that shows many of the ills of humanity were present in Africa prior to Western colonialism (for example, slavery, intertribal warfare, forceful appropriation of other's land, and religious genocide). Thus, one cannot place all of the ills of modern Africa at the feet of Western countries because past African history has its own sordid elements that complement some equally tragic current political situations (the current situations in Zimbabwe and Darfur for example). The history presented in this book clearly shows a continent that had been in constant cultural evolution while maintaining substantial harmony in land and resource conservation. Nevertheless, the cultures of Africa were complex and had well developed social and resource allocation systems before colonial powers arrived – many of which were quite different from area to area but achieved the same conservation goals. It will be obvious to readers that pre-colonial Africa was quite different than modern Africa because of a high ratio of land/resources to human population density. Yet, strategies existed such as spreading the risk when using multiple resources, division of labor among resource users, rules of conduct when using resources, and active management interventions, all of which suggest

a high degree of sophistication and codification of indigenous ecological knowledge. African systems were developed through trial and error, and hence not “scientific”. But the price of failure was death or severe deprivation so the selection forces over the eons to develop sound systems were strong. The authors detail the remarkable diversity of resource use and allocation systems that many cultures and tribes had developed in Africa, which establishes a foundation that Africa is a singularly complex continent in every facet. Readers will be struck that other “modern” constructs of resource management principles (such as land rest-rotation, adaptive management, dispute resolution) were well established in pre-colonial Africa.

DeGeorges and Reilly discuss in detail the importance of hunting to Africans, in both historical and modern terms. Hunting in Africa is often portrayed in Western media as a dichotomy of either the bushmeat-endangered species trade-poaching triad or trophy hunting by wealthy visitors to Africa. Usually, both are presented in a negative light. Yet the authors show that hunting has deep cultural and mystical roots in Africa and that wildlife has provided a utilitarian foundation (protein, hides, and other products) for its people. They are also critical of some facets of the modern dichotomy, but conversely supportive of the continued exploitation and use of wildlife by both indigenous people and those who travel from far lands to hunt African game. In fact, they provide examples of African hunting that show trophy hunting is neither a modern invention nor Western-developed activity because some African cultures practice various forms of trophy hunting. There are many statements about culture by the authors, which will certainly open the door for scholarly investigation by students of African cultural diversity. In essence they deem the survival of African wildlife and its habitat to be directly linked to its potential for exploitation by Africans and foreigners in a sustainable manner for meat production and for trophy hunting – this is the

paradox of hunting in modern society, for many wildlife species to survive they must have economic value.

The authors assess many failures of past and current conservation projects in Africa. It would be easy to simply say that Africa's conservation ills are the result of failed foreign intervention but that would be wrong. The historical accounting makes one reflect on the inequities and strife that Africans wrought on each other over time that were independent of external influences. For example, when the authors discuss cattle and grazing, one starts to think about the developing inequities within many African groups where a king or the elite of the tribes had special privileges with respect to cattle ownership or grazing rights. So the historical accounts allow the reader to place some of the modern failures in context and perspective – Africans were not supremely wonderful and “Westerners” were not all bad because certainly bad things were happening to human dignity and equality well before the arrival of “Westerners” *en masse* to the continent. The contrast between Western and indigenous politics and interventions does not even consider the forceful spread of Islam over much of northern Africa, which had its own consequences for the indigenous cultures and beliefs and continues today.

Why have so many seemingly well-meaning modern economic development or conservation projects failed in Africa? This question also is complex and is explored in great detail by the authors. The strategy by the authors is to state a problem, then present their own experience with a project that reflects the problem, and then follow the case history by a synopsis of what went wrong and often what could have been done to prevent it. Some failures can be classified as “silly mistakes” (Caughley and Gunn 1996, “Conservation Biology in Theory and Practice”). An example of a silly mistake is creating a conservation or development plan that may make social sense (desire to help people) but is

doomed to failure because there are obvious negative ecological consequences of a plan (disrupting a natural hydrologic system in order to create an irrigation system). A narrow, short-term potential benefit would be far outweighed by a widespread, long-term negative effect. Other plans fail because they are politically expedient (an external government gives aid to the host country to win political favor), have good goals and intent but the wrong methods or constituency (community-based hunting programs), or are attempts by outside groups to influence government policy (attempts to restrict hunting or culling of wildlife or use of specific land areas). Still other failures occur because traditional systems are discarded in favor of Western systems, which may not be appropriate to either the ecological setting or the manner in which people use and share resources. The bottom line for the authors is that local people have to have both a vested interest in and a direct benefit from any conservation plan before it will succeed. Many plans fail for obvious ecological reasons, but many others fail because external interests do not understand or consider meaningful local interest. The authors believe that conservation in much of Africa is doomed to fail if local people do not benefit directly from conservation and do not have a controlling interest in local conservation plans.

The message the authors continually portray is that Africa is historically and culturally diverse, but so are the problems that now beset the continent and its people. The authors' diverse examples of failed programs and problems express this diversity in a way that is both sad and interesting. There are so many reasons why non Africans are interested in Africa that a single model cannot be used to explain the failures or provide solutions. I suggest to readers that they maintain an open mind as they read the book to gather all perspectives. The book is like a tapestry; one cannot view a single thread and understand or appreciate the whole.

I learned a great deal about Africa reading this book, but I was struck by the enormity of the problems and the scale of failures – some well meaning and others not. Their discussions of the interplay and scale of global economics, commodity subsidies, foreign government economic policies, and the power and goals of multinational corporations was like a spider’s web that has trapped the poor of Africa. The discussion portrayed CITES (Convention on International Trade of Endangered Species) and the ESA (U.S. Endangered Species Act) in a relatively negative light, which was enlightening to me because I support the basic premise of both CITES and the ESA. The influence of special interests (particularly anti-hunting groups) to control conservation in Africa is “eco-colonialism” in the eyes of the authors. These special interests have attempted to block African use of wildlife resources, without compromise in some situations, and can be viewed as a modern mechanism to keep poor Africans disenfranchised from wildlife and land – the authors also believe this is a form of “eco-genocide.” This control is done directly through CITES Conference of Parties actions or indirectly through pressure on Western governments to exert influence on or threaten African countries with lower economic aid.

The authors’ passion and love for Africa and its people comes through strongly in this book as does a message of frustration. The documentation of failed economic aid, conservation failures, global economic impacts on poor people, and political corruption can be numbing at times such that one wonders “can Africans lift themselves out of poverty and despair?” This will be difficult, but the messages in this treatise are clear: imposition of Western ideas and resource management systems have largely failed in Africa, African conservation must seriously integrate indigenous people with conservation if wildlife and its habitats are to survive, economic globalization is having huge negative impacts on Africa and its people, external government policies and pressure have negative influences on African nations’ internal politics and economics, the cycle of dependency of

African nations on donor handouts needs to be eliminated, Africans need to regain control of their land and their natural resources, and African conservation should ultimately be led by Africans. The authors suggest that although the “West” values Africa and its resources, the examples show that it has not done well in providing either effective aid or advice to Africans. They believe this will ultimately have great consequences for both Africa and the rest of the world. Despite the many examples of conservation and development failures, the authors are not anti-government, anti-aid, anti-West, or anti-hunting. Their case histories of failures reflect the way in which much aid, many governments, and many special interests groups either have sinister motives and express actions that hurt Africans and African conservation or their aid and actions are ill advised.

Everyone who loves Africa, who works in Africa, or sets policy in or out of Africa should read this book. DeGeorges and Reilly establish a recurring theme that Africans should control their own destiny and at this time they don’t. The details in their book simply support this theme. As I read this book, the thought occurred to me: for those who are not African but who work in Africa, why do you do it? Are you part of the solution or part of the problem? Does your effort result in the development of leadership or self-sufficiency among Africans with whom you work or depend upon? These questions require careful introspection and self-honesty. The answers should tell you whether you should either continue your work, continue your advice to Africans or rethink your motives and priorities regarding your work in Africa.

The authors recognize the daunting challenge of reversing the downward spiral of both African conservation and the living conditions of poor Africans. Both will require aid, but the right type of aid - aid that benefits people directly and not corrupt politicians. They recognize and support many of the humanitarian and watchdog organizations working in Africa. They recognize the situation is so

dire that Africa's best and brightest are leaving the continent when the opportunity arises (the “brain drain”) and this must be reversed if Africa is to meet the challenge of globalization or self sufficiency. Africa, its people, and conservation of wildlife are in crisis – this is clear. What is not clear is what should be done and who should do it? Here the authors conclude their *magnum opus* with a recapitulation of the issues and present a way forward. This way will not be easy nor are they naïve enough to think that it will be, yet it is a framework that everyone should think about and consider when engaged in Africa. At its core, is the recognition that Africa belongs to its people, of whatever race, and that the wildlife and resources I dreamt about as a child requires this acceptance if they are to be conserved.

R. J. Gutiérrez, Gordon Gullion Endowed Chair in Forest Wildlife Research, Department of Fisheries, Wildlife, and Conservation Biology, University of Minnesota

PREFACE

In the first decade of the 21st century the state of Africa as a continent has become a very topical issue. The authors, as conservation practitioners having witnessed first hand the state of the continent in terms of its conflicts, corrupt and ineffective government and general inability to compete on the world stage in juxtaposition to its wealth in resources and people and are forced to ask how this came about, and the likely consequences for the wildlife with which we are so intimately involved.

The future of the ecosystems and protected areas of the subcontinent that are etched into the minds of generations of First World children have a future that is fundamentally tied to two issues – neither of which surface in the minds of Westerners that so dearly want to ensure the survival of the wildlife riches of Africa; people's survival and trade in commodities.

As we contemplate issues protected areas and the supporting ecosystems are inundated with people forced to scratch a meager existence from their surrounding natural resources whilst the world's commodity traders exchange Africa's hard won resources whilst offering ecotourism opportunities to First World, would be Hemingway's, the bulk of the proceeds skillfully maneuvered to destinations other than Africa.

In reviewing the potential future of conservation on the subcontinent, the authors have been forced to take a few steps backwards in considering the history of conservation on the subcontinent and in considering case studies and the role of outside role players in Africa's conservation. We have come to the conclusion that in the absence of organized development in Sub-Saharan Africa we may lose all the protected areas and their associated wildlife in the next generation.

Clearly Sub-Saharan Africa's conservation problem arises in the existence of charismatic mega-fauna – survivors whilst the rest of the Pleistocene contingent very rapidly joined the list of the extinct in recent natural history. We ponder the role of co-evolution between man and this wildlife in Africa (contrary to attempts by First World scientists at proving otherwise) and its survival to modern times. Our research has shown that man in pre-colonial Africa adhered to many societal rules that related to the use of natural resources and the need for “conservation” was absent.

In ancient times already, the then civilized world manifested its fascination in the Dark Continent in its collections of animals and trade in metal and wildlife products whilst already forming negative opinions of the inhabitants. We review the upheavals of colonialism, where similar to the North American experience, the sedentarization of people was largely motivated by control of populations and their re-education in Christian ways. This was attended by the paradigm shift of people from nomadic pastoralism with its innate rotation of resource use to sedentary agriculture in ancient soils and arid environments incapable of sustaining temperate climate First World high yield agriculture. The removal of the limitations of constant movement, disease and guaranteed food supplies have directly resulted in population numbers that now burden Sub-Saharan Africa. Concomitantly the colonist's eradicated wildlife (as a disease reservoir and a cash cow) and established enterprises linked to provision of cheap resources to the colonial powers.

The post colonial period saw Sub-Saharan Africa's white political elites replaced by black political elites that very quickly became polarized in the Cold War tug of war. The United States, as the pre-eminent post world war world power, has dabbled in many areas of the subcontinent using either surrogates or its agencies.

Foreign aid became the tool of influence most of which flowed back to the country of origin. The focus was on infrastructural development projects but without due concern for people and environments disrupted in the process or the recipients ability to maintain this infrastructure. To this day Africa remains clearly demarcated in terms of ex-colonial power influence and strong ties to London, Lisbon, Paris and Berlin.

Multinational corporations and a plethora of conservation non-governmental organizations continue to hold sway in many Sub-Saharan African countries, whilst the raw materials flow unabated northwards and people languish in poverty. An in-depth analysis of community based natural resource management projects has been included by the authors.

The exception to the above has been South Africa where the white Afrikaner threw down roots and developed a First World agricultural society based largely on the temperate grasslands of its central inland plateau. The discovery of gold fueled the creation of a world class industrial complex, and even though the Afrikaner commandos lost their war of independence against Britain, this small country enthusiastically embraced the 20th century. Its ultimately failed social experiment of “Apartheid” with its marginalization of the black majority saw its industries accelerate to the fore in arms development and production, having gone nuclear in 1979. Post 1994 the subcontinent has seen South Africa’s soldiers replaced by its entrepreneurs, professionals and scientists as the conduit for the development of the subcontinent. Although South Africa itself teeters nervously in dealing with poverty and unemployment, crime, illegal immigration and brain drain, its neighbors derive massive benefit from its economic muscle.

It is against this backdrop that the authors build an argument that unless orderly development takes place on the subcontinent attended by devolution of resource

control and beneficiation of resources, that Sub-Saharan Africa will ultimately lose its protected areas to human pressure, whilst preservationist NGO's mutually backslap one another on non-existent successes and raise more money on perceived threats to species. There is still much wildlife in Sub-Saharan Africa, but with shrinking habitats caused by people forced to scratch out a living – this in spite of Governments not because of them.

Our discussions and arguments within this tome may at times indicate that we are anti-hunting or anti-foreign aid but quite the contrary – we make an all encompassing case for the utilization of Africa's resources with beneficiation of people on the ground as the primary outcome. As we indicate, foreign aid, used for important development catalysts such as health, nutrition and education is important. However, when 70 to 90% of foreign aid returns to the country of origin, when the West takes more than it gives, when foreign aid becomes a form of global welfare - more important than foreign direct investment and the transforming of Sub-Saharan Africa's raw products on the continent, or it allows leaders to shirk their duties of reinvesting the subcontinent's wealth back into development as opposed to weapons of war, then yes we have a problem with foreign aid. Until Sub-Saharan Africa urbanizes and industrializes, habitat loss from large numbers of people scratching an existence from the land will be the biggest threat to the last great assemblages of charismatic Pleistocene mega-fauna.

Professor Brian Kevin Reilly

ACKNOWLEDGEMENT

We would like to thank the following persons and organizations for their input both technically and morally to this book:

Tshwane University of Technology's Department of Nature Conservation that gave us the time and space to compile the information here within.

Researchers and NGOs too numerous to mention, but whose permissions will be seen throughout this book.

To the Western donor community, African governments, as well as the safari, professional and sport hunting industry that educated us as to their agendas for conservation and development in Sub-Saharan Africa.

To our Project Noah students from all over Sub-Saharan Africa who provided insight into their diversity of cultures and the plight of their people and natural resources.

Finally, to the many Africans with whom we have worked, but especially to the traditional hunters, fishermen and other resource users who have sensitized us to their plight and humbled us with their kindness, generosity and knowledge of nature conservation and wildlife behavior.

May God bless you all!

INTRODUCTION

“There is nothing new in the world except the history you do not know.” Harry Truman In: Kinzer (2003).

“To understand the future you must understand the past”
(Kibonde, *pers. comm.*).

This book takes a fresh look at Sub-Saharan African conservation and development at the beginning of the 21st century and suggests a possible way forward. Parks and protected areas are rapidly becoming hard-edged, surrounded by a human population living a subsistence life style, and expected to increase from 622 million to between 1.5-1.8 billion people in the next 50 years. The soils and savannas of the subcontinent, as currently used, have far exceeded their capacity to provide an acceptable quality of life for the majority of rural inhabitants. Undernourishment and malnutrition, poverty, high infant mortality, a lack of educational opportunities and poor health care are endemic. To make matters worse, economies tend to be stagnant or declining with negative per capita Gross Domestic Products (GDPs).

Given these pressures, one has to ask, how the natural systems and revered mega-fauna of Sub-Saharan Africa can possibly be expected to survive this human wave flowing over the continent. Already, there are only scattered pockets of wildlife left across the Sahel, a condition which is the combined result of man-induced climate change and habitat degradation linked to agriculture and livestock. This book delves into how the subcontinent has ended up in this precarious situation.

The book draws on the authors' combined 50 years of experience in ecological policy and planning for the U.S. government in the U.S., East and Southern Africa and the Caribbean, as well as for Sub-Saharan African governments, especially those of Senegal, the Gambia, Guinea and South Africa. It furthermore benefits from their representation of the sport hunting/conservation fraternity on the subcontinent, as well as from what has been learned from traditional hunters and other resource users in countries ranging from Senegal to Zambia. This book assesses the successes and failures of conservation and development to both conserve Sub-Saharan Africa's wildlife and other natural resources, as well as to sustainably use these resources as catalysts for development of the subcontinent and advancement of its people.

It analyzes Sub-Saharan African ecological systems from the top of the mountain down to the edge of the sea and specifically examines their ability to support increasing human and livestock populations. The reader is led from pre-historical times into the beginning of the 21st century. Case studies are used to support key objectives and answer key questions posed by the book, and are drawn from the authors' actual experiences in the field as well as from relevant literature. A discussion about the possible way forward is provided.

Unlike most overviews of conservation, which are narrowly focused, it takes what appear to be disjointed unrelated issues in Sub-Saharan Africa and demonstrates how there is a synergistic effect between different sectors that are impacting on the sustainable management of Africa's natural resources and by implication its economies, political stability, and ultimately the well-being of its people.

Map of Sub-Saharan Africa

This following is discussed:

Prehistoric Africa

As background information, it is shown that Africa is the only continent in which humans co-evolved with wildlife. Also, there is a brief discussion about the evolution of modern human's physical, mental and social characteristics as a result of the hunting imperative.

Pre-Colonial Africa

An overview is provided of pre-colonial civilizations in Sub-Saharan Africa that were every bit as advanced as many European countries, co-existing with nature until the arrival of the European colonial powers. It also reviews pre-colonial civilizations' understanding of the ecology and dynamics of managing their natural resources, as well as their system of controlled access to these resources through social norms and religious beliefs of small-scale rural societies.

It is demonstrated throughout the presentation that until colonialism, humans and their actions (e.g., burning, grazing livestock, harvesting of fuel wood and charcoal) have been critical to the maintenance of wildlife habitat, including savannas, tropical grasslands, montane forests and dense humid tropical forests. The book assesses shifting slash and burn agriculture with long fallow fields developed by Africans to account for the poor soils, especially in the savannas that constitute 70-75% of Sub-Saharan Africa. The surgical removal of Africans from the rural landscape first by colonialization and today by modern conservation means that Western approaches have failed to recognize this role along with their strong cultural ties to and economic dependence on wildlife and associated natural systems.

Colonial and Post Independent Africa

It examines how the imposition of Western systems of governance and consciousness has changed the way in which Africans relate to wildlife and natural systems. It also looks at the preconceived view that Africans were both without civilization and had little or no knowledge or control over the management of their resources before the advent of colonialism. In addition, there is discussion about how European imperialism in Sub-Saharan Africa recreated the landscape in the eyes of the conqueror. This situation is compared to the conquest of North America, both in the treatment of indigenous people, recreation of the landscape, and the expropriation of wildlife and other resources including land.

It also considers the introduction of an inappropriate “plantation” or monoculture cash-crop agriculture in many areas of the subcontinent to provide cheap raw products to the “mother country.” It is demonstrated that this practice went ahead with little understanding that soils were/are only marginally suited if not completely inappropriate for permanent agriculture over a large portion of the subcontinent. The result has been massive soil and environmental degradation.

Misused Technologies

The book assesses the method of compression that was used to make way for colonial plantations, parks and game reserves, and also discusses the human population explosion in the 21st century. Once a viable technology, given current human populations on the subcontinent, the inappropriateness of slash and burn agriculture as currently practiced is also analyzed. In addition, it assesses the misuse of modern technologies in Sub-Saharan Africa and the tropics in general

that has resulted in further environmental degradation, making already uncertain lifestyles that rely on these environments for survival even more precarious. It also demonstrates that Western technologies introduced in the 20th century have the potential to play a vital role in development, but have often been misused, resulting in seriously adverse impacts on the ecology, traditional food production and rural people including:

- **Boreholes:** Boreholes which were inappropriately dug in rainy season grazing areas along with government policies (e.g., sedentarization, disregard for the importance of floodplains for dry season grazing, imposing intensive management systems on extensive pastoralists without appropriate training, land and resource tenure) encouraged over-grazing and savannah degradation across the continent.
- **Dams:** As a spillover from the big dam era in the United States, the idea of River Basin Planning was brought to Africa from the 1960's through to the 1980's. Rivers would be harnessed and controlled by Western technology to capture their energy for a range of purposes, including electricity, irrigation and transport. In Sub-Saharan Africa, to date the net result has been the destruction of downstream floodplains greatly reducing the carrying capacity for these systems to support man, livestock, fish, waterbirds and wildlife. The lofty goals of food-self-sufficiency and cheap electricity for all have not been achieved.
- **Inappropriate coastal tourism development:** Here the treatment and discharge of sewage and “gray” (wash/bath) water, as well as economic development have had a negative impact on maintaining key habitats such as coastal lagoons, mangroves, grass beds and coral reefs, and have also adversely affected related fisheries and fisher communities. The Caribbean experience serves as an example from which many lessons can be learned, especially for the east coast of Africa, which is just beginning

to develop its coastal areas. Similar signs of inappropriate development are slowly emerging from Mozambique to the Red Sea.

Community Based Natural Resources Management

It analyzes Community Based Natural Resource Management (CBNRM), a new concept emerging out of Southern Africa. CBNRM attempts to integrate people into conservation through material rewards (meat and money) in order to take pressure off the natural land-based systems. A major problem is that CBNRM has become a pawn in the international ideological battle between the Western-based animal rights and sustainable use movements. Both ideologies are at fault for not dealing with the more pressing issues at hand such as land and resource tenure, the continued existence of neo-colonial relationships between government and the private sector that results in the inequitable distribution of benefits to rural communities, lack of educational opportunities and alternative livelihoods for rural Africans, as well as the low resource to population ratio. This cries for broader solutions of which conservation only forms a very small part of the larger puzzle. The evolution, strengths and weaknesses of CBNRM are analyzed and recommendations made for the way forward.

Onset of the Cold War and Eventual Globalization

During the 20th century, Sub-Saharan Africa's human population increased 5.5-6.5 times. The latter half of the 20th century saw "winds of change" sweeping across the region. First came independence from the colonial powers, followed by the Cold War where Sub-Saharan Africa served as a chessboard for the superpowers playing out their ideologies, each striving to control global politics. At the dawn of the 21st century, Sub-Saharan Africa is being adversely impacted by globalization and a desire for continued access to cheap natural resources to

drive Western and more recently China's economies. The current and potential role of the international private sector in natural resource management and development of local, national and regional economies is examined.

Impacts of National and International Policies on Governance, Conservation and Development

It demonstrates that given the current human population and its projected growth in Sub-Saharan Africa, conservation on its own will fail, as natural systems will have a difficult time surviving the onslaught from this human wave of poverty living rural subsistence lifestyles. The situation will remain serious, even if 50% of the population of Sub-Saharan Africa is urbanized by 2020. The impacts of foreign aid, structural adjustment, debt relief, Convention on International Trade in Endangered Species (CITES), trade, subsidized agriculture in the West and food dumping are discussed as they impact upon Africans, governance, economies and conservation on the subcontinent. Cultural constraints linked to these development and conservation policies/tools are also analyzed.

The Way Forward

A vision for the way forward is provided that must be driven by Africans, and which fits into and is compatible with their socio-economic and cultural mores. The authors contend that in order to take the human population pressure off the rural resource base, Sub-Saharan Africa will be required to go through the same urbanization and industrialization process as the U.S. and Europe underwent in the 20th century. At the same time, however, there must be improvements in the management of soil, water, vegetation and wildlife in rural areas. Ideas on how to achieve these goals are presented in the final chapter. Ultimately, the future of

modern civilization may be more closely tied to and dependent on the development of Sub-Saharan Africa than most people realize.

Chapter 1

1.0 PRE-COLONIAL SUB-SAHARAN AFRICAN CIVILIZATIONS AND CO-EVOLUTION WITH WILDLIFE

“The vast majority of the world’s biological diversity is not in gene banks, zoos, national parks or protected areas. Most biological diversity is in landscapes, whose great collective accomplishment is to have conserved the great variety of remaining life forms, using culture, the most powerful and valuable human resource, to do so” (Nietschmann, 1992 *In:* Langton, 2003 *In:* Adams & Mulligan, 2003).

While many assume that traditional African societies were backward, this is far from the truth. Sophisticated kingdoms and empires existed such as Kush, Nubia, Aksum (Axum), Fulani, Mali, Songhai, Ghana, Sudan, Kanem-Bornu and Hausa states, Luba and Lunda States, Ethiopia, Yoruba, Ashanti, Dahomey, and Zulu. Smaller city-states also developed, often linked to trade, such as Lamu, Malindi, Mombasa and Mwene Mutapa (Monomotapa) (Figure 1.1). These societies were well structured with organized and functioning systems of governance. Armies served to protect and expand their realms of influence and controls over access and management of resources.

“When they (European navigators) reached the Bay of Guinea and alighted at Vaida, the captains were astonished to find well-planned streets bordered for several leagues by two rows of trees; for days they traversed a countryside covered by magnificent fields, inhabited by men in colorful attire that they had woven themselves! More to the south, in the Kingdom of the Congo, a teeming crowd clad in silk and velvet, large States, well ordered down to the smallest detail, powerful rulers and prosperous industries. Civilized to the marrow of their bones...This flowering the European conquistadors destroyed as they advanced” (Quote Frobenius *In:* Diop, 1974; The Sankofa Project, 1999).

1.1 PRE-HISTORIC AFRICA – THE CRADLE OF MANKIND

1.1.1 Geological Timetable and the Evolution of Humans

Humans and their ancestors evolved in Africa. The key geological time frame for this process is structured as follows (MacRae, 1999; USGS, 2004):

Mesozoic Era, 245-65 million years ago (BP) (USGS, 248 - 65 million years ago)

- **Triassic Period**, 245-190 million years ago (USGS, 248 - 213 million years ago)
- **Jurassic Period**, 190-136 million years ago (USGS, 213 - 145 million years ago)
- **Cretaceous Period**, 136-65 million years ago (USGS, 145 - 65 million years ago)

Cenozoic Era, 65 million years ago to the present (USGS, 65 million years ago – to the present)

- **Tertiary Period**, 65-2.5 million years ago (USGS, 65 - 1.8 million years ago)
 - **Paleocene Epoch**, 65-54 million years ago (USGS, 65 - 55.5 million years ago)
 - **Eocene Epoch**, 54-38 million years ago (USGS, 55.5 - 33.7 million years ago)
 - **Oligocene Epoch**, 38-26 million years ago (USGS, 33.7 - 23.8 million years ago)

- **Miocene Epoch**, 26-7 million years ago (USGS, 23.8 - 5.3 million years ago)
- **Pliocene**, 7-2.5 million years ago (USGS, 5.3 - 1.8 million years ago)
- **Quaternary Period**, 2.5 million years ago to the present (USGS, 1.8 million years ago – to the present)¹
 - **Pleistocene Epoch**, 2.5 million to 50,000 years ago (USGS, 1.8 million - 8,000 years ago)
 - **Holocene Epoch**, 50,000 years ago to the present (USGS, 8,000 years ago – to the present)

The first mammals evolved from land-living reptiles as small, furry, warm-blooded, shrew-sized mammals about 190 million years ago. They co-existed, living side by side with the more dominant dinosaurs during the Jurassic and Cretaceous Periods. About 65 million years ago at the beginning of the Tertiary Period, there was an extensive evolutionary radiation of mammals as they exploited and filled the many niches that were vacated by the massive extinction of dinosaurs (MacRae, 1999).

The Cenozoic Era is known as the “Age of Mammals”. Primitive mammals that existed in the final phases of the Cretaceous Period, about 65 million years ago, included multituberculates, which evolved into monotremes such as the duck-billed platypus and marsupials with descendants such as the kangaroo and

¹It should be noted that some minor differences exist between time scales as estimated by different references. There is, however, a more conspicuous difference between MacRae's (1999) estimate that the Pleistocene Epoch dated from 2.5 million to 50,000 years ago and most other references which place the same epoch between 1.8-1.65 million to 12,000-8,000 years ago (Burkhardt, 1995; USGS, 2004; UCMP, 2004; Illinois State Museum, 2004).

opossum. There were also placentals from which the earliest primates developed 65 million years ago (MacRae, 1999).

The order primates can be subdivided into two suborders (MacRae, 1999):

- Prosimians (before apes), including lemurs, sifakas, aye-ayes, tarsiers and lorises (e.g., galago); and;
- Anthropoids, including monkeys, apes and humans.

The split between these two suborders began during the Oligocene Epoch in Africa. The anthropoids rapidly spread throughout Africa, Europe and Asia. The New World monkeys (now restricted to Central and South America), the Old World monkeys, who came a little later on, (now distributed in Africa and Asia), as well as apes and humans all began with a common ancestor some 30 million years ago (MacRae, 1999).

In the early Miocene Epoch, Africa's climate was warm with high rainfall and covered in tropical forests with apes forming a substantial portion of the mammalian fauna. The *Proconsul* of this period is believed to be a common ancestor of both the great apes and humans. Evidence suggests that the split between humans (Family Hominidae) and the great apes of Africa (Family Pongidae) occurred during the late Miocene Epoch, the gorilla separating from the ancestral stock about 9 million years ago and the chimpanzee about 7 million years ago (MacRae, 1999). Peterson (2003) places the separations as follows:

- The orangutan split off about 12 million years ago with 96.4% of its genetic material (DNA) identical to that of modern humans;
- The gorilla split off about 7.5 million years ago, sharing 97.7% of its genetic material with modern humans;

- The chimpanzee and bonobo split off 6 million years ago, sharing 98.7% of its genetic material with modern humans.

This means that the modern human is genetically closer to a chimpanzee and bonobo than a zebra is to a horse or an African elephant is to an Indian elephant (Peterson, 2003). Diamond (2005) argues that humans' co-evolution with wildlife in Sub-Saharan Africa and these close genetic ties are the primary causes for diseases such as HIV/AIDS, as the latter requires "the least adaptation to jump species" (see Chapter 5, Section 5.8.1, Linking HIV/AIDS to the Bushmeat Trade).

The oldest fossil thought to be in the family of man is the *Ardipithecus ramidus* from Ethiopia, dated at about 4.4 million years ago, though an incomplete skeleton makes it impossible to determine if it was bipedal (walked on 2 legs). The 4 million year old *Australopithecus anamensis* from Kenya is the oldest confirmed bipedal ancestor of man. It is hypothesized that climatic change associated with the Terminal Miocene Event caused the extensive forests and woodlands in Africa to shrink in favor of drier open savanna and grasslands, causing the modern human's ancestors to lose their arboreal security and requiring them to become bipedal in order to access the abundant savanna food supply, while at the same time avoiding predators. In recent times, however, the savanna hypothesis has been challenged (MacRae, 1999).

First found in Ethiopia, subsequently in Tanzania by Mary Leakey and finally in Sterkfontein, South Africa, the *Australopithecus afarensis* "Lucy" is dated to be up to 3.8 million years old and postulated to be the ancestral stock from which subsequent species evolved. The *Australopithecus africanus* discovered at both Taung and Sterkfontein, South Africa was most likely on the direct lineage leading to the modern human. A side-branch which became extinct, *Paranthropus spp.* (2.5-1.0 million years ago - Hilton-Barber & Berger, 2002) is

also believed to have arisen from *Australopithecus afarensis* (MacRae, 1999). Though research continues, Berger (1998) postulates, based on a combination of skull and limb comparisons, that *Australopithecus afarensis* (3.8-3 million years ago - Hilton-Barber & Berger, 2002) emerged as a human-like biped but eventually died out, while *Australopithecus africanus* (3.1-2.1 million years ago - Hilton-Barber & Berger, 2002), emerging at almost the same time in Southern Africa eventually evolved into *Homo habilis* (2-1.6 million years ago - Hilton-Barber & Berger, 2002) as it migrated north.

The fossilized lower jaw and skeletal remains, discovered at Olduvai Gorge, Tanzania by Jonathan Leakey and near Lake Turkana by Richard Leakey, are probably the oldest representative fossils of the genus *Homo spp.* to which humans belongs. These remains belong to *Homo habilis*, who evolved from *Australopithecus africanus* about 2.5 million years ago. *Homo habilis* is believed to have been capable of speech, the use of primitive tools (MacRae, 1999) and hunting (Ardry, 1966) with a brain half the size of the modern human's.

Leakey and Lewin (1995) discuss the “turnover-pulse hypothesis” of evolutionary pulses in humans, antelope, rodents and plants, among others at about 5 million (beginning of man) and 2.5 million (first *Homo sp. appears*) years ago, linked to global cooling. It is hypothesized that about 2.5 million years ago, shifting tectonic plates created the Great Rift Valley of East Africa, with the environment changing from a tropical lowland blanketed by green forests to a topographical mosaic of habitats including the dominance of drier climates. This would have resulted in 1) decreasing forest cover with increasing open savanna grasslands 2) humans becoming bipedal and 3) humans developing more athletic bodies and larger brains to cope with the development of stone tools and the need to communicate. These “human traits” are linked to hunting on open savannas as meat became dominant in the human diet.

About 1.8-1.6 million years ago, a new species of *Homo* sp. arose, which was called by various names from *Pithecanthropus erectus* to *Homo ergaster* to *Homo erectus*. It was first discovered by Richard Leakey around Lake Turkana in 1984. Research shows that it displayed an increased cranial capacity, used fire, hunted co-operatively and may have used semi-permanent shelters (MacRae, 1999). *Homo erectus* (2 million years ago to about 400,000 BC) is regarded as the first identifiable true human ancestor (Hilton-Barber & Berger, 2002). Peterson (2003) believes that the mastering of fire and the concurrent development of cooking between 1.7 and 1.5 million years ago significantly increased sources of available nutrition (e.g., roots and tubers) necessary for the development of a larger brain which consumes about 20% of human's total caloric intake.

Homo erectus has been found throughout the world, having migrated from Africa (MacRae, 1999), the first hominid known to have left Africa (Hilton-Barber & Berger, 2004):

- North Africa was reached 1 million years ago;
- China (Peking Man) and Java (Java Man) were inhabited about 800,000 years ago;
- Europe's first inhabitants occurred about 500,000 years ago.

A recent estimate, placing the Java Man at 1.8-1.6 million years of age, as old as their African kin complicates this hypothesis. There is also debate over a recent specimen found in Swartkrans, South Africa, classified as *Homo ergaster*, who used Acheulean hand axes not found among the remains of their Asian cousins. This indicates that cultural exchange and therefore inbreeding did not occur. The Asian species became geographically isolated before the development of the Acheulean culture in Africa (MacRae, 1999).

The discoverer of *Homo ergaster*, Ronald Clarke maintains that it is this species and not *Homo erectus*, which developed into the modern human, *Homo sapiens*. Two hypotheses now exist (MacRae, 1999):

- **Multi-regional hypothesis.** About 1 million years ago populations of *Homo ergaster/Homo erectus* emerged from Africa and spread to Asia and Europe, there slowly evolving into *Homo sapiens* at various widely spaced geographical centers, but without being reproductively isolated.
- **Out of Africa hypothesis.** All populations of *Homo erectus* became extinct between 100,000 and 40,000 years ago². *Homo sapiens* (200,000 years ago to present - Hilton-Barber & Berger, 2002) evolved from a *Homo ergaster/Homo erectus* stock, and a common population of primitive humans existed in Europe and Africa about 400,000 years ago as represented by *Homo heidelbergensis* (600,000-200,000 BC - Hilton-Barber & Berger, 2002) discovered in northern Greece (Petalona Skull), Zambia (Broken Hill Skull – “Rhodesian Man”), Saldanha Man from Elandsfontein, South Africa (300,000 years old) and Florisbad Man near Bloemfontein, South Africa (259,000 years old).

1.1.2 Out of Africa

The “Out of Africa” theory, based on genetic DNA (Deoxyribonucleic Acid) coding analyses has it that evolutionary divergence took place in response to the expanding Sahara desert, which acted as a genetic isolating barrier. The population to the north became the Neanderthals (*Homo neandertalensis*)

² Note that Hilton-Barber & Berger (2002) place extinction of *Homo erectus* about 400,000 BC ≈ 402,000 years ago significantly different from MacRae (1999) and Maywell (2003). Oppenheimer (2003) distinguishes between an African *Homo erectus* that is directly linked genetically to the evolution of modern man and would have died out much earlier compared to an Asian *Homo erectus* that existed until less than 30,000 years ago before dying out with no genetic traces in modern humans.

(230,000-29,000 BC - Hilton-Barber & Berger, 2002) of Europe and the Middle East and to the south of the desert, the first modern humans, *Homo sapiens* (MacRae, 1999).

Homo sapiens have been found ranging from 130,000 to 40,000 years of age in Southern Africa including (MacRae, 1999):

- Border Cave Man, South Africa/Swaziland border,
- Specimen, Klasies River Mouth, southern Cape, South Africa; and
- Springbok Flats Man, Tuinplaas farm on the Springbok Flats of the Northern Cape Province, South Africa.

It is believed then that modern humans spread in a second wave across the globe between 40,000 and 35,000 years ago, differentiating into the various races at a later date (MacRae, 1999; Maywell, 2003).

“Geneticists now believe that all humans alive today are descended from a single man who lived in Africa around 60,000 years ago...All modern humans evolved in Africa and then left in several waves of migration, ultimately replacing any earlier species...It isn't yet possible to establish whether modern man is entirely recent African in origin, or whether there has been 'hybridization/assimilation' between modern and archaic species”. However, “while the most recent male common ancestor identified through the y-chromosome lived 60,000 years ago, the most recent female common ancestor traced through mitochondrial DNA lived around 150,000 years ago. Whether an individual can be identified as our single common ancestor is open to debate. There's almost certainly not an Adam or Eve. Each of our genes has its own history, which could be passed on from different ancestors. It's more likely that a lineage can be traced back to a population of 50, 100, or even several thousand people” (Maywell, 2003).

Oppenheimer concludes that there are no genetic traces in living humans from either the European Neanderthals or Southeast Asian *Homo erectus*.

By around 100,000 years ago, several species of hominids populated the earth, including *Homo sapiens* in Africa, *Homo erectus* in Southeast Asia and China, and the Neanderthals in Europe (Maywell, 2003). The new immigrants to Europe, Cro-Magnon Man, an early *Homo sapiens*, successfully competed with the Neanderthal. Some authors argue that *Homo neandertalensis* was a distinct species (MacRae, 1999), while others hypothesize that *Homo sapiens neandertalensis* was a subspecies (Columbia Encyclopedia, 2004) that had existed for 200,000 years but became extinct 27,000 years ago being replaced by modern humans, *Homo sapiens sapiens* (MacRae, 1999). By around 30,000 years ago, the only surviving hominid species was *H. sapiens* (Maywell, 2003 & Oppenheimer, 2003).

Some researchers place the timing of human's (*Homo sapiens*) movement out of Africa as follows (Maywell, 2003):

- Hominids left Africa around 45,000 years ago (43,000 BC), reproduced rapidly, and settled in the Middle East; smaller groups going off to India and China. Isolated by mountains and sea for many generations, and exposed to a colder climate and less sunlight than in Africa, Asian populations became paler over time.
- Around 40,000 years ago, as the grip of the Ice Age loosened and temperatures briefly became warmer, humans moved into Central Asia. Amid the bountiful grassy steppes, they multiplied quickly. If Africa was the “Cradle of Mankind”, then Central Asia was its nursery.
- Around 35,000 years ago, small groups left Central Asia for Europe. Cold temperatures kept them there. Cut off from other groups, these migrants became paler and shorter than their African ancestors.
- From there, around 20,000 years ago, another small group of Central Asians moved farther north, into Siberia and the Arctic Circle. To minimize

physical exposure to the extreme cold they developed, over many generations, stout trunks, stubby fingers, and short arms and legs.

- Finally, around 15,000 years ago, as another Ice Age began to wane, one small clan of Arctic dwellers followed the reindeer herd over the Bering Strait land bridge into North America. Also isolated, they too acquired distinct physical characteristics.

Many archaeologists, however, believe that Australia, the Middle East, India and China were inhabited much earlier (Maywell, 2003). Geneticist Oppenheimer (2003) argues for a one time exit from Africa via a southerly route. He believes a major shortcoming in estimating the timing of modern man's movement about the globe is that scientific disciplines rely on radio-carbon dating that has a ceiling of about 45,000 year. By using computer modeling, looking at the DNA code (mitochondrial DNA inherited from the female line and the Y chromosome inherited from the male line) in people today and the rate of mutations, Oppenheimer has been able to retrace the genetic tree and determine where certain mutations took place (e.g. Africa, Asia or Europe) and approximately the time when they happened. He hypothesizes that an earlier attempt via a northern route out of Africa 120,000 years ago into the Levant (Israel and the Near East) failed as the earth entered into a period of glaciation about 90,000 years ago causing North Africa and the Levant to enter into a period of extreme desertification. Modern man died out and would not be found in the Levant until 45-50,000 years ago, originating from the southern route out of Africa. He places *Homo sapiens* one time departure from Africa across the Red Sea into modern day Yemen about 80,000 years ago during a period of glaciation when sea level was much lower, passing along a southern coastal route through South Asia (modern Pakistan/Arabian Gulf) with human occupation in China and Australia by 70,000 years ago, and into Central Asia (modern day Kazakhstan, Turkmenistan, Uzbekistan, Kyrgyzstan and Tajikistan) about 40-50,000 years ago

from the Indo-Pacific, via three different routes. Modern man is believed to have first entered Europe from South Asia about 50,000 years ago along the eastern side of the Arabian Gulf just west of the Zagros Mountain range of modern day Kurdistan [through portions of modern Iran/Iraq/Syria], skirting the Mediterranean Sea up through Turkey and then across the Bosphorus Straights. A second migration into Europe took place from South Asia via a Trans-Caucasus route, just west of the mountains and east of the Black Sea through modern day Iran, Turkey, Georgia, Russia and then west, and/or from Central Asia east of the Caspian Sea through Russia sometime after 33,000 years ago. There are strong genetic ties with Europe and the regions of the Caucasus Mountains between the Black and Caspian Seas, as well as with Central Asia. Modern man is projected to have arrived in Siberia about 39,000 years ago from Central Asia. Entry into the Americas is said to be controversial among various scientific disciplines both in time (11,500 to 50,000 years ago) and in the number of migrations, though the majority of founding Americans lines are believed to have occurred before the last glacial maximum between 22,000 and 30,000 years ago (Oppenheimer, 2003).

1.1.3 Evolution of Modern Agriculture in Africa

About 100,000 years ago, humans were able to kill moderately sized prey such as eland. By 50,000 years ago, man had developed the skills and weapons to take on even the largest prey, such as cape buffalo, elephant and rhinoceros. By 40,000 years ago, people living in northern Africa were developing stone points with tangs, which allowed for the attachment of wooden handles and the evolution from less effective all-wood to stone tipped spears (Flannery, 1997 *In: Griffiths & Robin, 1997*).

About 20,000 to 10,000 years ago (18,000-8,000 BC), Later Stone Age populations practiced hunting and gathering. Wild grasses and tubers were

harvested and grinding stones were used to make flour (Martin & O'Meara, 1995). From 10,000 to 6,000 years ago (BP) (8,000-4,000 BC) the Sahara Desert had a Mediterranean climate with relatively high rainfall, fairly large population settlements, lakes, rivers and ponds. A large wildlife population, rich fisheries and food collecting allowed some human populations to become sedentary (Martin & O'Meara, 1995). Smith (1992) suggests that during this wetter phase, from 10,000 to 8,000 years ago, hunters and fishermen (archeological findings of bone harpoons) were scattered from Mali to the Nile Valley in open grasslands, and around Central and Southern Saharan lakes (e.g., Lake Chad and the Araouane lakes north of Timbuktu) and the Nile River.

People in the Nile Valley were intensively exploiting cereals from 17,000 to 12,000 years ago (15,000-10,000 BC), with little evidence of domestication. Egyptians managed the reproduction of wild animals such as gazelles, hyenas, oryx and giraffe, but did not domesticate them (Martin & O'Meara, 1995). Large-scale village farming did not appear until 5,000 BC, when the Egyptians supplemented hunting and fishing with domestic species, including those from Southwest Asia such as wheat, barley and flax, as well as goats, sheep, cattle and pigs (Martin & O'Meara, 1995) (Table 1.1).

Rainfall and soils tended to determine vegetation cover, which in turn influenced lifestyles. In the low and erratic rainfall areas over much of Sub-Saharan Africa's savannas, which constitute 70-75% of the territory (see Chapter 5), mobility in the form of hunting and gathering, as well as pastoralism assured access to regular food supplies without over-harvesting and degrading the environment (see Chapter 2, Section 2.1.5, Mobility as a Means of Managing Natural Resources and Section 2.3.2, Pasture and Water). Human populations were small and the need for highly organized societies minimal. Societies tended to be egalitarian. Dyson-Hudson (1984 *In:* Smith, 1992) considers such groups as being "r-

strategists”³. Pastoralism changed man’s relationship from co-existing with nature to beginning to manipulate it so as to permit accumulation. The accumulation of livestock meant the end of egalitarian societies, resulting in a spectrum of hierarchies from “haves” to “have-nots”, becoming accentuated as humans lifestyles evolved into the final stages of sedentarization: agriculture (Smith, 1992).

With adequate rainfall and/or water (e.g., along floodplains) and soils that permitted agriculture and storage of grains, human populations became sedentary and population densities increased. Eventually empires and kingdoms evolved, classified by Dyson-Hudson (1984 *In:* Smith, 1992) as “*K-strategists*”. The change from gathering to food production allowed human populations to significantly increase and to shift from a nomadic to a settled life. Food surpluses allowed the development of non-food producing specialties ranging from war-making and statecraft to art (July, 1970).

Cotton, which is believed to have originated in Africa, was cultivated at least 5,000 years ago (3,000 BC) (July, 1970). Eventually, indigenous cultigens were developed, such as African yams and palm oil from the forest regions, as well as African rice, bulrush millet, finger millet and sorghum (Martin & O’Meara, 1995). The transhumant lifestyle of herdsmen in open grassland environments militated against a single locus for the domestication of plants and animals (Smith, 1992).

³ In this context, r-strategy is a situation in which large numbers of offspring are produced but few survive. This is in contrast to a more stable environment, where as humans get better control over food supplies a K-strategy develops with lower mortality rates, growing populations possibly decreased reproductive rates and a segment of society freed up from food production (e.g., artisans, soldiers). This facilitates the evolution of empires and kingdoms.

Table 1.1: Examples and origins of early domestic crops from around the ancient world

AREA	CEREALS AND OTHER GRASSES	PULSES	FIBER	ROOT CROPS	MELONS
Fertile Crescent (Turkey, Syria, Iran, Iraq, Jordan)	Emmer wheat (<i>Triticum dicoccoides</i>), Einkorn Wheat (<i>Triticum boeoticum</i>) Barley (<i>Hordeum spontaneum</i>)	Pea (<i>Pisum sativum</i>) Lentil (<i>Lens culinaris</i>) Chickpea (<i>Cicer arietinum</i>)	Flax (<i>Linum usitatissimum</i>)	- -	Muskmelon = Cantelope = Honeydew (<i>Cucumis melo</i>)
China	Foxtail Millet (<i>Setaria italica</i>) Broom Corn Millet (<i>Panicum miliaceum</i>) Rice (<i>Oryza sativa L.</i>)	Soybean (<i>Glycine max</i>) Adzuki Bean (<i>Vigna angularis</i>) Mung Bean (<i>Vigna radiata</i>)	Hemp (<i>Cannabis sativa</i>)	- -	[Muskmelon]
Mesoamerica	Corn/Maize (<i>Zea mays</i> ssp.)	Common Bean (<i>Phaseolus vulgaris</i>) Tepary Bean (<i>Phaseolus acutifolius</i>) Scarlet Runner Bean (<i>Phaseolus coccineus</i>)	Cotton (<i>Gossypium hirsutum</i>) Yucca (<i>Yucca spp.</i>) Agave = Sisal (<i>Agave rigidula var. sisalana</i>)	Jicama (<i>Pachyrhizus spp.</i>)	Squashes = Pumpkin (<i>Cucurbita pepo</i>) etc.
Andes, Amazonia	Quinoa (<i>Chenopodium quinoa</i>) [Corn]	Peanut (<i>Arachis hypogaea L.</i>) Lima Bean (<i>Phaseolus lunatus</i>)	Cotton (<i>Gossypium barbadense</i>)	Manioc = Cassava (<i>Manihot esculenta</i>) Sweet Potato (<i>Ipomoea batatas</i>) Potato (<i>Solanum tuberosum</i>) Oca (<i>Oxalis</i> <i>tuberosa</i>)	Squashes (<i>Cucurbita maxima</i>), etc.
West Africa and Sahel	Sorghum (<i>Sorghum bicolor L.</i>) Pearl Millet (<i>Pennisetum glaucum (L.) R. Br.</i>) African Rice (<i>Oryza glaberrima</i>)	Cowpea (<i>Vigna unguiculata</i>) Groundnut (<i>Voandzeia subterranea</i>)	Cotton (<i>Gossypium herbaceum</i>)	African Yam (<i>Dioscorea rotundata</i> and <i>D. cayensis</i>)	Watermelon (<i>Citrullus spp.</i>) Bottle Gourd (<i>Lagenaria siceraria</i>)

Chrétien (2003) places the appearance of agriculture in the Sahel as about 4,000 years ago (2nd millennium BC) occurring conjointly with the drying of the Sahara area, forest retraction and a human ebb towards a more favorable zone. Chrétien (2003) places the development of sorghum, a cultivar, which complimented garden and root crops, at about 3,000 years ago (1,000 BC) between the Nile and Chad. The local cultigens mentioned above replaced imported winter wheat and barley in the Sahel and further south (Martin & O'Meara, 1995). Sedentarization

intensified during the first millennium BC through the combined action of collectors, fishermen, cattle raisers, cultivators of long-fallow fields and blacksmiths (implying iron technology in West/Central Africa), (Chrétien, 2003).

Bananas (Martin & O'Meara, 1995; Chrétien, 2003), coconuts (Martin & O'Meara, 1995), and the root crop taro (Chrétien, 2003) came from South Asia, while corn and manioc originated from the New World (Table 1.1). Vande weghe (2004) believes that the banana entered Africa more than once, but for the first time about 2,500 years ago (500 BC), mainly *Musa acuminata* originating from India, Indonesia and Southeast Asia, and *Musa balbisiana* originating from India, Burma and the Philippines. By 1,000 BC bulrush millet, finger millet and sorghum were making their way to Asia (Martin & O'Meara, 1995). Giles-Vernick (2002) estimates that maize (corn) reached Africa from the New World sometime after 1,500 AD.

1.1.4 Origins of Domestic Livestock and Pastoralism in Africa

By 9,000 years ago (7,000 BC), the inhabitants of what is today the Egyptian Western Desert were living around ponds and domesticating barley and cattle, well before development in the Nile Valley had taken place. Egypt appears to have domesticated the cat, donkey and wild cattle, cattle not being indigenous to Sub-Saharan Africa. About this time, Asian sheep and goats were also imported (Martin & O'Meara, 1995).

Between 8,000 and 7,000 years ago (6,000 and 5,000 BC), domestic sheep and goats, and pottery making were rapidly adopted across coastal North Africa, replacing hunting as a way of life (Martin & O'Meara, 1995).

Archeological sites further west in the Sahara show remains of sheep, goats and domestic cattle, grinding stones and possible domestication of grasses between 7,000 and 6,000 years ago (5,000 and 4,000 BC) (Martin & O'Meara, 1995). It is believed that all domestic goats and sheep (caprines) in Africa are derived from an exotic progenitor probably originating in the Near East and introduced via North Africa (Libya) and/or Egypt 7,000 to 6,800 years ago (5,000 and 4,800 BC) (Smith, 1992). Vande weghe (2004) suggests that all domestic ungulates of Africa originate from Asian species first domesticated in Asia:

- Goats came from the Ibex, *Capra aegagrus* in the mountains of southwestern Asia;
- Sheep descended from the Arkhar or Argali sheep, *Ovis ammon* of Central Asia, the Urial sheep, *Ovis vignei* from south-western Asia and the European Mouflon, *Ovis musimon* of Asia Minor and Europe.

The origins of domestic cattle are still questioned (Smith, 1992). The theory surrounding this question is that:

- They were introduced from Near East to North Africa and Egypt;
- One or two wild forms of *Bos spp.*, which were indigenous to North Africa during the Pleistocene Epoch, are believed to be the wild progenitors to domestic cattle in Africa. The idea of their domestication possibly coming from introduced caprines;
- They were introduced by a link between Italy and the Maghreb (North Africa) via Sicily 10,000 to 7,000 years ago (8,000 and 5,000 BC).

Baker and Manwell (1980 *In:* Smith, 1992) through genetic studies classified African cattle into the following:

- Category VI: African humpless including the N'Dama and West African Shorthorn;
- Category VIIa: African humped (Zebu mixture);
- Category VIIb: African humped including the Sanga, Africander, Nguni, Ovambo, Pedi.

The stem of this phylogenetic tree is the Near East, but genetic material of the wild cattle, *Bos primigenius*, of the Near East was probably close to the indigenous North African wild stock that existed. This means that the Sanga group could easily have been derived from an admixture of the domestic humpless *Bos. spp.* coming from the North African *Bos primigenius*, and early *B. indicus* (humped short-horned Zebu) entering Africa via Asia. Protein analyses suggest that the African humpless varieties are closest to the European *B. taurus* (humpless, long-horned) and may represent a direct descent from the primigenius type, while blood groupings place the long horned N'Dama (*B. taurus longifrons*) and West African Shorthorns (*B. taurus brachyceros*) (Rege, Aboagye, & Tawah, 1994) between the *B. indicus* (Zebu) and *B. taurus* (Smith, 1992). Vande weghe (2004) states the ancestral species of African cattle are the Aurochs, *Bos primigenius*, a long-horned bovine from Europe, Asia and North Africa, and the Uru, *Bos namadicus*, from India and perhaps the tropical regions of Asia. Attempts by Egyptians at domesticating antelopes failed (Vande weghe, 2004). Poland, Hammond-Tooke and Voight (2003) suggest that both *B. taurus* and *B. indicus* derive from the extinct wild ox of Europe, *B. taurus primigenius*. They believe that while *B. indicus* was domesticated in the Near East about 7,000 years ago (5,000 BC) in the Indus Valley and introduced to Africa via the Horn or East Africa, *B. taurus* was domesticated in Africa (Egypt and/or the Nigeria/Cameroun region of West Africa. The authors furthermore suggest that all African cattle stem from *B. taurus* with a significant to dominating influence by *B. indicus*. The

widely used “*Sanga*” refers to the wide-horned Zebu strain of cattle, with or without a hump, found from Ethiopia to South Africa.

Times given for the drying out of the Sahara vary. Smith (1992) believes this phenomenon occurred sometime after 8,000 years ago (6,000 BC) resulting in hunters and fishermen abandoning much of the area, leaving behind an open ecological niche resulting in spread of pastoralism – that is colonization of an uninhabited grassland niche. Martin and O’Meara (1995) place the timing of this gradual desiccation of the Sahara pushing people south and west into wetter regions at about 6,000 years ago (4,000 BC).

Smith (1992) argues that movement into the Sahel, as dryer conditions pushed the tsetse fly belt back, took place about 4,000 to 3,300 years ago (2,000 to 1,300 BC) permitting the southward movement of cattle. Martin and O’Meara place the spread of domestic cattle south of the Sahara at about 6,000 to 5,000 ago (4,000 to 3,000 BC), supplemented by subsistence hunting and fishing. This also resulted in the development of the N’Dama and West African Shorthorn cattle derived from early domesticated Saharan cattle. They eventually developed blood group selections, becoming trypanotolerant⁴ to sleeping sickness (Smith, 1992). Many believe the N’Dama evolved in the Fouta Djallon Mountains of Guinea-Conakry,⁵ and later spreading throughout the Sudanian and Guinean climatic regions (FAO, 1987 *In: OSU*, 2000).

Between 4,000 and 3,000 years ago (2,000 and 1,000 BC), herding became established in southern Kenya and Tanzania. Further spread of herding and

⁴ Trypanotolerant animals are resistant to the trypanosomiasis causing sleeping sickness

⁵ The Fulani communities in the Fouta Djallon Mountains of Guinea became sedentary and more agro-pastoralists than pastoralists. See definitions in Section 1.6.1, Southward Expansion Of Pastoralism And Livestock Into East And Southern Africa

agriculture south of Tanzania was blocked for about 2,000 years, some say due to the extremely successful hunter-gatherer adaptation of the Khoisan-speaking people of southern Africa (Martin & O'Meara, 1995) (see Section 1.6.1, Southward Expansion of Pastoralism and Livestock into East and Southern Africa).

1.1.5 Development of Modern Societies with an Agricultural Base

The last few millennia BC saw many societies based on agriculture rapidly develop in Africa and Eurasia (Martin & O'Meara, 1995). July (1970) places the beginning of the Bantu migration spreading agriculture southward, at the time of Christ (0 AD/CE) or about 2,000 years ago (see Section 1.7, BANTU AFRICA).

Diamond (1997) and Thomson (2003) believe plant geography had a major influence on the movements of people and settling of the African Continent. Both Diamond (1997) and Chrétien (2003) show how the Bantu development of sophisticated sedentary agriculture freed up a portion of the society to become involved in non-food producing activities such as the military, commercial and artisanal fields. This development enabled the evolution of clan driven societies into territorial expanding kingdoms and monarchies. Summer-rainfall crops, all coming from north of the equator, permitted the development of surplus food that could support armies. Vande weghe (2004) also believes that crops from the Americas (see Table 1.1) played a major role in increasing food production and allowing populations to grow. From 1550 AD, the Portuguese played a major role in the introduction of these foods. South of the equator, groups like the Pygmies and Bushmen remained hunters and gatherers without such cultivars.

The Xhosa made up the most advanced southern movement of Bantu coming out of Central Africa: They were well established near the bottom of South Africa by

the 18th century AD, but were forced to stop at the Fish River, Eastern Cape Province, because they had only summer-rainfall crops (e.g., sorghum, millet and yams from Central/West Africa and bananas from Asia, among others) (Diamond, 1997; Thomson, 2003). The deserts of the Karoo and Namib did not allow the introduction of traditional agriculture, eventually becoming a safe haven for the Bushmen hunter-gatherers. The Afrikaners (Boers), descendants of Dutch/Huguenot immigrants, who arrived in Capetown, South Africa from 1652 AD, brought with them Mediterranean winter rainfall crops such as wheat and barley, adapted to the temperate climate area (Diamond, 1997; Thomson, 2003).

1.1.6 Arrival of Iron Technology in Africa

Iron smelting technology spread rapidly throughout the Near East, Mediterranean, Europe, entering North Africa through Phoenician traders by 2,800 years ago (eighth century BC) and West Africa by 2,300 and 2,400 (third to fourth centuries BC). Smith (1992) indicates that copper smelting was established in the Sahel between 4,100 and 3,600 years ago (2,100 and 1,600 BC), while iron working was well established in Niger by 2,500 years ago (500 BC). Diamond (1997) places the arrival of iron smelting in Sub-Saharan Africa at 1,000 BC, very close to the dates for arrival of Near Eastern techniques in Carthage on the North African Coast. July (1970) places Africa's first indigenous iron industry at around 2,600 years ago (600 BC) with the Kingdom of Kush on the Nile River, centered 242 km (150 mi.) north of what is now Khartoum. By 2,600 years ago (sixth century BC), iron technology associated with a pottery called *Urewe Ware* was found in the inter-lacustrine area of East Africa possibly coming up the Nile from the iron-making center in Meroe of the Kingdom of Kush (Martin & O'Meara, 1995). Schmidt (1974 *In: Kjekshus*, 1977) indicates that iron works dating back to 2,500 years ago (500 BC) were found in the West Lakes Region (Bukoba/Karagwe) of Tanzania. Nilotic speakers are believed to have brought iron technology into the

highlands of East Africa during the first millennium AD (Martin & O'Meara, 1995). By the fourth century AD, a full-scale Iron-Age culture existed between the Zambezi and Limpopo Rivers (July, 1970).

This technology moved rapidly southward with the Bantu migrations out of western Cameroon and eastern Nigeria, which will be described below (July, 1970). Vande weghe (2004) places the appearance of iron smelting in Niger at around 3,000 years ago (1,000 BC), in the Great Lakes Region about 2,600 to 2,500 years (600 to 500 BC) ago, in Gabon's Ogooué Valley at around 2,400 to 2,300 years ago (400 to 300 BC) and in Gabon's estuarine area by 1,900 years ago (2nd century AD). He also states that this technology arrived in the lower Congo by the second century AD, in the Batéké Plateau (near modern-day Kinshasa, DRC) by the third century AD, in the woodlands of Katanga (today's DRC) between second to fourth century AD and in the Transvaal (today's Gauteng, Limpopo, Mpumalanga and Northwest Provinces, South Africa) by the 13th century AD (Based upon estimates for arrival of the Bantu in South Africa, 14th century AD might be more accurate). On the other hand Diamond (1997) argues that copper smelting had been going on in the West African Sahara and Sahel since 4,000 years ago (2,000 BC), and that this technology may in fact have developed independent of its introduction from the Mediterranean given the fact that the blacksmithing techniques were significantly different between the two areas. July (1970) supports the theory believing that iron making developed on its own in West Africa independent of that in the Nile Basin, or was possibly introduced around 2,300 years ago (300 BC).

1.2 MAN THE HUNTER

It is humans' evolution into hunters, super predators, which is believed to have had much to do with the development of who we are and set us apart from all

other animals. Humans are the only primates who became dependent on meat for survival (Ardry, 1976). Hunting impacted on humans psychologically, socially and territorially (Ardry, 1966). This included them developing a much increased intelligence with a long-developing brain that did not reach its full capacity until the age of 23 years compared to chimpanzees, whose brain growth is completed at 12 months after birth. Furthermore, humans developed the ability to run on their feet without the use of their hands, freeing the latter for other activities such as the use of weapons. A longer childhood enabled them to learn at a much higher level than any animal before. Cooperative hunting required the development of speech and facial expressions to improve communication (Morris, 1971). Being small and vulnerable, men with their primitive tools hunted large meat-rendering but dangerous game in bands to increase the likelihood of success, “winning” in modern-day terms, while fending off other predators that saw them as a meal (Ardry, 1966). Because, the young took so long to develop, man the hunter had to develop a home base and range (territory), much different than the primates before him. Labor became sexually divided, with the women caring for the young and the hearth, while man the hunter ranged widely in all male parties in search of food (Morris, 1971; Ardry, 1976). This eventually resulted in humans developing territories in which they lived, while controlling access to natural resources within the territory necessary for the band’s/clan’s survival (Ardry, 1966; 1976). Adult human males, differed from their vegetarian primate brothers in learning to share food, which might be considered normal carnivore behavior (Ardry, 1966). The “cultural acquisition” of sharing enabled humans to survive the open savannas.⁶

⁶ As opposed to humans, the chimpanzees are known to periodically hunt in bands, more for fun than for food. Unlike man the spoils go to the individual making the kill, not to the group. The savanna baboon hunts only seasonally when gazelle fawns are dropped (Ardry, 1976). Ardry (1976) hypothesized that the practice of hunting by chimpanzees is a relic of the past that is no longer needed in a forest environment where they are currently found. This dates back to the time when humans and chimpanzees had a common ancestor that developed in a savanna environment. Later, humans moved out onto the plains to become primarily meat eaters, while chimpanzees returned to the forest and remained omnivores thriving primarily on fruit, shoots, buds, a few leaves, insects and birds’ eggs.

Through never completely perfected, another aspect of human evolution was the forming of long-term relationships. The prolonged period of adolescence also resulted in a major change in primate socio-sexual behavior through the development of pair-bonding, in which men and women fell in love and remained faithful to each other even when separated for extended periods of time. The woman was sure of the man's support devoting herself to maternal duties, while men could devote time to hunting without the need to fight over females. The young received maximum care and attention (Morris, 1971).

Mutual cooperation, the *noyau* (nucleus) resulted in primitive evolutionary steps towards a society that was characterized by mutual aid and interdependence of the group. This eventually also extended to the biological nation in defense of a social territory. Primitive hunting bands merged into clans with combined territories, then into tribes, confederations and finally modern nation states, in which a single unified territory commanded allegiance, sacrifice and amity of all social partners (Ardry, 1966)

In modern, Western, urbanized man, this instinctual urge to hunt has not been eliminated, even when there is no economic or survival incentive. Big game hunting, fox-hunting, coursing, falconry, bird shooting, fishing and hunting-play among children are contemporary manifestations of the hunting urge. With the advent of the computer, some of the hottest selling software games among adults and children have been simulated hunting games. It is not just about killing, but also about the chase, being “*sporting*” and giving the animal a fair chance to escape. The hunt is a gamble (Morris, 1971), a risk of coming home empty handed, being killed or claiming victory through the taking of prey. In modern-days, this victory is relieved by hanging the artful taxidermy trophy on the wall. Morris (1971) believes that the urge to hunt and gamble is strongest in the lower and upper classes. The middleclass overcomes the hunting urge through their

work, by getting a new customer, making a “*killing*” on a big sale or winning a court case. The lower classes’ work, on the other hand, is boring and routine with limited challenges that cannot replace the uncertainty and thrill of the hunt. In terms of the idle rich, who have been born into or have achieved economic independence, hunting becomes for many their major challenge in life, a demonstration of their manliness and success among their peers. Then there are those, rich, poor and middleclass who are born with a strong hunting urge, a flame that cannot be extinguished. As opposed to hunting for the thrill of it, in many places in rural Africa today, where people are closely tied to living off the natural resource base as a means of survival, there is no sense of “fair chase”, or “sport”, only of survival. One might compare this to the attitudes of American pioneers or Boer trekkers, where wildlife served as a tool of conquest and survival. The conflict between Western “sport hunters” and “traditional hunters” in their identification with wildlife will be brought out more in Chapter 3.

Thus, emerging out of the Pliocene Epoch, for at least 2.5 million years (3 million years in Leakey, Hay, Curtis, Drake, Kakes & White, 1976 *In:* Blankenship, Parker & Ovortrup, 1990), *Homo habilis*, man the hunter honed his skills and developed into a social being. It is not until about 5-10,000 years ago that humans began entering into agriculture as an alternative to hunting, and even then, hunting was a supplement to that which is grown on the land and/or taken from domesticated livestock. Hunting both as a means of survival and as an urge that must be fulfilled is still a strong part of man and his character as we enter into the 21st century AD

Until the middle of the 19th century AD, for a variety of reasons, which will be highlighted, Africans lived from and managed their natural resources (see Chapter 2). Wildlife and the access to other natural resources were tied to their religion, ancestor worship, territory and ultimately to their survival. Today, Africa’s

human populations appear out of balance with their natural systems and in many cases out of touch with these resources – alienated from them, seemingly mining them for short-term gains. What lies behind this? Why is Sub-Saharan Africa where it is today? Why has man the hunter become man the poacher in Africa and what, if anything, can the subcontinent do to address these issues? Forthcoming chapters look into these issues but in order to address them effectively, it must be remembered that modern man is as much a hunter in the 21st century AD as he was 12,000 years ago; some hunt for sport, others for survival and cultural reasons, and others “hunt successfully” on the stock market. Ultimately, man the hunter is here to stay and will not disappear.

The question that must be asked is “Will Sub-Saharan Africa’s mega-fauna be able to survive man in the 21st century AD? Is the primeval urge of the strong overpowering the weak make sense in the 21st century AD when we have become a global society, especially when nations take on this predatory behavior in their quest to control access over resources”? Do there always have to be winners and losers as in the past, where man the hunter or conquering state dominated others, where rich people and powerful countries took advantage of the others? What are the threats to the rich when the poor of the world, with the aid of modern communication, understand more than ever this exploitation, and more than ever appear to be resisting? Can man the hunter’s character allow win-win relationships for everyone just as in the past when he shared meat from the kill? Can humankind behave as a “Global Village”, where poverty can be significantly reduced? If not, what does this imply for Sub-Saharan Africa, its people, and “their” wildlife that the West seems to value so much? Just as importantly, what does this imply for Western civilization as we know it today? While Africa and other developing regions were in the past safely separated by the chasm of oceans, their future and ability to modernize may very well determine not only their

survival but also that of the Western World. These issues are discussed throughout the book.

1.3 CO-EVOLUTION OF HUMANS AND WILDLIFE IN SUB-SAHARAN AFRICA

“Co-evolution is defined as reciprocal selective pressures that operate to make the evolution of one taxon partially dependent on the evolution of another. This process often involves multiple species exploiting shared limiting resources. In classic co-evolutionary models, populations of sympatric species are seen to diverge in one or more morphological, ecological, or behavioral traits to effect more even partitioning of resources and reduce levels of interspecific competition. Character displacement and resource partitioning are thought to be central not only to how species coexist on limited resources, but also to how species invade new resource niches. Hominid invasion of the predatory guild would have brought them into contact with a range of new selective pressures including competition with a number of large-bodied predators” (Brantingham, 1998).

1.3.1 Co-Evolution of Man and Wildlife in Sub-Saharan Africa

A major difference between wildlife in Africa and all other continents is believed to be that wildlife in Africa co-evolved and thrived with man until recent times (the last 200-300 years).

“Archaeological and other studies have shown long-term and widespread associations between hominids and other large-bodied predators in past ecological communities. Throughout hominid evolution there appears to have been a consistent overlap both in the use of space and foraging strategies employed by hominids and large-bodied predators. Such hominid-carnivore associations are apparent in Plio-Pleistocene East and Southern Africa. Hominid-carnivore co-evolution may have been integral to the evolution of a variety of unique human traits such as lithic (man’s use of stone as a cultural tool), large brains, and complex social and foraging group organization” (Brantingham, 1998).

1.3.2 Man and the Extinction of Pleistocene Mega-fauna

“The demise of the Pleistocene mega-fauna (about 10,000 years ago) has perplexed scientists for many years. Climatic change during the last major deglaciation period, which would have caused environmental stress for the ‘ice age’ fauna, has commonly been advanced as the driving force behind the Pleistocene extinctions (Martin, 1986 & Grayson, 1987; 1991 all *In:* Burkhardt, 1995). However, certain features of the extinction are not well explained by the climatic theory. Differential timing of the extinction between continents and the apparent lack of effects on small fauna and flora are difficult to explain under the climatic theory. Equally troublesome are some of the most recent interpretations of past climatic fluctuations which suggest that the Pleistocene mega-fauna survived several early periods of glacial and interglacial climatic pulses, which were more severe than that of 10,000 years ago” (Grayson, 1991 *In:* Burkhardt, 1995).

Similar arguments are made by Leakey and Lewin (1995), who present several possibilities for Pleistocene extinctions and conclude that a number of factors may have caused them, with humans certainly being a primary “agent of extinction”. This leaves the subject open for more debate.

It is now believed that by the time humans arrived in North America and Asia at the end of the Pleistocene, some 12,000 years ago, wildlife had already evolved considerably. The fossil record indicates that for several million years, as in Africa, the North American continent supported a wealth of large ungulates, which only recently, 10,500-7,000 years ago, disappeared. There is increased evidence that these Pleistocene extinctions in North America (Burkhardt, 1995), Asia, the Pacific and Madagascar are not adequately explained by climatic shifts (e.g., the Ice Age).

“Just as the fossil record reveals the co-evolution of the Pleistocene flora and fauna and the existence of these widespread natural herbivores on each continent, the fossils also record the demise of

the mega-fauna” (Flehardt & Hulett, 1977; Martin, 1986; Owen-Smith, 1987; Grayson, 1991 all *In: Burkhardt, 1995*).

Historically, there have been five global species extinction events in the history of the earth, the last being 65 million years ago, marking the end of the dinosaur (Leakey and Lewin, 1995):

1. End of Ordovician, 440 million years ago;
2. Late Devonian, 365 million years ago;
3. End of Permian, 225 million years ago;
4. End of Triassic, 210 million years ago; and
5. End of Cretaceous, 65 million years ago.

One characteristic common to each of these events is a fall in sea level or marine regression, which could have occurred for any number of reasons, including polar glaciation. One theory has it that the exposure of organic mud previously buried on the sea floor resulted in massive oxidation and a drop in atmospheric oxygen levels by half of what they are today, which in turn impacted on terrestrial vertebrates. However, marine regression is not always associated with mass extinctions, implying that other factors must also have come into play. For instance, at the end of the Permian, there was a sudden rise in the sea level, resulting in low oxygenated water; the mass extinctions on land and in the sea at the time are hypothesized to be from suffocation. At the end of the Cretaceous, dust from an asteroid colliding with the earth, possibly in the Yucatan Peninsula of Mexico, could have been responsible for the permanent darkness that reigned, devastating plant life on land and in the sea, as well as associated animal life dependent on plants for food and possibly oxygen. Some say that this served as a *coup de grace*, along with marine regression, to the already outlived dinosaurs (140 million years of domination) and marine ammonoids (nautilus-like shelled invertebrates that had existed for 330 million years). The extinction of the

dinosaur resulted in mammals becoming the dominant land vertebrate. Some hypothesize that extinction bursts, including the “Big 5 Extinctions” occurred at intervals of about 26 million years and that they can all be tied to extraterrestrial bombardment by asteroids and comets (Leakey & Lewin, 1995).

The world is now considered to be in the sixth event, with three major waves of extinction having been identified (Wilson, 1992 *In:* Anderson, 2001). More recently, the theory that the Pleistocene extinctions were primarily driven by human predation has been gaining scientific proponents (Fleharty & Hulett, 1977; Denevan, 1992; Martin, 1970; 1986; 1990; Diamond, 1992; Wilson, 1992; Alcock, 1993; Burney, 1993; Owen-Smith, 1987 all *In:* Burkhardt, 1995). Only on the continent of Africa did the co-evolution of man and the mega-fauna over millions of years provide wildlife “time to learn a healthy fear of man and with it a healthy avoidance of hunters” (Diamond, 2005).

This new predator, man the hunter, populated the new lands and began to dramatically affect the mega-fauna. An interesting aspect of this extinction theory is that the chronology of Pleistocene extinctions on each of the world continents and major islands occurred shortly after the arrival of humans (Martin, 1990; Steadman, 1995 all *In:* Burkhardt, 1995):

- The first wave of extinction took place when humans moved out of Africa on foot and into Europe and Asia from 100,000 – 30,000 years ago. The quantification of species extinction is still to be measured.
- The second wave of extinction occurred when humans moved out of Asia into North and South America by foot, as well as to the Pacific, Australasia and Madagascar by raft from 30,000 to 1,000 years ago.
- The third, and most contemporary, wave of extinction was caused by colonists exiting an over-crowded Europe on sailing ships about 1500 –

1840 AD and again by rail, steamship, motorcar and plane from 1840 – 2000 AD in search of a better life. This has resulted in the wholesale removal and/or modification of habitat, continuing today and compounded by the global population explosion. In the case of Africa it is also linked to poverty, subsistence lifestyles and centralization of land/resource tenure that are discussed in this book.

1.3.3 North America

The Paleo-Indians (Clovis people) arrived at the end of the Pleistocene retreat of continental ice sheets when they crossed the Bering Strait into Alaska, reaching the Gulf of Mexico 11,150 years ago and South America 10,500 years ago. In 1,000 years, the population exploded to several million people. The mega-fauna were far more diverse than that of contemporary Africa, but by about 10,500 years, many species had been hunted to total extinction (Wilson, 1992; Burkhardt, 1995; Leakey & Lewin, 1995 all *In:* Anderson, 2001).

In western North America, the radiocarbon dates of most common genera found in the fossil record indicate that the majority of large herbivores and their associated predators became extinct between 12,000 and 10,000 years ago. This massive extinction over an extremely short period of time removed 70-73% of the Pleistocene mega-fauna in North America (Wilson, 1992; Leakey & Lewin, 1995 both *In:* Anderson, 2001; Martin, 1986 *In:* Burkhardt, 1995).

North America lost 33 of 45 genera of large mammals during this late Pleistocene extinction (Martin, 1986; 1990 *In:* Burkhardt, 1995), some sources estimating extinction at 57 large mammal species (Wilson, 1992 *In:* Anderson, 2001; Leakey & Lewin, 1995). This included the proboscides: early elephant and mastodons and wooly mammoths. Other species that became extinct were glyptodonts/armadillos,

giant sloths, horses, camels, saber-tooth tigers, lions and giant bears (Wilson, 1992; Leakey & Lewin, 1995 both *In:* Anderson, 2001). It is noteworthy that very few small mammals became extinct in North or South America (Wilson, 1992 *In:* Anderson, 2001; Burkhardt, 1995; Leakey & Lewin, 1995). This implies that small mammals had little value to man as a source of food, clothing, shelter or utensils.

From 7,000 years ago to the present, the poor remnants of the Pleistocene mega-fauna have and still include the bison, elk, moose, deer, pronghorn, and bighorn sheep and mountain goats. The extinction by 10,000 years ago of most large herbivores and predators left the natural rangeland-grazing ecosystem, which had existed for several million years, with many vacant niches for large herbivores. To date, neither evolutionary substitution (for which there has been far too little time) nor immigration has filled the empty niches in this natural herbivory (Martin, 1970 *In:* Burkhardt, 1995). Leakey and Lewin (1995) argue that many species of the American mega-fauna that did survive were themselves immigrants across the same land bridge from Asia and had co-evolved with humans for several million years, acquiring wariness and instincts to avoid man the hunter. Others such as the caribou, bison and antelope were unpredictable in their movements, while the moose, spectacled bear and tapir lived in heavy cover, which made detection more difficult. These were only a few of the large mammal species, which existed before the Pleistocene extinctions took place and managed to survive.

“The unrecognized implications of the Pleistocene extinctions on current efforts to comprehend our western ecosystems are tremendous. Underlying nearly all aspects of land management is the assumption that the fauna and flora of North America at the time of European contact was in a pristine natural state of balance. Largely unaware of the fossil record, many ecologists, range scientists, land managers and environmentalists have assumed that this so called pristine balance was the end product of millions of years of co-evolution of plants and animals. The concepts of

climax pristine and natural have pervaded all facets of land management and ecology in the U.S.

When the system is in balance, i.e. all the available niches occupied, extinctions and evolution of new forms occur somewhat equally. The late Pleistocene extinction far exceeded replacement and it affected only the larger fauna...Immigration or ecological substitution has not yet replaced what was lost. This hardly appears to have been a common evolutionary event" (Burkhardt, 1995).

Eventually, the relationship between the American Indians reached a balance and resulted in their co-existing with the remaining wildlife until the arrival of the Europeans.

The bison was one of the few really large herbivores to survive the Pleistocene extinctions and vast herds of these animals roamed the American prairies at the time of first European contact (Roe, 1970 *In:* Burkhardt, 1995). It is ironic that within slightly less than 400 years after Columbus landed in the western hemisphere, Europeans all but hunted the North American bison to extinction (Burkhardt, 1995). In less than 300 years, the American pioneers extirpated much of North America's remaining wildlife (see Chapter 3), which resulted in the imposition of conservation laws similar to those in Africa. As will be discussed in Chapter 3, in both North America and Africa, it was the European and not the indigenous people who hunted wildlife to extinction and/or near extinction.

1.3.4 Rest of the World

Extinctions, attributed to human beings and their invasion, occurred on other continents (Wilson, 1992; Leakey & Lewin, 1995 both *In:* Anderson (2001)):

- Australia lost 86% of its mega-fauna 30,000 years ago with the extinction of 50 species and only 4 species surviving, all kangaroos.

- New Zealand, 1,000 years ago, lost 100% of the mega-fauna and 50% of all birds, including all large and flightless species.
- South America lost 80% of its mammal genera 10,500 years ago and a similar percentage of its largest birds.
- Pacific Islands lost more than 50% of their terrestrial bird species between 3,000 and 1,500 years ago.
- Madagascar was invaded 1,500 years ago, which resulted in the total extinction of mega-fauna within centuries – all endemic species, seven of 17 genera of lemurs, all six to 12 species of elephant bird, pygmy hippo, an aardvark and two huge land tortoises.

Leakey and Lewin (1995) believe that habitat loss resulting from deforestation and the introduction of the rat, both of which are tied to the invasion of the island by humans (the Maoris), as well as hunting, contributed to the extinction of species in New Zealand.

1.3.5 Africa's Mega-fauna and the Arrival of Europeans

This is discussed in more detail in Chapter 3. In Africa, whereas indigenous human occupation through co-evolution had only touched lightly on and had not greatly disturbed relationships within the community of plants and animals, the European arrival, beginning in the 1500s AD, brought decimation in its wake. In South Africa, this resulted in the extinction of a number species, including the bluebuck or blaauwbok (*Hippotragus leucophaeus*) and the quagga (*Equus quagga quagga*), or virtual elimination of the bontebok (*Damaliscus p. pygarus*), the blesbok (*Damaliscus p. albifrons*), the black wildebeest (white-tailed gnu) (*Connochaetes gnou*), Cape Mountain Zebra (*Equus zebra*) and the elephant (*Loxodonta africana*).

Africa's human population explosion of the 21st century AD might be considered a fourth “*Wave of Extinction*” in which the significant reduction in wars and disease because of European colonization has resulted in a level of human pressure on Africa's wildlife never seen before. This has indirectly been due to the destruction of habitat and directly to species extinction/reduction. Stemming the wave of habitat destruction in the 21st century AD, by addressing resource/land tenure and by alleviating human population pressures on Africa's natural systems, will be key to the future survival of the subcontinent's mega-fauna and even human society. Richard Leakey leaves little doubt about his concern for the impacts of modern man on natural systems and the extinction of species in the 21st century AD, “I believe we face a crisis – one of our own making – and if we fail to negotiate it with vision, we will lay a curse of unimaginable magnitude on future generations” (Richard Leakey In: Leaky & Lewin, 1995). Today's Africans, the majority living subsistence lifestyles, can be considered as being out of balance with nature. This argument is a recurring theme throughout the book, as well as the presentation of possible “Ways Forward” in the final chapter.

1.4 WEST AFRICAN KINGDOMS AND EMPIRES

“...there was no interruption of African history. It is evident that, if starting from Nubia and Egypt, we had followed a continental geographical direction, such as Nubia-Gulf of Benin, Nubia-Congo, Nubia-Mozambique, the course of African history would still have appeared uninterrupted. This is the perspective in which the African past should be viewed...Egyptology will stand on solid ground only when it unequivocally officially recognizes its Negro-African foundation” Cheikh Anta Diop (1974).

The well-known Senegalese historian, physicist and philosopher, Diop (1974) provides substantial but controversial evidence that early civilization as known to humankind began in what is now Lower Egypt/Ethiopia/Sudan. Diop (1974) believes this civilization to have been black in origin, gradually interbreeding with

other races, especially whites as the region was invaded by outsiders.⁷ This black civilization is believed to have made major contributions to the arts, religions, agriculture, social organization, medicine, writing and architecture gradually spreading to Europe and Asia. Diop (1974) also traces many West and Central African ethnicities such as the Wolof, Serer, Fulani/Peul, Toucouleur, Fang, Yoruba and Bamum, as originating from the Nile Basin. This is based on morphological, biochemical (e.g., melanin), linguistic, cultural (e.g., matriarchal aspects of societies, kings, circumcision), historical (e.g., Greek and European historians, logs of early European navigators/explorers, Arab and Egyptian translations, Biblical and Koranic writings), archeological, architectural, artistic and religious (e.g., similar gods, totems, ancestor worship) information and ties. Similarly, Schmidt (1998) places the origin of the Bangando, today living in the forests of Southeastern Cameroon, as Sudan in the region of the Nile. The ancient empires of Ghana, Mali, Gao, Yatenga/Mossi and the kingdoms of Djolof and Cayor (both in Senegal) can be traced back to having Egypto⁸-Nubian⁹ roots (Diop, 1974). Diop (1974) hypothesizes that the harshness of the European climate gave Europe superiority over Africa, since this encouraged conquest, accumulation (materialism) and continued technical progress as survival mechanisms. This superiority and the need for slaves to fuel the economies of the New World resulted in a falsification of African history and the black personality that was depicted as half-animal, “a piece of merchandise” (Diop, 1974). Though

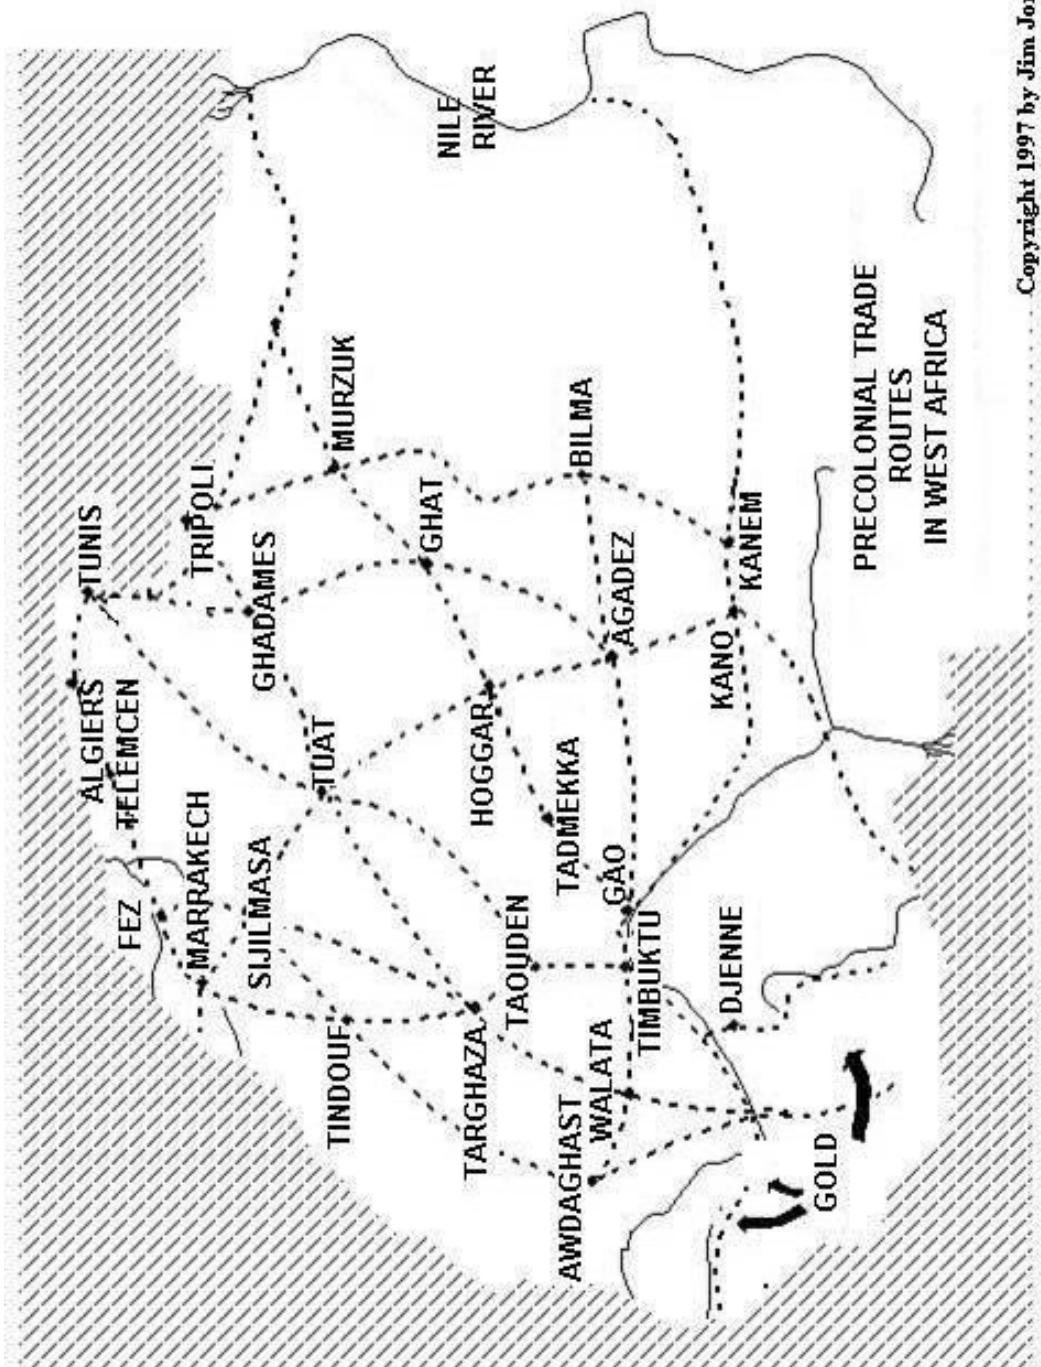

⁷ The Hyksos (Scythians) invaded the region around 1720 BC, after which there was an invasion by Libyans in 1229 BC, which was, however repelled. The Assyrians captured part of Egypt in 671 BC and were followed by the Persians who also invaded Egypt in 525 BC. A number of other invasions took place afterwards and were carried out by the Macedonians under Alexander in 333 BC, the Romans under Julius Cesar in 50 BC, the Arabs in the seventh century AD, the Turks in the 16th Century AD, the French with Napoleon (1798-1801 AD) and the English invasion of 1882 AD (Diop, 1974).

⁸ Depending on various historical interpretations, the Egyptian culture/civilization can be traced from 17,000 BC to about 3,200 BC when Menes unified Upper and Lower Egypt into a kingdom. By then the calendar (4245 BC) and the transmission from Meroitic Sudan to Egypt (4000 BC) of the 12 hieroglyphs that were the first embryonic alphabet had taken place (Diop, 1974).

⁹ Nubia refers to Sudan or the Land of Kush south of Egypt, which was called “land of the gods” by the Egyptians (Diop, 1974).

Diop's theories seem highly controversial to many Westerners and Egyptologists, often European, who prefer that the origin of modern civilization be attributed to whites, he has a wide following on the African continent and in certain academic circles.

The single most important development in the history of northwestern Africa was the use of the camel as a transport vehicle. In ancient times, the Egyptians and Carthaginians engaged in just a trickle of commercial trade with West Africa, even though the region was rich in gold, other precious metals, ivory, and other resources. The reason for this was the imposing barrier of the Sahara, which in Arabic simply means "The Desert". Around 750 AD, under the influence of Islamic peoples, northern and western Africans began to use the camel to transport goods across this forbidding terrain. Camels do several things exceptionally well: they can carry unbelievably heavy loads for impossibly long distances and they can keep their footing on sandy terrain. It was as if someone had invented "sand ships". The effects of camels on West African culture were just as profound as if they were sea-going ships (Hooker, 1996). In essence, the Arab trade caravans enhanced the development of urban communities and the centralization of political power in West African kingdoms that regulated and controlled trade (Martin & O'Meara, 1995). Salt and gold were the driving forces behind the desert trade. Wangara Gold came from two distinct areas: 1) the Lobi area of Upper Volta (Burkina Faso) and 2) the Guinea-Conakry/Mali area between the confluences of the Niger, Senegal and Falémé Rivers, while salt was mined at Taghaza (Targhaza) (see Figure 1.2) (July, 1970).

Figure 1.2: Ancient Saharan caravan trade routes

The most important developments occurred in the Sahel (Figure 1.3) area just south of the Sahara; the Sahel provided southern terminal points with the goods

being shipped across the Sahara. The Sahel is a dry, hot area on the edge of the desert with fertile areas mostly along river floodplains, and grasslands. All of the major North African kingdoms arose in this area: Ghana, Mali, Songhay, and Kanem-Bornu: the Sahelian kingdoms (Hooker, 1996) (Figure 1.1).

Figure 1.3: The Sahel

Historians Brooks (1986; 1993 *In: McCann, 1999*) and Webb (1995 *In: McCann, 1999*) state that West Africa's empires were heavily influenced by historical zones that were not fixed by geographical boundaries but by shifting rainfall boundaries (isohyets) that generate particular types of vegetation and impose specific constraints on human activity (Figure 1.3):

- The 100-200 mm isohyets separate the Sahara desert from the Sahel;
- The 400 mm isohyet form the southern border of the Sahel, where drought tolerant crops like sorghum and millet were cultivated;
- South of the 400 mm isohyet, are the Sudano-Sahelian and Sudanian savanna zones and this is more or less also the northern limit for maize cultivation; and
- The 1000-1,200 mm isohyets define the forested savannas zone and the northern limit of the tsetse fly (vector of human and bovine sleeping sickness/trypanosomiasis) habitat, south of which only the N'Dama cattle are resistant to the tsetse fly (trypanotolerant), as opposed to the more drought tolerant zebu (*Bos indicus*).

These authors also argue that the 1,000 mm isohyet and the tsetse fly provided a protective screen to agricultural societies against horse-raiding people from the north. This zone in West Africa fluctuated as much a 200 km north and south, thereby altering the livestock economy and military advantage. Nash (1969 *In* : Smith, 1992) places the minimum rainfall for survival of the tsetse fly as 500 mm meaning that by 6,500-4,500 years ago (4,500-2,500 BC) the Sahara would have been too dry for the fly.

This fluctuation is related to the Inter-Tropical Convergence Zone (ITCZ) with its bimodal wet and dry seasons, characterizing the African continent as a whole. Variations from year to year and in location depend upon elevation, topography, and global climate anomalies such as El Niño and tropical Atlantic surface circulation. Several years of short or delayed rains constitute drought, historically a common occurrence in much of Sub-Saharan Africa (McCann, 1999).

Webb (1995 *In*: McCann, 1999) argues that shifts in climate/ecology/economy that took place between the 14 and 17 centuries AD brought the desert, savanna and Sahelian peoples into closer contact with each other and produced a new

historical identity that blended the economies and historical traditions of the Arab, Amazigh (Berber) and Mande peoples. It is argued that the growth of Timbuktu from 10,000 people in 1325 AD to a commercial and intellectual center of 30,000 – 50,000 people in 1591 AD to some extent had its development rooted in ecological change. He also argues that a drier period in the 17th century AD allowed for southward military expansion and resulted in a loss of human freedom (slavery) as the desert moved southward and waves of political violence broke onto the savanna, catching black Africans in the undertow.

McCann (1999) argues that the physical environment of the great empire states was not a fixed canvas, but rather a shape-shifting stage that demanded a continuing set of adaptations of economic base and political structure. Africa's Sahelian Zone from Senegal to Eritrea has always been a stage for struggle between climate, water resources and human strategies of political, social and economic organization. Great African empire states from Ghana, Mali and Songhay in the west, Bornu, and Darfur farther east (an area of conflict in 21st century AD; see Chapter 5, Section 5.11.4, Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics and Chapter 13, Section, 13.10.1.6 Oil-scorched earth Sudan), as well as Nubia and Aksum in the Nile Valley all managed to link long-distance trade, urban settlements and sophisticated politics with farm-level successes in food production within arid and semi-arid zones. These achievements were particularly remarkable because they meant overcoming the Sahel's environmental challenges. The decline of civilization in the Niger Valley at the end of the 16th century AD was due to a wider set of factors than an invading army from Morocco or even the impinging desert (McCann, 1999). These factors included (McCann, 1999):

- Decreasing farm productivity;

- The retreat of livestock herds in favor of camel husbandry (under dryer conditions); and
- The loss of population to slavery.

Ecology played a major role in this evolution. McCann (1999) tries to promote the idea that desertification in Africa is attributable to global climatic processes more than local human action, although in his epilogue he admits that changes in human land use and the human population have wrought the most profound transformations of Africa's landscape mosaic, with the population proving consistently cumulative in affecting the look of the land in the late 20th century AD.

The following discussion is not meant to be all inclusive of pre-colonial African civilizations, but demonstrates that vibrant civilizations existed, rich in culture, both written and oral history, strong military forces, lucrative trade, and well developed urban centers, some on par with anything found in Europe at that time. July (1970) explains that every one of the medieval savanna kingdoms described below possessed traditions involving migrations of ruling dynasties from the north and east, these rulers soon becoming absorbed into Negro kingdoms that held the reins of government during the apogee of powerful Sudanic states such as Ghana, Mali and Songhay (Songhai).

The bulk of the savanna population was and is a product of racial intermixing, with villages of completely different tribal and cultural backgrounds peacefully co-existing (e.g., Fulani pastoralists of mixed Caucasian/Negro blood intimately linked to Sudanic communities, grazing during the dry season on farm residue while manure from their livestock helped fertilize the Bantu farmers' soils; (see Chapter 2 for more details). The Sudanic civilization's ability to adopt, absorb and utilize outside influences is best exemplified through the spread of Islam,

which was integrated into animist religions, by the Fulani along trade routes in the 13th century AD. Initially, Islam primarily took hold in cities such as Gao, Kano, Awdogha, Walata, Kumbi Saleh and Timbuktu (Figure 1.2) along the caravan routes, whose commercial activities made them receptive to outside influences, and where the African and Arab world mixed (July, 1970).

Ancient Ghana existed for three centuries, Mali for 400-500 years, and Kanem-Bornu for about 1,000 years. These Sudanic Negro kingdoms' political authorities were structured at two levels (July, 1970):

1. **The Villages** with individual heads of families, a council of elders and the chief quite unaffected by imperial states.
2. The principle of **Lineage and Age Groups** was spread over a number of villages. This meant that people had a fixed status such as rulers, nobility and serfs, carrying out inherited occupational roles such as farmers, merchants, craftsmen, blacksmiths and hunters, or inherited civic functions that changed through successive age grades.

State making occurred when the leader of one of these affiliations succeeded by persuasion or force to impose his authority on a number of independent villages. Rulers depended on maintaining clan relationships that supplied them with troops, tribute, labor and servants. These savanna kingdoms were rarely homogenous culturally or ethnically, with imperial expansion often outrunning the ability to administer or police, nor was there orderly transfer of power through succession (July, 1970). One will observe that the exact dates of key events vary widely with historians.

1.4.1 Ancient Ghana

Ghana was the earliest known kingdom of the Sudan. Control of Wangara gold assured its prosperity (July, 1970). Ancient Ghana's boundaries included most of modern Mali and parts of modern Senegal and Mauritania (Figure 1.1). Modern Ghana, formerly the Gold Coast during the colonial era, was named after this great state of African antiquity. The ancient state of Ghana emerged some time around the seventh century AD. However, its oral records, which list over 144 kings, place its existence some time around the seventh century BC (The Sankofa Project, 1999). McCann (1999) places the duration of the Empire of Ghana from 400 – 1250 AD. The Berbers (Tuareg), a Caucasoid primarily nomadic people formed a new kingdom called Ghana or Awkar in what is now southeastern Mauritania in the fifth century AD. This Berber kingdom would form the model from which all the Sahelian kingdoms would be built. The Tuareg are justly famed as the founders of Timbuktu, which began as a small Tuareg village around 1100 AD (MacDonald, 2002). Timbuktu was conveniently located at the end of the trade route with links to Venice, Genoa and Cairo (July, 1970). However, the Songhay, a Sub-Saharan group, were the primary occupants of Timbuktu as it became a city (MacDonald, 2002). Eventually the Soninke, a Mande-speaking people living in the region bordering the Sahara, dominated the state. They built their capital city, Kumbi Saleh, right on the edge of the Sahara and the city quickly became the most dynamic and important southern terminus of the Saharan trade routes (Hooker, 1996). By the 11th and 12th centuries AD, Ghana had become a great military power. Ghana continually suffered from competition with Awdogha (Figure 1.2) to the west that was controlled by Sanhaja Berbers and competed with Ghana as a major trade route terminus.

A hereditary king called the *Ghana* reigned supreme (Hooker, 1996) over a matrilineal empire, the sister of the King providing the heir to the throne. The

king was assisted by a people's council chosen from the social strata, indicating sophisticated political development (The Sankofa Project, 1999). At the peak of its empire, Ghana's population of several million occupied a territory of about 647,500 km² (250,000 mi²). An army of 200,000, containing about 40,000 archers helped to maintain the king's imperial might (ANON, 2002b)

The king controlled the flow of gold from the south and the traffic of salt from the north (MacDonald, 2002). The gold trade was largely responsible for the development of Ghana into a powerful, centralized kingdom. Gold was traded for salt that came down from the Sahara desert (from Morocco and Algeria) (ANON, 2002a). The Kingdom of Ghana rapidly expanded into an empire conquering local minor states and boasting a mixed economy of extensive agriculture, iron smelting, stonemasonry, carpentry, pottery, goldsmithing, and cloth manufacturing. Trade passed from West Africa east to Egypt and the Middle East, primarily involving gold, salt, copper, and even war captives to be sold as slaves (The Sankofa Project, 1999).

The Kingdom of Ghana never converted to Islam, even though northern Africa had been dominated by the faith since the eighth century AD. The Ghanaian court allowed Muslims to settle in the cities encouraging Muslim specialists to administer the royal court and advise the government (The Sankofa Project, 1999). Islam was mainly in urban areas, while rural areas remained animist. With the collapse of Ghana in the 11th century AD, Islam became a state religion among the Sudanic civilizations, with Songhay cities such as Djenné and Timbuktu having Islamic universities by the 16th century AD (Martin & O'Meara, 1995).

In 1076 AD, a Berber army from Morocco led by religious reformers called *Almoravids* attacked Ghana, declaring a *jihad* (holy war). By 1087 AD, the

empire disintegrated into several smaller states, including Kangaba out of which the Empire of Mali arose (ANON, 2002b). July (1970) places the final collapse of Ghana at 1203 AD, when the Soso chieftancy of Kaniaga's leader Sumanguru Kanté, (Kaniaga was a former vassal state) sacked Kumbi Saleh, the chief mercantile and intellectual center in the Sudan. Merchants moved about 161 km (100 mi.) north to Walata (Figure 1.2) that soon emerged as the major caravan terminus of the region.

1.4.2 Ancient Mali and the Mandingue (Mandinka/Malinké) Empire

Despite the fall of the Ghana Empire and the rise of the Islamic Mali Empire in 1235 AD, control of the gold-salt trade remained the economic lifeline of the region and resulted in the establishment of a second major gold-salt trade route northeast across the Sahara, which passed through Tunis, and Cairo and thereby complimented the traditional western Sudan—Maghreb—Europe trade route. This second route increased Egypt's influence over western Sudan (ANON, 2002c). Once Ghana had been conquered, Sumanguru Kanté moved south along the upper reaches of the Niger River to subdue the Mandinka (Malinké) Negroes occupying fertile farm land near one of the sources of West Africa's gold supply (July, 1970). The Soso leader Sumanguru Kanté did not govern as sole monarch, but ruled a federation of subject states, one of which was Mali that had fallen under Soso control by the first quarter of the 13th century AD (Sankofa Project, 1999). Mali incorporated three subgroups or factions, namely Malinké/Mandingue (Mandinka), Bambara and Diaghanké (Kake, 1983).

1.4.2.1 Sundjata (Sundiata) Keita

The historical founder of Mali was a mystic by the name of Sundjata Keita (Sundiata). He was said to have begun as a royal servant and magician among the

Soso peoples who then ruled the Ghanaian Empire (Sankofa Project, 1999). It is said that Sumanguru Kanté put all the sons of the Mandinka ruler to death except the cripple Sundjata Keita, who was consequently able to obtain local support in the creation of a guerrilla army that defeated and killed Sumanguru Kanté in 1235 AD (July, 1970). It was under Sundjata Keita that the *Donso (Dozo)* warrior hunters developed, who have managed to survive colonialism and independence into the 21st century in much of West Africa (see Chapter 2, Section 2.1.6, Hunting Guilds as a Means of Controlling Access to Wildlife and Chapter 9, Section 9.8.9, *Gestion des Terroirs*, West Africa). Mali became one of the immense states of pre-modern Africa and had a complex governmental structure headed by the king and managed by officials, sub-kings, and bureaucrats. The *griot* became famous as an oral historian, a tradition passed down through generations of Mande bards and which is still common across much of today's West Africa.

The Soso were absorbed, the remnants of Ghana annexed in 1240 AD and control was taken of the Wangara gold (July, 1970). Sundiata ruled Mali from about 1230-1255 AD, expanding Mali's empire west to the Atlantic Ocean, south deep into the forest, east beyond the Niger River, and north to the salt (Taghaza) and copper mines of the Sahara (July, 1970; The Sankofa Project, 1999). At its height, Mali was a confederation of three independent, freely allied states and 12 garrisoned provinces (The Sankofa Project, 1999). It was during this period, in the 13th century AD that Timbuktu began its development as an *entrepôt* for desert caravans (July, 1970).

It is said that while Mandinka princes were Muslim, Sundiata remained an animist with a power base and administration built upon his relationships with clans and lineage groups rooted in a farming economy (July, 1970).

With the death of Sundiata in 1255 AD, additional conquests were made by Wali (1255-1270 AD) and Sabakura (1285-1300 AD) a freed slave of the royal household who seized power. One of these two conquerors first brought Songhai under Mali suzerainty (e.g. as a semi-autonomous vassal state). Sabakura was responsible for the capture of Gao to the east, often attributed to the popular Mansa Musa (July, 1970).

1.4.2.2 Mansa (Kankan) Musa

The Malian king, Mansa (Kankan) Musa (1312-1337 AD) expanded Mali's influence over the Niger city-states of Timbuktu, Gao, and Djenné. Mansa (Kankan) Musa, a devout Muslim, built magnificent mosques throughout Mali (The Sankofa Project, 1999). By then the Mali Empire reached north into the present areas of Mauritania and southern Algeria, and south into the northern Nigerian Hausa states (ANON, 2002b).

In 1324 AD, Mansa (Kankan) Musa made a pilgrimage to Mecca with an entourage of 60,000 people and 80 camels carrying more than two tons of gold to be distributed among the poor. Of the 12,000 servants, 500 carried staffs of pure gold. The saturated gold markets of regions such as Egypt were ruined for months/years after Musa's visit (July, 1970; The Sankofa Project, 1999). In spite of his devotion to Islamic religion and civilization, Musa continued to rely on traditional institutions (clans, lineages) and their animist beliefs for the administration of his realm. Despite the might and glory of Mali's great leaders, the integrity of local chieftaincies was scrupulously observed (July, 1970).

Under Mansa (Kankan) Musa, Timbuktu became one of the major cultural centers not only of Africa but also of the entire world. Vast libraries were built and *madrasas* (Islamic universities) established. Timbuktu became a meeting-place of

the finest poets, scholars and artists of Africa and the Middle East (The Sankofa Project, 1999). Returning from his *hajj*, Musa brought back Muslim scholars, architects, and other skilled men. Students and professors from all over the Muslim world were attracted to this intellectual center (July, 1970; ANON, 2002b).

The days of the charismatic warrior-kings were past. No longer were *mansa* seen as semi-mythical leaders in battle. The *mansa*'s powers had been delegated to him by the will of Allah, to whose all-powerful judgment the *mansa*, along with the lowliest of his subjects, had to submit. The faith of the *Q'uran* and traditional beliefs (animism) were practiced side-by-side, often by the same communities and even by the same individuals, still the case today over much of West Africa. Such a "mixed Islam" became a hallmark of religious experience in West Africa, helping contribute to social and political stability. Unfortunately, throughout the history of the Sudanic regions, such "tolerant" forms of Islam were open targets for the *jihads* (Islamic religious wars) of strict-minded Muslim reformers from North Africa and the Sahara. Islamizing kings were not always regarded with affection by non-Muslim subjects, which is one reason Musa, who was written about in Arabic sources, is conspicuously absent from West African oral traditions, probably because he was seen as a betrayer of ancestral heritage. By 1455 AD, the Mali Empire extended all the way to modern-day Gambia (Kake, 1983)

1.4.2.3 Collapse of an empire

In spite of Sundiata's efforts in the 13th century AD to ensure continuity of the office of *mansa* within the Keita (a Mandingo/Malinke name) line, troubles with succession were latent from the beginning. Sundiata seems to have intended the *mansaship* to pass in fratrilineal order, from brother to brother, not father to son.

Claims of sons, combined with rivalry between and within the two main family lines (descendants of Sundiata and of Manding Bory, a brother of Sundiata's), led to a series of destructive palace intrigues from the late 14th century AD onwards (Rotondo-McCord, 1998a).

Weakened by internal quarrels, Tuareg (Berbers) from the desert challenged Mali's position in the trans-Saharan trade, capturing Timbuktu between 1433 and 1434 AD (July, 1970; Rotondo-McCord, 1998a) and Walata (July, 1970). Brooks (1993 *In: McCann, 1999*) argues that dry conditions forced Tuareg camel pastoralists south.

In 1468 AD, Sunni Ali of the rising Songhay (Songhai) Empire captured Timbuktu and five years later the impregnable town of Djenné (Jenne) (see Figure 1.2) (July, 1970). Mali's collapse as a major Sudanic power was sealed by the rebellion of Songhay under the leadership of the Sunni dynasty, whose 15th century AD scion Sunni Ali would carve a Songhay empire out of many of the lands previously under Mali's control (July, 1970; Rotondo-McCord, 1998a). Still the Empire of Mali was important enough that in 1484 AD Portugal sent a resident ambassador (ANON, 2004). The other great nomads of the savanna belt, the pastoralist Fulani, broke Malian hegemony in the Senegambia region by the early 16th century AD (Rotondo-McCord, 1998a). Mali's power lingered on in the West but was finally snuffed out in the mid-17th century AD with the appearance of the Bambara states of Kaarta and Segu (Segou), changing Mali's 400 years as an empire back to that of a small chieftancy on the upper Niger River (July, 1970).

1.4.3 Songhay (Songhai) Empire

The people of Songhay were farmers and fisherman who lived along the Niger River (July, 1970; The Sankofa Project, 1999), in what is today northwestern Nigeria (July, 1970) converting to Islam around the 1200s AD (The Sankofa Project, 1999). It is said that invaders from the north, possibly refugees from Kush after the fall of Meroe or Berbers established the Za dynasty but were soon absorbed by the local population (July, 1970).

Gao (Figure 1.2) was established well over a thousand years ago (possibly in the 700s AD) on the right or southern bank of the Niger as a trading camp used by Sorko fishermen and hippopotamus hunters. The Sorko camp, on the opposite side of the river from Saharan trade routes, was protected from nomadic raiders, while at the same time tempting these desert nomads to establish more peaceful trading contacts. Berber merchants brought salt from the Sahara to this early Gao in return for grain, textiles, slaves, and other items. The Berber merchants (now Islamized) set up a permanent base on the left or northern bank of the Niger - Gao-Sané - in order to trade even more efficiently with right-bank Gao. By the ninth century AD, Gao was becoming the center of the Za-Songhay state and an important link in the wider trans-Saharan trading network. With the coming of Islam to the Gao court at the turn of the millennium, closer ties were forged between the newly converted Za rulers and the Muslim Berbers on the other (left or northern) side of the river; they even shared a common place of prayer (Rotondo-McCord, 1998b).

A Songhay Kingdom in the region of Gao existed since the 11th century AD, but came under the control of Mali in 1325 AD (The Sankofa Project, 1999) under the reign of Mansa Musa (July, 1970). By the 15th century AD, Songhay had reasserted its independence from a weakened and collapsing Mali and under the

leadership of the Sunnis, Muhammad Da'o and Sulaiman Dama, a number of Bambara groups were absorbed as well as parts of Macina. However, its main imperial thrust began in 1464 AD with Sunni Ali (July, 1970).

1.4.3.1 Sunni (Sonni) Ali

Songhay would not fully eclipse Mali until the reign of the Sunni king, Sunni Ali, who ruled from 1464-1492 AD (The Sankofa Project, 1999). Gao was said to have a population of 60,000 inhabitants (Martin & O'Meara, 1995).

Sunni Ali turned the Kingdom of Gao into the Songhay Empire. Ali based his military on a cavalry and a highly mobile fleet of ships on the Niger River (July, 1970; The Sankofa Project, 1999; Brooks, 1993 *In: McCann, 1999*). He conquered the cities of Timbuktu and Djenné, the major centers of education and trade of the Mali Empire and drove the Berbers from the region (The Sankofa Project, 1999). He also overran the whole Niger country from Djenné (Jenne) to deep into the homeland of the Mossi (today's Burkina Faso) whose independent kingdoms had existed since the middle of the 11th century AD. Similarly, to Sundjata Keita, Sunni Ali created an empire through rapid military conquest and constructed an administrative system based on customary practice, thereby converting military victory into a permanent political force. He divided the empire into provinces and appointed officials, coordinated the traditional cults on behalf of the state and exercised constant pressure on divisive forces such as the Fulani of Macina and the tribes of the Hombori Mountains (in present-day Mali) (July, 1970).

He also refused fully to accept Islam, advancing African traditions (ANON, 2002b). While professing Islam, he persecuted the Muslim scholars of Timbuktu when he felt they challenged his authority as a magician king (animist) at the head

of a traditional hierarchy (July, 1970). The prosperity of cities under the Songhay regime led to the formation of an urban elite with strong ties to both Saharan merchants and Muslim clerics (*ulama*), who developed a theocratic “ideology of protest” seeking to make the state dependent on Muslim law or “*Shari'a/Shariah/Sharia*”. Sunni Ali, a Muslim, was also known as a powerful magician-king, reminiscent of the legendary kings of the Malinke such as Sundiata. He favored a balance of political and religious powers, in which the interests of both Muslim city-dwellers and rural non-Muslims were accommodated. Unwilling to submit to the new “revolutionaries”—the *ulama*—Sunni Ali targeted clerics for exile, prison, or even death. His style of rule, reminiscent of medieval Europe, was destined both to perish with the rise to power of the pro-*ulama* *askiyas* after 1492 AD and to be condemned as pagan and evil in later Muslim histories of the Songhay (Rotondo-McCord, 1998b).

The copper mining town of Takedda, on the eastern trans-Saharan trading route, contributed to the Songhay Empire’s financial growth, while trade along the eastern trans-Saharan route, created during the Mali Empire, also reached its peak (ANON, 2002c).

1.4.3.2 Askia Muhammad Touré

When Sunni Ali died by an accident in 1492 AD, around the same year Christopher Columbus had reached the western hemisphere, his governor of the western Hombori province, charismatic Muhammad Touré (of Songhay and Soninke descent) usurped the throne and established the Askia dynasty (July, 1970; Rotondo-McCord, 1998b). Askia Muhammad Touré’s Songhay dynasty lasted from 1493-1528 AD (The Sankofa Project, 1999). Years of victorious campaigning had led to the development of a well-trained Songhay fighting force in which men of even modest social rank could rise to the top on the basis of

talent and accomplishment. Muhammad Touré (Turé) had considerable backing of the army, and as a pious Muslim was favored by the clerical urban elite of Timbuktu and other cities (Rotondo-McCord, 1998b).

In 1492 AD, when Sunni Ali's son Abu Bakr refused to establish Islam as the religion of the realm, Muhammad Touré and his pro-Muslim followers declared a *jihad* against the enemies of the faith within Songhay. By the spring of 1493 AD the Muslim forces were victorious, and the first of the *askiyas*, Muhammad Touré, became the undisputed ruler of Songhay (Rotondo-McCord, 1998b).

He found the decentralized administration, relying on traditional local authorities and animism, inefficient and impious to Islam. He therefore created a highly centralized state where the *askia* (*askiya*) had the power to appoint ministers and regional administrators, impose taxation and rule over a professional army (July, 1970; The Sankofa Project, 1999; ANON, 2002a). He also encouraged scholarship and learning and used the combination of Islam and commerce to build his kingdom, thereby bringing peace and stability to the region (ANON, 2002a).

After, Muhammad Touré had conquered Mali and Hausaland, his kingdom covered most of West Africa and was larger than all of the European states combined. With literally several thousand cultures under its control, Songhay ranked as one of the largest empires of the time (The Sankofa Project, 1999). During the 16th century A.D, Songhay developed the most complex and centralized constitutional structure ever known to medieval Sudan, governing a vast empire of 1.3 million km² (half a million mi.²) with central government headquartered in Gao. A professional bureaucracy functioned solidly for almost a century (from the accession of Muhammad Touré in 1493 AD to the Moroccan conquest of 1591 AD). This surpasses the Frankish king Charlemagne, whose

attempts to develop a complex administrative system, seven centuries earlier in medieval Europe, had met with no lasting success (Rotondo-McCord, 1998b).

He was also the first to standardize weights, measures, and currency, with the result that culture throughout the Songhay Empire began to homogenize. He replaced traditional Songhay administrators with Muslims in order to Islamize Songhay society and he also appointed Muslim judges, called *qadis*, to run the legal system under Islamic legal principles. These programs of conquest, centralization, and standardization were the most ambitious and far-reaching in Africa at the time. However, the vast majority of the Songhay people, around 97%, followed traditional African religions. Islam continued to be primarily urban based (The Sankofa Project, 1999).

Timbuktu once again became a prosperous commercial city, reaching a population of 100,000 people, to which merchants and traders journeyed from Asia, the Middle East and Europe to buy gold. It also became an intellectual center in the Muslim world. Students from various parts of the world came to Timbuktu's famous University of Sankore to study law and medicine. Medieval Europe sent emissaries to the University of Sankore to witness its excellent libraries with manuscripts and to consult with its learned mathematicians, astronomers, physicians, and jurists (The Sankofa Project, 1999).

1.4.3.3 Collapse of an empire

The king's reliance on Islamic advisors divorced him from his pagan people and the old system of clientelism through clan and lineage, thereby destroying traditional checks and balances without substituting new loyalties. Selecting provincial governors from royal households rather than from among traditional leaders increased the possibility of revolt (July, 1970). Songhay's very size would

lead to its downfall, encompassing more territory than could be controlled (The Sankofa Project, 1999). Muhammad Touré fell from power in 1528 AD, deposed by his son, and followed by 60 years of eight mediocre kings and palace revolutions, the problem of succession never being resolved (July, 1970). After the reign of Askia Duad, (1549-1582 AD) subjects began to revolt. Even Songhay's massive army, said to consist of over 35,000 soldiers, archers and cavalry, could not keep order. The first major region to declare independence was Hausaland (The Sankofa Project, 1999).

To the north, European sea routes were beginning to bypass Morocco as a key link on the trans-Saharan trade route. Therefore, Morocco sought compensation elsewhere. During the 16th century AD, the salt-producing center of Taghaza (Figure 1.2) and other desert oases were periodically attacked by Morocco but never held; the long-term plan being to advance on Songhay and its source of gold. The Songhay felt protected by the barrier of the Sahara Desert (July, 1970). In 1591 AD (July, 1970; The Sankofa Project, 1999), an Andalusian (Spain was at the time under control of the Moors of Morocco), Judar Pasha, led 3,000 Moroccan soldiers across the desert just north of Gao on the Niger River. Although much smaller than the Songhay army, it was made up of European mercenaries with muskets, for which the Songhay bows and arrows were no match. Military defeat was quickly followed by political collapse. Morocco found none of the wealth it desired, though Moroccan soldiers occupied Gao and Timbuktu, ruling the region first as a protectorate, but gradually being absorbed into the local population and creating a politically feeble state. However, this defeat spelled the end of the Songhay Empire, resulting in political disintegration, famine and plague. The once mighty empire was reduced to hundreds of village states with raids and petty warfare becoming the hallmark of the times, while trade suffered and Islamic culture atrophied (July, 1970). In 1612 AD, the cities of Songhay fell into general disarray and one the greatest empires of African

history disappeared from the world stage forever. Since this time, no African state has risen to such prominence and wealth as did mighty Songhay (The Sankofa Project, 1999). Only in the 18th century AD did larger states begin to appear; Macina (Fulani controlled) and the Bambara kingdoms in Kaarta and Segu (July, 1970).

Brooks (1993 *In: McCann, 1999*) argues that a wet period between 1500 AD and 1630 AD helped trans-Saharan trade to flourish and the Songhay Empire to control the trade routes further north than Ghana and Mali. On the downside, these conditions allowed Moroccan forces to conquer Songhay in 1590-91 AD, though they were unable to penetrate further south than the trans-Saharan trade route because of the presence of the tsetse fly. By the 1630s AD, Moroccan sultans, unable to compete in the long run with the European mercantilist powers that had been both rivals and trading partners, had lost almost complete control over Songhay. Africa, both north and south of the Sahara, would increasingly come to suffer the effects of a European economy, which thrived on aggressive expansion as the Middle Ages gave way to the modern era (Rotondo-McCord, 1998b). Serving as a prelude to later European arrivals, the golden age of West African empires was over (ANON, 2002b).

1.4.4 Kanem Bornu and the Hausa Kingdoms

Before the dawn of recorded history, and halfway between the Niger and the Nile, lay a vast landlocked sea, which after centuries of climatic warming and desertification would become Lake Chad. Though much smaller than its prehistoric predecessor, Lake Chad until the last 3 decades of the 20th century remained one of the largest inland bodies of water in the world (see Chapter 7, Dams, Section, 7.8.1.5, Waza Logone floodplain, Cameroon). It is also one of the most important sites of human settlement in African history. Lifestyles ranged

from hunting and fishing to pastoralism and agriculture. This diversity of cultures and economies would encourage exchange between societies in the region, but would also mean that competition would intensify as groups followed different paths of social and governmental development. Lake Chad was by virtue of its central Sudanic location a natural connecting point in the vast network of Saharan and Sudanic trade. As with Mali and Songhay, this trade would provide the basis for the growth of powerful centralized states headed by kings, first on the northeast side of the lake (Kanem), and later to the southwest (Bornu) (Rotondo-McCord, 1998c) (Figure 1.1).

1.4.4.1 Kanem Bornu

Ghana, Songhay and Mali had come and gone on the African stage. Near Central Africa, however, another great empire called Kanem arose around 1200 AD (The Sankofa Project, 1999). Between the seventh and ninth centuries AD, people in the Lake Chad area were infiltrated by nomads from the Sahara of whom the Zaghawa (see Chapter 5, Section 5.11.4, Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics) were the chief group, establishing themselves as the ruling aristocracy over a wide area in the savanna around Lake Chad. Kanem was originally a confederation of various ethnic groups (The Sankofa Project, 1999). The Kanuri-speaking state of Kanem took shape somewhere between the ninth century AD (July, 1970) and 12th century (1100 AD) (The Sankofa Project, 1999) under its first king Saif who founded the Saifawa dynasty that lasted 1,000 years (July, 1970).

By the end of the 11th century AD, during the reign of the *mai* (king) Umme Jilne, the royal house adopted Islam, upon which succeeding *mais* developed close ties to Muslim states to the north and east, with pilgrimages to Mecca for both commercial and religious purposes. The strength of Kanem lay in its powerful

army. It had a rigid bureaucracy with a council of nobility and members of the royal household, a network of provincial governors from the king's relatives and an important female element in which the "mai's" first wife, his elder sister and the queen mother had privileged status (July, 1970). The Sankofa Project (1999) identifies the first Kanuri to convert to Islam as Mai Dunama Dibbalemi (1221-1259 AD). Dibbalemi declared *jihad* against surrounding minor states, beginning one of the most dynamic periods of conquest in Africa.

By the 13th century AD, the Kanuri began upon a conquest of their neighbors (The Sankofa Project, 1999). At the height of their empire, the Kanuri controlled territory from Libya to Lake Chad to Hausaland. These were strategic areas since all the commercial traffic through North Africa had to pass through Kanuri territory (Figure 1.1). Because of the military and commercial growth of Kanem, the once nomadic Kanuri eventually turned to a more sedentary way of life (The Sankofa Project, 1999).

In the late 1300s AD, civil strife within Kanuri territory weakened the empire. The Bulala people, who appear to have been vassals of Kanem, pushed the Kanuri out of Kanem in the late 14th century AD. Under Mai Umar bin Idris, the ruling house abandoned the old capital at N'jimi and established itself in Bornu (July, 1970). By the early 1400s AD, Kanuri power shifted from Kanem to Bornu, a Kanuri kingdom south and west of Lake Chad, growing rapidly with the fall of the Songhay (The Sankofa Project, 1999).

For about 100 years, the state remained weak but viable. Towards the end of the 15th century AD, it began to revive into the second Kanuri empire, beginning with Ali Ghaji (1472-1504) and his son Idris Kata-Karmabi (1504-1526 AD), who dealt blows to the Bulala in the east, the kingdom of Jukun in the south and the Hausa in the west (July, 1970).

The Kanuri grew powerful enough to unite the Kingdom of Bornu with Kanem during the reign of Idris Alawma (Alooma) from 1575-1610 AD (The Sankofa Project, 1999) or 1571-1603 AD (July, 1970), who built a Muslim state all the way west into Hausaland in today's northern Nigeria (The Sankofa Project, 1999), and east as far as Darfur (modern-day Sudan along Chad's border) (July, 1970). The Bornu were well known for their chain-mailed cavalry (The Sankofa Project, 1999) and muskets (July, 1970). Idris relied on fiefdoms given out to royalty as a means of maintaining power and control (July, 1970). The economy was agriculturally based using peasants supplemented by slaves. Slaves were an important commodity in the trans-Saharan trade, obtained by raiding to the south; young girls and eunuchs were a specialty brought to North Africa in exchange for Barbary horses, which improved military transport and thus conquest. The Kanem-Bornu Empire's decline began in the 18th century AD, which by the early 19th century AD was under threat from the Fulani who had overrun Hausaland to the west (July, 1970). By 1846, it finally succumbed to the growing power of the Hausa states (The Sankofa Project, 1999).

1.4.4.2 The Hausa Kingdoms

For centuries, the Hausa had occupied an area between Songhay and Kanem-Bornu. Folklore has it that the original ruler, Bayajidda, came from the north and was the son of the king of Baghdad. He slew a serpent harassing the people, married the local queen and his grandsons became kings of the major Hausa states of Gobir and Daura, Katsina and Zazzau (Zaria), Kano, Rano and Biram (July, 1970). July (1970) believes this refers to a series of invasions by outsiders who merged with a Negro people.

“Around 1100 AD hills rich in iron ore dotted the landscape of the region, which would come to be known as Hausaland, between the eastern reaches of the Niger River to the west and Lake Chad in the east. Until the 1100s AD, Hausaland was made up of a number of decentralized agricultural and pastoral villages called hill cults. On these sacred grounds, priests or cult-guardians exercised religious and political power within local societies active in agriculture and trade. Scholars disagree about the precise nature of Hausa growth. Some have argued that the Hausa came from the north (southern Sahara), others from the east (Lake Chad), still others that the Hausa were the indigenous inhabitants of the region. But most generally agree that sometime around 1000 AD, localized cult sites and markets began to evolve into ‘birane,’ (walled towns), ruled by ‘sarkis,’ intent on exploiting the agricultural and mineral wealth of the surrounding countryside. Growing political power of the cities led to ‘Hausaization’ of the lands between the Niger and Lake Chad. Beginning in the late 12th century AD, these villages combined into several kingdoms ruled by partly divine kings. The first of these centralized kingdoms was Daura” (The Sankofa Project, 1999).

A brisk trade across the Sahara to North Africa existed for slaves and kola nuts, the latter being one of the few stimulants permitted to Muslims. Katsina and Kano (Figure 1.2) became the major trading centers. Zaria to the south served as the slave raiding center, Rano as a center of industry and Gobir on the edge of the desert protected Hausaland from raids by nomads from the north (July, 1970).

Islam began taking root in the 1450s AD when the Fulani from the Senegal River began immigrating in large numbers to Hausaland. The Fulani immigration was driven by the desertification of North and Western Africa as they searched for land that could support their herds. Devoutly Muslim, though also retaining a great deal of indigenous beliefs, the Fulani introduced Islam and its books, setting up Islamic schools and learning centers throughout Hausaland (The Sankofa Project, 1999). The degree of commitment to Islam was slight among the general population and the ruling class, but had considerable impacts in cities. In the 15th and 16th centuries, Islamic scholars from Timbuktu visited Hausaland, living and

working in Kano and Katsina (July, 1970). The Hausa Kingdoms were closely allied with Kanem-Bornu to the east, whose military presence brought them peace and stability (The Sankofa Project, 1999). Hausaland was unified by the Fulani conquest of 1807 AD, inspired by the charismatic Sokoto *caliph* Usman dan Fodio (Rotondo-McCord, 1998d), who was exasperated by what he felt was a casual attitude of the Hausa rulers towards Islam. For the first time, this brought the Hausa states under a single ruler (July, 1970). He did not destroy Hausa culture, language or institutions, which remain important features of West African life to the present-day (Rotondo-McCord, 1998d).

1.4.5 Fulani, Toucouleur and Dioula Kingdoms, the Spread of Islam

The Fulani or Peul are a pastoral culture stretching from Senegal to Cameroon. Remnants of their former rich empires remain in places like the *royaume* of the *Lamido* (Sultan) *de* Rey-Bouba near the Bénoué River in the Adamoua (Adamawa) area of Cameroon, which still has a large slave contingent of eunuchs guarding his harem, said to number in the hundreds. This kingdom within the modern state of Cameroon, even in the 21st century AD, covers an area of 36,500 km² encompassing three national parks (Bénoué, Boubandjida and Faro) and surrounding hunting blocks. The power structure is centered around the *Ardo* or *Baaba* (father), also known as *Lamido* with both religious and secular powers due to his divine kinship linked to the Muslim religion. He controls access to all resources in his area, with a court (*faddah*) consisting of the *kaygama* (prime minister), *galdima* (controller of agricultural land), *sarkin sanu* (controller over cattle and grazing) and *alkali* (judge). There are also provincial administrators or emissaries (*nelaabe*, or *doogarii*) followed at the lowest level where each village (*ouro*) has a chief (*djaor'en/jaoro*). These well structured systems of traditional rule still survive over much of Northern Cameroon, co-existing with the Western form of government that has been imposed on them (Mayaka, 2002). This

kingdom is basically sovereign, though agreements exist to allow the national government of Cameroon control over access to wildlife, at least by outsiders (e.g., safari operators, sport hunters and tourists). Access to fish, pasture and agricultural land is still largely controlled by the kingdom.

The collapse of Songhai Empire at the end of the 16th century AD marked the end of an era in western Sudan. Afterwards there was a move away from 200 years of centralized governance. The many smaller states that arose were animist or nominally Islam, such as the Bambara states of Kaarta and Segu, and the Mossi whose empire was in the region of today's Burkina Faso. The Fulani state of Macina was animist until 1776 AD, while as discussed, the Hausa royalty was superficial in its approach to Islam. Only Bornu was a major Muslim state. In the rural areas, from Senegal to Chad, the bulk of the rural people continued to remain animist, Islam being concentrated in urban centers. (July, 1970).

Muslim islands included the network of market villages maintained by the Dyula (Dioula) or Mandinka traders throughout the West African savanna and forests. Kunta Arab nomads from Southern Algeria grazed their cattle along the south banks of the Niger River, influencing the Fulani (July, 1970).

The origin of the Fulani is highly debated. July (1970) describes them as a mixture of Berber and Negro from the Fouta (Futa) Toro along the Senegal River. Kake (1983) provides a number of theories on their origin, from descendants of orthodox Jews, French mercenaries who settled in Upper Egypt, ancient Roman legionaries lost in the desert, pastoralists pushed out of the Nile Valley by the *sécheresse* (drought), to originating from the Sahara. In one way or another, they intermarried and mixed with the Bantu cultures. Their language can be placed in West Africa and is similar to the Serere and Ouolof (Wolof, Djolof) of modern Senegal and Gambia. Kake prefers to describe them as a community of people with similar cultural and linguistic characteristics – an ethnic group rather than a

race. This includes the sedentary Toucouleur (Toucouleur) in the extreme west along the Senegal River, the Fouta Djallon Peul of Guinea-Conakry (sedentary agro-pastoralists) and the Fou Foulbe of Cameroon. In between are the pastoralist such as the Bororoje of Hausaland and the Mbororo (Bororo) of the Adamoua area of Cameroon. It is in the Senegambia area where they prospered prior to creating empires in the 17th and 19th centuries. Diop (1974) believes the Fulani to be the result of mixing between black/white races but implies this occurred in the region of the Nile rather than in West Africa.

As all over West Africa (Western Sudan), the rural Fulani were animists while those in towns adopted Islam. Certain clans of Torodbe Fulani were inspired by the Quadrya (Qadiriyya) Brotherhood brought to Western Sudan by the Kunta Arabs who preached saint worship or *Sufism*, spiritual superiority of Islam, correctness of its law and the need for Islamic states. The Torodbe Fulani had great influence as scholars and clerics, serving as royal advisors and administrators. They disapproved of the prevailing religious laxity over Islam. They believed in *hijra* or flight from the holy land of non-believers and then a *jihad* (holy war) to extend the realm of Islam.

In the 18th century AD, Fulani *jihads* extended outwards from established small-scale Islamic theocracies in the Fouta Toro and Fouta Djallon, their influence being strong even to this day. Fulani from Macina moved into the temperate highlands of the Fouta Djallon (Fouta Jalon), which had been home to animist Mandinka and Susu, taking over through a *jihad* under Ibrahim Mousa, which lasted from 1725 to 1776 AD when Ibrahim Sori established a Muslim government. In 1775 AD, a Muslim theocracy was founded along the Senegal River or Fouta Toro, as Torodbe Fulani under Suliman Bal overthrew animist Fulani Denyanke rulers installing Abd al-Qadir as their leader. While these Islamic states proved unstable, they set a precedent across Western Sudan of

theocratic governments controlled by Muslim scholars and the conversion of the masses to Islam (July, 1970).

1.4.5.1 Fulani takeover of Hausaland

For several centuries, the Fulani lived peacefully in the Hausa states: the Fulani Gida in towns and Bororoje pastoralists in rural areas. The fundamentalist Fulani clerics, however, became increasingly disillusioned with the population's casual approach to Islam and saw themselves as a separate minority. The animist Fulani pastoralists and Hausa farmers, on the other hand, were upset by what they considered to be unjust taxation and corruption by the Hausa government, all of this leading to an unstable situation by the end of the 18th century AD. This resulted in the Sokoto *jihad* led by the religious reformer Usman dan Fodio and the take-over of the Hausa states in a few years: Kebbi in 1805 AD, Zaria in 1806 AD, Kano and Katsina in 1807 AD and Gobir in 1808 AD. Hausaland was consequently divided into two: Gwandu under the administration of Abdullahi, Usman dan Fodio's brother, and Sokoto under Muhammad Bello, the Sultan of Sokoto, Usman's son. Government was introduced along the lines of "*Shari'a/Shariah/Sharia*" (Islamic law) and Sokoto became a center for Islamic scholars (July, 1970).

Eventually, the idea of a Fulani empire eclipsed the idea of a world under Islam, which resulted in needless slaughter and plunder, as well as appointment of Fulani to most government posts. This move alienated the Hausa community. Slaves were a major part of the economy as both an item of exchange and for agricultural labor (July, 1970). In the 1830s AD, the Fulani (Fulb  ) conquered Adamoua (Adamawa) in the northwestern highlands of Cameroon (Giles-Vernick, 2002). Under Fulani rule, private individuals had over 1,000 slaves with provincial governors having many times more (July, 1970). This had ramifications all the

way into the tropical lowland forests of the Sangha River Basin, southeast of the Adamoua (Adamawa) Plateau, as various ethnic groups centralized political control, fled and entered into a permanent state of warfare over resources and slavery (Giles-Vernick, 2002). Eventually, under Bello, the Fulani Empire extended west to Adamawa and south to Yourabaland, an area that by 1837 AD covered much of what is today's northern Nigeria (July, 1970).

The empire remained intact into the beginning of the 20th century AD, when it was taken over by the British. The emirates, which succeeded the Habe Kingdoms of Hausaland, were bound to Sokoto through religious allegiance. While in certain states there was peace, others never completely accepted Fulani rule, with the Hausa language, culture and administration remaining largely intact. The area became an important center of commerce across Africa known for its Kano cloth, leather products such as sandals, kola nuts and slaves (July, 1970).

1.4.5.2 Seku Ahmadu Bari, Macina/Segu

Macina, just upstream from Timbuktu, in the early 19th century AD was similar to Hausaland with a Muslim ruler reigning over mostly animist Fulani pastoralists, Soninke, and Songhai. The Muslim state of Macina was a vassal to the animist Bambara state of Segu and its controlling Dyalo clan was in conflict with the Sangare family. In 1818 AD, a jihad by *Seku* (chief) Ahmadu Bari of the Sangare family created a theocratic state, which included the Muslim centers of Djenné (Jenne) and Timbuktu. Pastoral Fulani and many Bambara were converted to Islam. This state proved to be unstable as there were various Muslim ethnic (e.g., Soninke, Fulani and Arab) rivalries and different views on Islam (e.g., no spirits, drinking or dancing in the extreme). This resulted in a number of civil wars with Muslims fighting each other (July, 1970).

1.4.5.3 El Hadj (Haji) Omar, the armed profit (*prophète armé*)

El Hadj Omar, the son of a Muslim scholar, was a Toucouleur (Tokolor/Fulani) warrior from the Futa Toro of the Senegal River, who had spent time in Mecca and Cairo. While in Mecca, he joined the Tijani brotherhood, becoming both the *moquadem* (delegate) and *Khalifa*, head or supreme commander of this sect in western Sudan (July, 1970; Ducoudray, 1984). A major difference between the Quadrya sect, originating from Algeria, and the Tijani sect was that among the Tijani a commoner had direct access to El Hadj Omar and one's rank depended upon ones skills and courage, and not social origins as among the Quadrya (Ducoudray, 1984). He spent nine years in the Fouta Djallon from about 1838, preparing an army (*zaouiah*) grounded in Tijani doctrine, which operated out of Dinguiray, where he launched his *jihad* in 1852 with black powder muskets obtained by trading with coastal areas (July, 1970; Ducoudray, 1984).

In Dinguiray, he built a fortress with three walls, an outer wall of four meters in height, a second inner wall 50 meters away six meters high with turrets, and a third inner wall guarding the *Donyntutu* or house of the *cheikh* (*sheikh*) (Ducoudray, 1984). He practiced a scorched earth policy if anyone dared resist his army and their conversion to Islam, leveling villages, killing all males and taking women and children hostage as slaves (Ducoudray, 1984). El Hadj Omar took control of Bambara and Mandinka states in the upper Niger and Senegal River Basins, and eventually the Fouta Toro (Senegal River Valley) where the Toucouleur supported him and where he made his first contact with French (*Toubabs/Pink Ears*) commercial interests moving up river from Saint Louis on the coast. The French *commercants* refused to ally themselves with El Hadj Omar by selling him arms. In 1857 at the battle for the French Fort of Medine, upstream from present-day Bakel on the Senegal River (see Chapter 7, Figure 7.2: Dams in

the Senegal River Basin), his army was repulsed. About 600 *talibés* (disciples) were killed by the French using superior canon fire from a gunboat while employing the now celebrated corps of African riflemen, *Tirailleurs Senegalais* under Governor of Senegal, Louis Faidherbe. After this contact with the French, El Hadj Omar made a decision to avoid them at all costs, turning his attention east of the Senegal River (July, 1970; Ducoudray, 1984). He took the Bambara states of Kaarta (Karta) in 1854 AD and the Fulani state of Segu in 1862 AD, arguing that Ahmadu Bari III had allied himself with the infidels of Segu against the true believers (July, 1970). El Hadj Omar's empire stretched from Dinguiray in the Fouta Djallon Mountains of Guinea-Conakry north to the Sahara, west to the Senegal River and east to Timbuktu (Ducoudray, 1984). His Toucouleur Empire was fragile, something which first became apparent in Macina where Qadiriya Muslims revolted against Tijani doctrines. This resulted in his death in 1864 AD. Thereafter the Toucouleur Empire was barely held together by his son Ahmadu, finally coming under control of the French military in 1893. El Hadj Omar's legacy was not an empire, but instead the widespread conversion of West Africans to Islam and the dominance of the Tijani sect (July, 1970), a major force in West Africa even in the 21st century AD.

1.4.5.4 Samouri Touré, Dioula (Dyula) Mandinka

The Dioula Mandinka developed a commercial empire linking the forest and savanna, in the 19th century AD. Small states, such as Kong (Diaghanké ethnic group related to the Mandinka) and Odienne, were established in the southern part of “Western” Sudan. Trade consisted of salt, kola nuts and slaves. Beginning around 1865, Samouri Touré, the son of a *commercant* (merchant), who had been raised as an animist, adopted Islam and unified warring factions in Mandinka country thereby creating a state between the forest and the Toucouleur Empire of El Hadj Omar. This occurred just at the time when French expansionism began

taking place, the latter envisioning a territory from the Atlantic to the Red Sea. Samouri Touré traded with British Freetown for arms and with the Sahara for horses, using slaves as his main barter. In the 1880s AD, while the French were preoccupied with the Toucouleur state established by El Hadj Omar and now under the control of his son Ahmadu, Samouri courted the British to offset the French in his territory of the upper Niger Basin south of Dinguiray in what is today's Guinea-Conakry. He waged a brilliant guerrilla war against the French, which they believed would last two weeks but went on for over seven years and which was based upon leaving behind a scorched earth of villages in ruins, but only after his followers had re-established themselves elsewhere with government and armies intact. In the Mandinka culture, the mother and sister are worshiped almost as a cult. Samouri became a prisoner to save his mother in 1898, dying two years later as an exile in Gabon. Although, he enforced the spread of Islam, he is regarded more as a political than religious figure who tried to create a Mandinka state in the face Of French expansionism (July, 1970). All in all, it can be said that the Mandinka culture has left its mark in the West African countries of the Ivory Coast, Mali, Guinea-Conakry, Senegal, the Gambia, Sierra Leone and Liberia. This is especially observable in terms of art, music, griots (oral historians) and commerce, while the warrior qualities of the past have almost disappeared (see "Dozo", Section 1.4.2.1, Sundjata (Sundiata) Keita and Chapter 2, CHAPTER 2: TRADITIONAL NATURAL RESOURCE UTILIZATION MANAGEMENT and Chapter 9, Section 9.8.9, *Gestion des Terroirs*, West Africa).

1.4.6 The Mossi Empire

The Mossi population numbered 1.5 million people at the beginning of the 20th century AD, thereby representing one of the larger homogenous ethnic groups in West Africa. The population extends from the Inner Delta *Boucle du Niger* well

into modern Burkina Faso. The Mossi people are originally believed to have come from modern Ghana. With their headquarters in what is modern-day Ouagadougou (capital of Burkina Faso), they conquered Timbuktou (Timbuktu) by making use of “masters of the sword and masters of the bow” in the 14th century AD. Askia Mohamed of the Songhai tried to convert the Mossi to Islam but they refused, which led to a *jihad* against them. Like much of West Africa, the cities became Muslim but the majority of the rural people remained animist. By the 15th century AD autonomous Mossi kingdoms appeared. By 1757 AD, Naaba Kango returned after three years in exile from Segou (Segu) and Kong and armed Bambara mercenaries retook control of the Yatenga Kingdom that had sent him into exile. *Naaba* Kango refused to undergo the coronation process, thereby excluding his heirs from the throne. Internal conflict over succession resulted in the French taking control of the kingdom in 1894/95 AD. Neither colonization, when the empire became Upper Volta, nor independence, when its name changed to Burkina Faso would destroy the power of the *Naba*, descendants of the original founder in the 15th century AD. This was due to solidarity at all levels of society, from the military and administration to the culture (Kake, 1983).

The army with its infantry and a horse cavalry using lances and poisoned arrows was renowned throughout western Sudan. Administratively, there were both elected officials and royalty. The entire country was under control of the *Moro Naaba* (king). Under him were provincial chiefs that were semi-independent vassals. Provinces were divided into cantons, each formed by a certain number of villages, each village having a *naaba* or local chief. There was a strict chain of command. The *Moro Naaba* made no decisions without advice from provincial chiefs, while they never gave a command directly to a village, as this was the role of the canton chief. By the end of the 19th century AD, the administrative system began to fall apart due to the fact that the *Moro Naaba* was paralyzed by an entourage of excess such as *soronés*, young pages who surrounded the king,

eunuchs, who had been repeat criminals, an Islamic advisor (*Imam*) and a military advisor/head of the army (*Ten'soba*). Even today, a *Moro Naaba* is still present as a symbol of the Mossi past (Kake, 1983).

1.4.7 Wolof (Djolof) Empire

The Wolof are known today as the traders of West Africa, whose language or commerce follows them. The well known Cheikh Anta Diop places their origins as the upper Nile Basin (Diop, 1974; Kake, 1983). Traditionally, Wolof were found in a territory bordered by the Atlantic Ocean to the west, the Gambia River to the south, the Falémé River to the east and the Senegal River to the north. Their territory was divided into six areas; the Wolo in the north along the Senegal River Valley, Cayor in the West, the Sine and Saloum in the South, Baol and Djolof. The Wolof Empire peaked in the 15th century AD and ended in the 19th century AD with the arrival of the French (Kake, 1983).

The Wolof had a society of elite and castes. The basis of society was the family. The *Dyambour* or *Gore* were the “free people”, including the *Dmoibour* (nobility) and the *Badolo* (proletarian). The captive or slave caste was the *Yoro Dyao/Gnegno*. The system has been described as feudal with royalty, serfs and slaves (Kake, 1983). Additional caste groups included story telling *griots* and *tyeddo* (soldiers) (July, 1970).

The founder of the Wolof Empire was N'Dyadyane N'Dyane, whose empire lasted until the 16th century AD – about 1566 AD, when 5 of the above areas became semi-autonomous vassal states of the Djolof Empire. The Wolo was annexed by the French administrator, Faidherbe, in 1855 (Kake, 1983).

Cayor had a ruler (*damel*) chosen by election who became the master of the soil. Cayor was confronted with 400 years of civil wars and turbulence with neighboring states. In Cayor, *tyeddo* (soldiers) were chosen from royal slavery, giving them power to make and unmake kings. By the middle of the 19th century AD, the animist *tyeddo* were plundering the rural Muslim farmers. The last *damel* was the famous Lat Dior (Kake, 1983), a hero depicted in statues and paintings on his reared horse ready to fight the French. For nearly 25 years, Lat-Dior, the *damel* from 1862-1886, was able to hold off the French, who wished to connect Dakar with Saint Louis to produce groundnuts (peanuts). His ultimate downfall was his conversion to Islam and loss of support by the animist *tyeddo* that allowed the French to defeat him, resulting in his death (July, 1970). The end of traditional rule opened the door for the take over of Senegal by marabouts holy leaders such as the Qadiri *marabout* Chiekh Ahmadou Bamba, founder of the Mouride Brotherhood, and the Tijani *marabout* El Hadji Malick Sy (Hemenway, 1996) (see Chapter 3, Section 3.1.4.1, Francophone colonial Africa, Indirect Rule in Senegal and Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal).

1.4.8 Slave Kingdoms – Dahomey and Ashanti

Pre-colonial empires such as Dahomey and Ashanti (located in what is now Benin and Ghana), where slave ports, respectively, at Ouidah and Elmina flourished, accumulated enormous wealth and power from trade of their fellow Africans. This area of West Africa is also the place of origin of *vodou*, the only indigenous African religion to survive the trans-Atlantic slave trade and remain in practice in the Americas today (Antrim, 2002).

In fact, Europeans often acted as junior partners to African rulers, merchants, and middlemen in the slave trade along the West African coast from the mid-15th century AD onwards. Two factors contributed to this dependency: the coastal geography (rough seas and few good ports) and the diseases of West Africa. European ships anchored well away from shore and depended on skilled African canoe-men whose ability to negotiate across the hazardous stretch of water between the mainland and the waiting ships made the Atlantic trade possible. Malaria, dysentery, yellow fever, and other diseases reduced the few Europeans living and trading along the West African coast to a chronic state of ill health and earned Africa the name of *white man's grave* (Antrim, 2002).

When Europeans first initiated a trading relationship with West Africans in the mid-15th century AD, they encountered well established and highly developed political organizations and competitive regional commercial networks. Europeans relied heavily on the African rulers and mercantile classes to gain access to the commodities they desired. European military technology was not effective enough to allow access by force until the 19th century AD. Therefore, it was African coastal rulers and merchants who controlled the means of coastal and river navigation and to whose advantage the Atlantic trade was conducted (Antrim, 2002).

Domestic and international (e.g., trans-Saharan) slave trade in Western Africa preceded the late 15th-century AD origins of the Atlantic slave trade. Since most West African societies did not recognize private property in land, slaves were one of the only profitable means of production individuals could own. West Africans acquired and expressed wealth in terms of dependent people, whether as kin, clients, or slaves (Antrim, 2002).

Well before the arrival of Europeans, slaves were traded along trans-Saharan caravan routes, linking Sub-Saharan (SSA) Africa with North Africa, the Mediterranean and the Middle East. African rulers and merchants were thus able to tap into pre-existing methods and networks of enslavement. Enslavement was most often a byproduct of local warfare, kidnapping, or the manipulation of religious and judicial institutions. Military, political, and religious authority within West Africa determined who controlled access to the Atlantic slave trade. African elites in the Dahomey and Ashanti empires used this authority by enslaving and selling other Africans to European traders (Antrim, 2002).

1.4.8.1 Ashanti (Asante) Kingdom, modern-day Ghana

Between the 11th and 13th centuries AD, Twi and Akan speaking people emigrated from the drying savanna of the north, mixed with the people of the forests and established small village communities or trading states such as Wassa, Sefwi, Denkyirs, Ashante, Assin and Fante. By the early 15th century AD, trade with the northern caravan trading centers of Djenné, Timbuktu and Hausaland included salt, gold, kola nuts and slaves from the forest. By the end of the 15th century AD, an Atlantic trade developed with the Portuguese; chiefly in exchanging gold for firearms. The area became known as the Gold Coast and by the 17th century AD Dutch, British and Danish interests had established trading posts, while French and Portuguese ships stopped in for trade (July, 1970). The Ashanti (Asante) were the dominant ethnic group of a powerful 19th century AD empire and are today one of Ghana's leading ethnic groups, with more than 2 million members concentrated in south-central Ghana. The political, military, and spiritual foundations of the Ashanti nation date to the first Ashanti king, Osei Tutu who forged the Ashanti Union by bringing together several subgroups from roughly 1670 AD to the 1690s AD. He also built a capital, Kumasi; created the legend of the Golden Stool to legitimize his rule and began celebrating the *Odwira*, or yam

festival, as a symbol of national unity. Over the course of the 18th century AD, the Ashanti conquered most of the surrounding peoples (July, 1970; Antrim, 2002). The King of Kumasi was known as the *asantehene* (head of the Ashanti state), with kings of neighboring states serving as commanders of the national army and forming a council of advisors. Under military exploits, the Ashanti Kingdom rapidly expanded due to the desire of the inland people to break through to the coast and take direct part in the Atlantic trade, as well as the desire for firearms from this trade that would provide authority to the Ashanti economic and political aspirations (July, 1970).

By the early 19th century AD, Ashanti territory covered nearly all of modern Ghana, including the coast, where the Ashanti could trade directly with the British. Their empire stretched 388,500 km² (150,000 mi²). Hereditary chiefs were replaced by a bureaucracy subject to royal appointment and control, while provinces were ruled by proconsuls under royal control. A national treasury was established, which was in charge of tolls and taxes, a state controlled trading company and state controlled mines gave rise to a complex centralized bureaucratic state unusual among West African societies (July, 1970). As the Ashanti people prospered, Ashanti culture flourished. They became famous for gold and brass craftsmanship, woodcarving, furniture, and brightly colored woven cloth, called *kente*. The Ashanti maintained traditional beliefs, with a few converting to Islam and Christianity. During the 19th century AD, the Ashanti fought several wars with the British, who sought to eliminate the slave trade and expand their control in the region. The Ashanti kingdom was finally declared a Crown Colony in 1902 AD following the uprising known as the *Yaa Asantewa* war (Antrim, 2002).

1.4.8.2 Kingdom of Dahomey, modern-day Benin

Dahomey, a pre-colonial West African kingdom, is located in what is now southern Benin (Antrim, 2002). Dahomey had maintained close connections to the city-states of the Yoruba and for a while was a vassal to the Oyo Empire of Yoruba between 1726 -1730 AD. Myth has that the Yoruba origins of its founder were ancient Egypt. It is believed that the Kingdom of Dahomey had its origins in self-defense against slave raiding by a number of coastal states. The Kingdom of Dahomey was unified under King Agaja in the 1720s AD signing a peace accord with the Kingdom of Oyo permitting King Agaja to retain an army and internal self-government under a resented Oyo suzerainty. Independence from a failing Oyo Kingdom was not obtained until 1822 (July, 1970). Dahomey reached the height of its power and prestige during the heyday of the Atlantic slave trade in the 18th and 19th centuries AD (Antrim, 2002) (see Chapter 3, Section 3.1.7.2, Cultural genocide). Slavery was a state monopoly, with the two administrative posts of *mehu* and *yovogan* directing national trade and financing, including trade in slaves (July, 1970). The kingdom was also known for its rich ivory carvings and lost-wax castings in bronze and brass (Martin & O'Meara, 1995). Dahomey became heavily involved in the European slave trade with the arrival of the Dutch (Antrim, 2002). The end of the slave trade in the mid-19th century AD greatly affected the economic fortunes of Dahomey, forcing it to provide primary products for newly important colonial markets. Palm oil, its main export, never generated the same revenues as had the slave trade. After the French gained control of Porto-Novo, commerce declined. In 1892 AD, the French launched a full-scale offensive against Dahomey; its leaders surrendering in 1894 AD, with the kingdom becoming a French colony (Antrim, 2002).

1.5 HORN OF AFRICA - ANCIENT ABYSSINIA (MODERN ETHIOPIA)

1.5.1 Sabaean

At least by 1,000 BC at the latest, Ethiopia, Eritrea and what is now southern Yemen were part of a large empire known as the Sabaean Kingdoms. The earliest known Arabian temple was at Marib (in southern Yemen), capital of Saba (Sheba), and was called Mahram Bilqus, *precincts of the Queen of Saba* or *Makedda* (greatness). Saba had a very matrifocal society with a host of female deities. According to the *Kebra Negast*, a holy book of Ethiopia, it is said that “*Makedda*” (Greatness) herself created a dictate stating, *only a woman can rule*. Polyandry, the practice of taking more than one husband by a woman, and tracing one's kinship based on matrilineal descent was common. Years later, the Jewish historian Josephus, referred to her as *Nikaulis*, *Queen of Ethiopia*. She is the celebrated Queen of Sheba of the Bible who is described as *black and comely* (The Sankofa Project, 1999). Likewise, Diop (1974) considered the Sabaean Kingdom to be dominated by a black culture. According to Diop (1974), at the time, what is modern-day Yemen was a Negro Ethiopian colony, remaining so until the birth of Mohammed in 570 AD, when the black and white races mixed to form Semites that today constitute both Arabs and Jews.

Saba flourished as a trading community in goods from Asia as well as Africa. Even coffee drinkers trace the original cup to Ethiopia's Kefa region. Saba was a center of astronomical wisdom. In Saba the Queen or King was chief astronomer and astrologer. Spiritual religious life involved reverence of celestial bodies such as the sun and moon (The Sankofa Project, 1999).

1.5.2 Aksum

The eastern horn of Africa had been well known during dynastic Egypt as the land of Punt. Roman and Greek sources indicate that an Aksumite (Axumite) kingdom (Figure 1.1) was thriving by the first century AD, the city of Adulis being an important port city. Ethiopian history, however, places Aksum as an ancient city, and the home of the Queen of Sheba at around the first century AD. In the second century AD, Aksum acquired tribute states on the Arabian Peninsula across the Red Sea, conquered northern Ethiopia, and then finally conquered Meroitic Kush (Figure 1.1). The downfall of the Nubian powers led to the swift rise of Aksumite imperial power. The Aksumites controlled one of the most important trade routes and occupied one of the most fertile regions in the world (see Chapter 2, Section 2.3.4.1, Aksum of Ethiopia). Aksum lay directly in the path of the growing commercial trade routes between Africa, Arabia, and India and became fabulously wealthy. Its major cities, Adulis, Aksum, and Matara, were among the most important cosmopolitan centers in the ancient world. An indication of this cosmopolitan character can be found in the fact that the major Aksumite cities had Jewish, Nubian, Christian, and even Buddhist minorities (The Sankofa Project, 1999).

1.5.3 Christian Ethiopia

By the fourth century AD, the religious system of Christian Rome had conquered Egypt and Syria. During the reign of King Ella Amida, he converted to Christianity, which became Ethiopia's state religion. Coptic Christianity flourished in the Nubian kingdoms mostly among the royalty and the monks (The Sankofa Project, 1999).

Muslim conquests in the mid-seventh century AD of Egypt and North Africa left Aksum cutoff from former trade routes. Although Ethiopian tradition indicates that the kings of Ethiopia are of Judaic stock directly descended from Solomon and the Queen of Sheba, Christianity was introduced through mercantile relations. However, with the Muslim takeover of the Red Sea ports and northern Africa, the Christian faith was gradually naturalized and adapted to local conditions. Greek was no longer spoken, minted currency became rare, church construction ceased and pagan worship was revived. Although the strength of Aksum declined, its culture survived to form part of the Ethiopian civilization. The Ethiopian people were born of a fusion of semitized Aksumites and Cushitic¹⁰ highland peasant farmers (July, 1970).

During the ninth century AD, ancient Ethiopia managed to regain control of its Red Sea outlets, maintaining a prevailing southern orientation (July, 1970). As elsewhere, it was surrounded by Muslims. The Aksumites gradually migrated to the mountain districts of Amhara, Gojjam and Shoa, establishing kingdoms in the face of hostile pagans, which resulted in a late tenth century AD revolt of the Agau people who slaughtered the clergy. The Christian monarchy prevailed and thus a nation emerged based on a fusion as opposed to a conquest, with the Christian Aksumites forming the Abyssinian aristocracy, while Ge'ez and Amharic dominated the national languages. The Agau yielded to Christianity by having their religious practices (a combination of Judaism and paganism) integrated into church ritual. At the same time, the Agau emerged as the major ethnic element of the Abyssinian population and eventually gained control of the monarchy in the form of the Christianized Zagwe dynasty that ruled Ethiopia for 150 years from the middle of the 12th century AD. Eleven major churches were built, which represented the emergence of a unique Christianity of Ethiopia following Coptic linkages to the patriarch of Alexandria, Egypt, and close ties

¹⁰ Diop (1974) considered the Kushites (Cushites) to be black.

between the church and the state. Ethnically, the Agau were Semites from Arabia. By 1270 AD, the Solomonid (King of Solomon) line was restored to power and ruled Ethiopia until recent times. In the mid-1400s AD, this dynasty began establishing relationships with Rome as a means of holding back the external influences of Islam. In 1494 AD, Portugal made its first contact with Ethiopia and sent a diplomatic mission 25 years later (July, 1970).

Under pressure from their northern Muslim neighbors, the tributary states (e.g. Ifat, Fatajar, Doaro, Bali and Adal) fell one by one to Islam (July, 1970). This is significant as for centuries to come the greatest threat to Ethiopia would be their Muslim neighbors to the north (The Sankofa Project, 1999). In 1529 AD a powerful army from the Muslim state of Adal under Ahmad ibn Ghazi fought a *jihad* against the infidel Ethiopian emperor Lebna Dengel and defeated him, thereby bringing most of Ethiopia under Muslim rule, laying waste to large areas, destroying much of the artistic and intellectual heritage, converting many people to Islam and forcing the emperor into exile. With the help of 400 Portuguese musketeers, the emperor's successor, his son Galawdewos (1540-1599 AD) defeated the Muslims and killed Ahmad in 1541 AD. This was immediately followed by the invasion of pastoral Cushitic speaking Galla in the mid 1500s AD, forcing the Ethiopians to share their country with these invaders, living side by side for centuries, as strangers and potential enemies. Turks then invaded coastal areas, which the Ethiopians were able to neutralize but not eliminate in 1589 AD. In the early 1600s AD, Portuguese priests came to convert Ethiopians to Roman Catholicism, which resulted in bloody rebellion. The Ethiopian Church was restored in 1632 AD. All of these incursions resulted in Ethiopia withdrawing into xenophobia, while unrelenting pressure from the Galla led to internal decay, fragmentation and collapse of central authority.

The emperor Fasiladas (1632-1667 AD) established a capital at Gondar, an inaccessible retreat in the Amhara Mountains divorcing emperors from their people, while using Galla mercenaries to prop them up. This alienated the emperor from local princes (*ras*). In 1755 AD, a half-Galla king took the throne, which consequently lost all authority. In 1840 AD, civil war resulted in four independent provinces, Shoa, Gojjam, Amhara and Tigre. The isolation of the monarchy had allowed each provincial *ras* to establish his own local state protected by mountainous inaccessibility. This was followed by a period of anarchy and then forceful consolidation by the first of the reformer kings, Kassa. He was eventually crowned king of kings Theodore, *negusa nagast*, in 1855 AD. He attempted to create a unified modern state through administrative reform and a powerful army with modern arms capable of standing up to European hegemony. After defeating both the Italians and then the Mahdist army of the Khalifa of Muslim Sudan, Theodore was mortally wounded and replaced by the Shoan king Menelik II as king of kings or Emperor of Ethiopia in 1889 AD. Emperor Menelik solicited European assistance in modernizing Ethiopia, but also recognized Europe, especially the Italians, French in Djibouti and the British as a threat to his empire's sovereignty. He founded Ethiopia's capital of Addis Ababa in 1886 AD, building roads and bridges, a postal service and telegraph/telephone services by the beginning of the 20th century. At his death in 1913 AD, Ethiopia went through a brief period of uncertainty under the reign of the apostate of Islam, Empress Lij Yasu (Jasu) from 1913-1916, followed by Menelik's daughter, Zauditu as Empress. Upon her death in 1930, the *Ras* Tafari was crowned Emperor Haile Selassie and would lead Ethiopia into the colonial era after being subjugated by the Italians in 1936 using methods counter to the League of Nations and then by the British during the early years of WWII in 1941 AD (July, 1970).

1.6 EASTERN SUDAN (MODERN-DAY SUDAN)

The 20th and 21st century AD conflicts of modern Sudan, with its capital in Khartoum, can be traced back to the 14th century AD.

When the Aksumite armies sacked Meroe, the capital of the Kingdom of Kush (Figure 1.1) in the middle of the fourth century AD, a Negroid group remained in the Nile Valley. These were the Nuba, whose language and culture came to dominate the Nile Valley south of Egypt. Martin and O'Meara (1995) believe that Kush may have been vulnerable to invasion due to environmental degradation from over-grazing and deforestation. By the sixth century AD, the Sudanese kingdoms of Nubia, Maqurra and Alwa had been converted to Christianity through the Empress Theodora of Byzantium. In 652 AD, Nubian archers stood off an attack by a Muslim army from Egypt, which resulted in a treaty between Muslim Egypt and Christian Sudan that lasted for 600 years. These Sudanese kingdoms traded slaves to the north. Christian Nubian civilization prospered along the Nile River with attractive churches, monasteries, gardens, vineyards and rich pasture. The Kingdom of Maqurra spread Christianity as far as Darfur of modern western Sudan. Alwa bred fine horses, camels and cattle. There were 400 churches by the 13th century AD. The arrival of Mamluk rulers (a caste of Turkish and other Asian slaves who seized power in the mid-13th century AD) in Egypt led to large-scale Arab immigration from that country, which resulted in the political collapse of Maqurra in the early 14th century AD. The Alwa were overrun by pastoral Egyptian Arabs by the 15th century AD. Civil war resulted until calm brought about by the Funj sultanate early in the 16th century AD. This opened the way for the spread of Islamic religion and civilization throughout eastern Sudan. Eventually, the Arab and local populations became one, while indigenous organizations gave way to Arab political organization, and Christianity and paganism were replaced by Islamic culture and religion. The

Funj sultanate founded its capital at Sennar on the Blue Nile about 300 km upstream from modern-day Khartoum. It remained in power for 300 years (early 1800s AD) until the invasion and conquest by Muhammad Ali, who originally arrived in Egypt with a troop of Albanian cavalry in support of resistance by the Ottomans (Turks) against the Napoleonic invasion of Egypt. He eventually founded a dynasty of foreign princes (July, 1990). Thus, the northern half of Sudan tended to be Arab and Muslim, while the southern tended to be animist and eventually Christian. Interventions by the British created a Christian stronghold/buffer zone against further advancement of Islam to the south. This will be discussed in more detail in Chapter 13, Section 13.10.1.6, Oil-scorched earth Sudan.

Nilotic pastoralists in the south had little structured government. Neither the Nuer nor Dinka had/have headmen. Among the Dinka, hereditary ritual specialists called “masters of the fishing spear” acted as mediators and used their powers to assure the success of armies made up of lineages called “people of the spear”. A professional mediator among the Nuer, the “leopard-skin chief”, was/is called in when there are disputes. Among the Nuer, if there was an infringement of rights, cattle were taken, or there was individual combat; clubs if within the same village/camps, spears if the dispute is between villages. Only the “leopard-skin chief” could stop warring between villages, namely by hoeing the ground to create a boundary that neither may cross. Feuds could end through the exchange of cattle or through marriage as forms of settlement. Disputes among the Anuak were talked out by headmen or elders with consensus based on a public discussion. If someone killed, the killer left the village until the anger was gone. Only the Shilluk recognized the superiority of an individual, the *Reth*, over the whole of the people, the final authority. The *Reth* was responsible for making sacrifices for rain, victory in war, and performed a rite of reconciliation in the case of blood feuds similar to the “leopard-skin chief”. In most of these pastoral

societies, major wars are/were fought over access to grazing grounds (Mair, 1977).

1.6.1 Southward Expansion of Pastoralism and Livestock into East and Southern Africa

Pastoralists may best be defined as people linked to a system of production who gain their livelihood primarily from the care of large herds by means of transhumance (movements of livestock depending on rainfall and grass/vegetational cover) in semi-arid open country savannas and grasslands where agriculture cannot easily be sustained. They tend to survive by harvesting wild grain, fishing, hunting and even practicing agriculture in good rainfall years (Smith, 1992). In certain cases, pastoralists move into sedentary farming areas during the dry season in a reciprocal relationship, exchanging field stubble as food for livestock in return for manure as a natural fertilizer. In such cases, grains can be obtained through barter.

On the other hand, Agro-pastoralists, while they may see themselves as herdsmen, tend to be more sedentary. However, grains tend to play a large role in their diet and their gardens may be more important to them production wise than their herds, even when animals may be their most valued possessions (Smith, 1992).

The progressive desiccation of the Sahara after about 6,000 years ago (4,000 BC) resulted in water shortages and the southward retreat of the tsetse belt opened up new grasslands to pastoralism in West Africa. Sudan south of the confluence of the Blue Nile and White Nile rivers would also have permitted the exploitation of grasslands of the Upper Nile and East Africa. It is suggested that the influence on Southern Sudan came from the central Sahara and not from Pharaonic Egypt. By 4,000 years ago (2,000 BC), pastoralism was found around Lake Turkana (Smith, 1992). Between 4,000 and 3,000 years ago (2,000 and 1,000 BC), herding

became established in southern Kenya and Tanzania (Martin & O'Meara, 1995). Vande weghe (2004) believes that dense moist forests from the slopes of the Rwenzori Mountains (Albertine rift of present-day western Uganda) to Lake Victoria (eastern boundary of present-day Uganda) prevented pastoralists from the north from penetrating into southern Uganda, Rwanda, Burundi and today's eastern Democratic Republic of Congo until about 3,800 years ago (1,800 BC), but more likely between 2,500 and 2,000 years ago (500 and 0 BC) when drying conditions resulted in fragmentation of this forest.

By the time iron-using Bantu agriculturalists arrived in East Africa around 2,100 years ago (100 BC), Nilotc pastoralists were well established in East Africa (Smith 1992). Nilotc pastoral tribes migrating southward included Karamojong, Tutsi, Hima, Huma and Luo in Uganda, Turkana, Nandi, Kipsigis, Maasai and Luo in Kenya, and Tutsi in Rwanda and Burundi. Government was minimal. Chrétien (2003) and Chua (2003) dispute the origins of Tutsi and Hima as Nilotc (see below), believing them to be Bantu in origin.

The Turkana believed in self-help and did not recognize mediators. Stock was taken by force if one was wronged. When fighting for one's rights, one relied on support from lineage groups and friends whose allegiance was won through gifts of cattle. The oldest men in the community were believed to have ties to the ancestors. The Kipsigis believed in blood feuds and the right to seize cattle (Mair, 1977).

West of Lake Turkana, the majority of the pastoralists are Nilotc. East of Lake Turkana, they are Cushitic-speaking divided into two mutually unintelligible linguistic sub-groups; Oram (spoken by Oromo and Borana) and Somaloid (spoken by Rendille and Somali). The Cushitic-speaking camel herding Rendille and Nilotc-speaking cattle herding Samburu have experienced exchange, co-

operation and intermarriage for a long time. Because camels breed slower than cattle, the Rendille were unable to maintain camel production at the same rate as human production and were forced into Samburu areas to become cattle herders, facilitated by the above relationships. What is unclear is the timing of arrival in East Africa (Kenya) of these Cushitic-speaking pastoralists; some sources see them as a second wave of pastoral immigrant following the arrival of the Nilotics, while others see them as pre-dating the arrival of the Nilotics by 2,500 years (Smith, 1992).

The iron-using Bantu lived and worked in wooded environments unavailable to the pastoralists and in an almost symbiotic relationship created grasslands through fire and bush clearance. In many cases, these cleared areas were gradually taken over by pastoralists. This interface between pastoralists and agriculturalists meant acceptance of economic activities across cultural boundaries. Smith (1992) suggests that the iron using cultures that appeared in the inter-lacustrine area around 2,000 years ago (\approx 0 AD) did not expand into the Kenya Highlands (e.g., Kikuyu farmers) until much later, probably due to the size of the pastoral populations that prevented invasions of their territory. July (1970) places the arrival of the Bantu into East Africa as around the first or second century AD. The Bantu, who had food storing capabilities moved into Tanzania, Malawi and Zambia around 1,800 years ago (\approx 200 AD) and the Highveld of South Africa around 1,600 BP (\approx 400 AD) (Smith, 1992). Livestock followed at a similar pace. It is hypothesized that as Bantu farmers cleared the bush, creating pasture and pushing back the tsetse fly belt, war-like pastoralists may have displaced these agro-pastoralists/agriculturalists, continually pushing these Bantu iron-using people southward (Smith, 1992).

Likewise, Vande weghe (2004) hypothesizes that unlike the western Bantus whose population densities remained low, the eastern Bantus' population, whose

agriculture was based on sorghum, finger millet and bananas, grew rapidly exceeding four persons/km² while advancing on a broad front with abandoned lands being taken over by pastoralists. In the case of Rwanda and Burundi, agriculturalists created high altitude grasslands where they had never existed, namely in cooler uplands (Vande weghe, 2004). These highlands were healthier for livestock and people, free of tsetse fly and mosquito vectors for sleeping sickness and malaria, respectively, allowing the populations of both to grow (Vande weghe, 2004; Diamond, 2005). Of course, this ended any possibility of these lands going back into forests, the situation which persists to the present day and which is continually worsening (see Chapter 5, Section 5.9.4.6, Deforestation in afromontane forests - Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Political Destabilization).

It is believed that the most likely movement of livestock accompanying iron-using agro-pastoralists from East to Southern Africa took place in the inter-lacustrine area of East Africa, downward through the tsetse-free corridors of the Tanzanian Highlands and Malawi to Zimbabwe and the Transvaal of South Africa (Huffman, 1979; Phillipson, 1985 *In:* Smith, 1992). By the end of the first millennium BC, iron using Bantu had displaced hunter-gatherers south of the East African Highland zone in Central Tanzania (Smith, 1992). It is believed that the Bantu agro-pastoralists spread into lands occupied by hunter-gatherers (e.g., San) who were incorporated into agro-pastoral society as low-status members. Flocks of small stock (e.g., sheep) exchanged hands and many former hunters became herders in their own rights (e.g., Khoi of the Western Cape as early as 1,960 +/- 95 years ago (\approx first Century AD). From skeletal remains of Khoisan-speaking groups¹¹ in Zambia, and Malawi as late as the third century AD, it is suggested that southern Zambia and Malawi could have been part of a geographical area of conflict between Bantu and Khoisan peoples during this expansive period of food-

¹¹ Khoisan is a term used by linguists for groups speaking a click language

producing societies; however this possibility needs further research (Smith, 1992). Martin and O'Meara (1995) argue that the spread of herding and agriculture south of Tanzania was blocked for about 2,000 years, arguably due to the extremely successful hunter-gatherer adaptation of the Khoisan-speaking people of southern Africa. Although the Hadza and Sandawe hunter-gatherers of East Africa spoke a click language, neither can be shown to be related to each other nor to the Bushmen/Khoi languages of Southern Africa. Some sources even question how closely the Khoi/Khoikhoi/Hotentot and Bushmen languages are related (Smith, 1992) [see Section 1.7.3.1, Khoisan-speaking groups (click language)].

In the second half of the 19th century AD, the Maa-speaking people's (Maasai) southward movement along the Rift Valley was blocked by more powerful neighbors, turning them back and resulting in internecine conflicts called the Maasai Civil Wars. At the same time, the Turkana moved into their current region in northwestern Kenya. When the Europeans entered East Africa, these movements were still taking place (Martin & O'Meara, 1995).

1.7 BANTU AFRICA

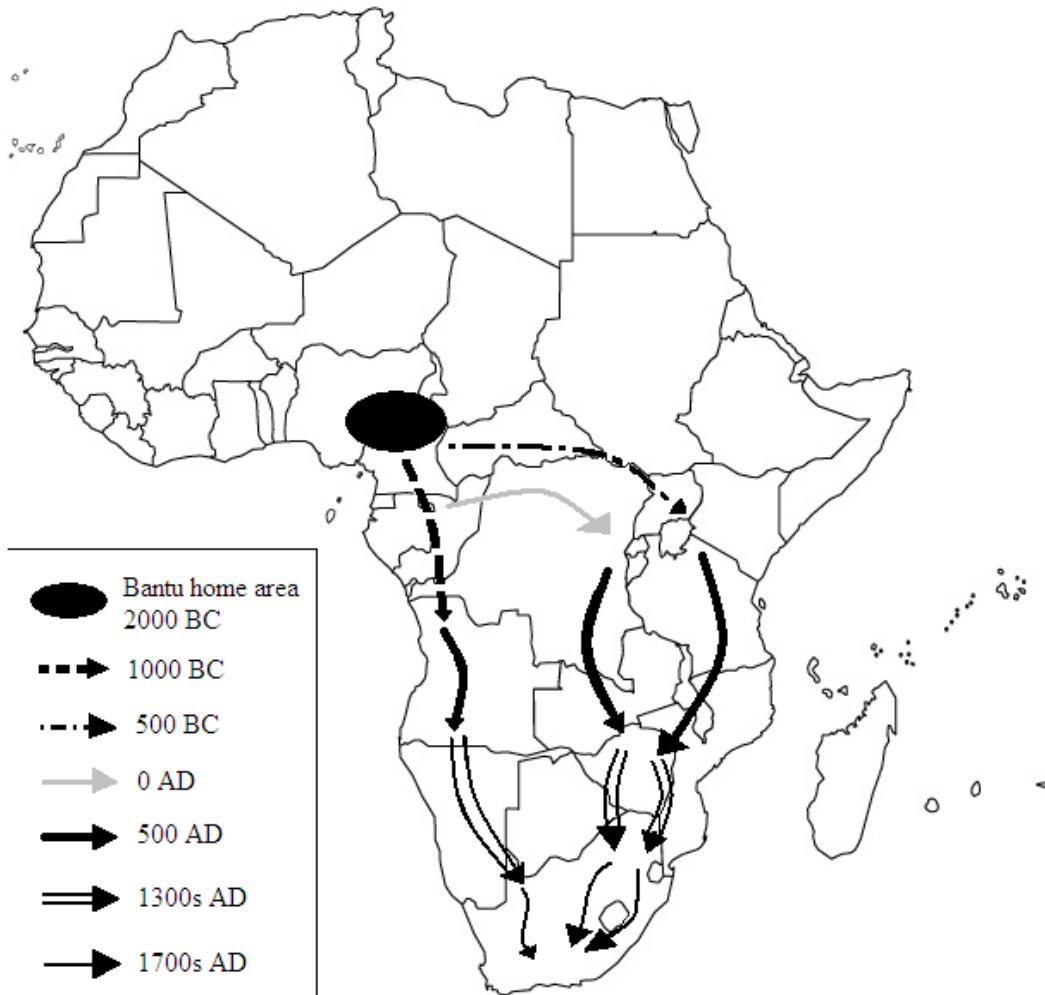

From 10,000 years ago (8,000 BC) to about, 6,000 years ago (4,000 BC) (Martin & O'Meara, 1995)/5,000 years ago (3,000 BC) (Chrétien, 2003) Africa experienced a long humid phase, significant for development in the Sahara. From about 4,000 to 3,000 years ago (second and first millennia BC) the continent began drying out from a combination of decreased rainfall and human land clearing/deforestation. By about 1,000 AD, this began forcing people to move in search of a more amicable climate, resulting in a southward agricultural movement (Chrétien, 2003). July (1970) places the beginning of the Bantu migration at about the time of Christ. Vande weghe (2004) places the migration

beginning about 5,000 years ago (3,000 BC) as the result of a drought that peaked somewhere between 2,000 to 3,000 years ago (1,000 BC to 0 AD).

- Bantu does not refer to one language but to a conglomeration of more than 450 (Kongo-Niger language group), whose origins can be traced to the cradle land where between the second and fourth centuries AD, Bantu speakers from western Cameroon (Adamoua Plateau of Cameroon) and eastern Nigeria spread southward (Martin & O'Meara, 1995; Vande weghe, 2004). July (1970) and Kake (1983) place the focal point of this migration at the central Bénoué River Valley coming off the Adamoua Plateau. The Bantu first spread through the forests and gradually into the savannas (Figure 1.4). They cultivated root crops, fished, hunted and kept goats. Their expansion was not militaristic, but a slow integration and absorption of other cultures (July, 1970; Martin & O'Meara, 1995). In less than 4,000 years they would colonize all of Central Africa and most of East and Southern Africa (Vande weghe, 2004), terminating their southerly movement at the Fish River of South Africa.

Vande weghe (2004) explains that this movement was split between the eastern and western Bantus. The western Bantus heading southward arrived along the coasts, watercourses and grasslands (Vande weghe, 2004):

- They arrived at the Sanaga River in present-day Cameroon about 4,000 years ago (BP) (2,000 BC).
- About 3,000 years ago (1,000 BC) they occupied most of the forests lying between the Atlantic Ocean and the great swamps of the central Congo Basin bordered by the Sangha River, Ubangi River and Congo River.
- By 2,000 years (0 AD) ago, they had gone around these swamps and reached the northeast part of the forest massif.

Source: Principal authors

Figure 1.4: Bantu migrations through Sub-Saharan Africa

By 1,500 years ago (500 AD) they had conquered all the Congo Basin and continued south to the Cunene River on the Angola/Namibian border, the middle Zambezi and the present Malawi/Zambia border.

The eastern Bantu migrated north of the great forests following a savanna route, reaching the Great Lakes region about 2,500 years ago (500 BC). From there some colonized the eastern part of the Congo Basin and the savannas just south of the forest massif, in East and Southern Africa. Ubangian and central Sudanian

peoples joined and were absorbed by the Bantus around the forest massif. South of the forest massif, western and eastern Bantus mingled (Vande weghe, 2004).

The history of the Bantu take over of East, Central and Southern Africa begins around the first or second century AD, the Bantu crossing the Limpopo River into what is now South Africa at between the 4th (July 1970)/5th (Smith, 1992) centuries AD and the 14th century AD (July, 1970), and ends with the most southern migration around the 18th century AD, somewhere between 1702 (Diamond, 1997) and the mid-1700s AD (Martin & O'Meara, 1995). The Xhosa clashed with the northern moving Afrikaner Boers and it took nine wars and 175 years for Boer armies advancing at a rate of less than 1.6 km (1 mile)/year to subdue the Xhosa (Diamond, 1997)¹². The southerly movement of the Bantu (Xhosa) was stopped at the Fish River by a lack of winter rainfall crops, which, however the Afrikaners brought in, thereby allowing them to settle in this temperate climate zone (see Section 1.1.5, Development of Modern Societies with an Agricultural Base).

July (1970) points to periodic explosive militaristic conquests, most likely due to land hunger, such as the sudden movement of Jaga into the Kongo and Angola in the late 16th century AD (late 1500s AD) from the African interior, the attacks by the Zimba from Malawi who devastated the East African coast and the early 19th century AD (early 1800s AD) population explosions in Southern Africa, which spurned the military conquests of Shaka Zulu.

According to Kake (1983), the Jaga and Zimba were basically the same group of people, whose origins can be linked to the Maasai or close relatives from the Great Lakes region. Similar to the Zulus, they were nomads made up of military companies instead of villages. The Jaga and Zimba used surprise attacks, killing

¹² Encyclopedia Britannica (2004) calls these the Cape Frontier Wars or Kaffir Wars lasting 100 years from 1779-1879

most of their victims except the women and young men, the latter being recruited for the military. In addition, they practiced cannibalism and infanticide. As the Jaga and Zimba moved through the Congo, they were absorbed into the Bantu culture, which they conquered and into which they married, thereby becoming *bantouisés*. Kake (1983) goes on to say that they helped the people they conquered, for example the Ba-Lunda, Ba-Bemba, Ba-Bisa, Ba-Yaka, Ba-Nano Ba-Songo and Ba-Rotse, with the formation of states. From the 16th–17th century AD, the Jaga and Zimba left behind a trail of fire and blood from Sierra Leone to the Zambezi and from Ethiopia to the Kalahari, but at the same time are considered the ancestors of the Ba-Yaka of the Congo, the Jinga of Angola, the Azimba of the Zambezi, the Vazimba of Madagascar, the Galla of Abyssinia, the Fundi of Sennar, the Timene of Sierra Leone, the Makalaka of Zimbabwe, the Pahouins and the Zulus.

Initially, the less agriculturally productive savanna areas were left vacant by the Bantu, while Nilotic-speaking (modern-day Sudan) and Cushitic-speaking (southern Ethiopia) people moved into these areas (see Section 1.6.1, Southward Expansion of Pastoralism and Livestock into East and Southern Africa). It is believed that the Cushitic and central Sudan-speaking people may have introduced the Bantu to dry cereal grains (although the Bantu would have brought certain varieties of sorghum and millet from the Sahel and yams from the Sudano regions), as well as irrigation and livestock (Martin & O'Meara, 1995). The Bantu did not move across East and Southern Africa in large numbers, but instead in small lineage groups. Their economy was based on “shifting cultivation” also called “slash and burn”, itinerant agriculture and *jachère* (see Chapter 2, Section 2.3.3, Fallow Agriculture in Low Productive Areas). As population pressures built up and nutrients were leached out of the soils, they were forced to move in search of new land (July, 1970; Martin & O'Meara, 1995). Bantu cultivation made possible a steadily growing population, which in turn acted as a propellant

for migration in response to issues related to marriage, inheritance, lineage and dissatisfaction with political or economic rights (July, 1970). While Martin and O'Meara (1995) call this a slow and gradual, not rapid process, July (1970) believes that a combination of soil exhaustion and population increases produced a rapid and dynamic migration. Likewise as noted in Section 1.6.1, Southward Expansion of Pastoralism and Livestock into East and Southern Africa, Smith (1992) suggests that as agriculturists cleared the bush, thereby pushing back the tsetse fly and its habitat, war-like pastoralists may have displaced these agro-pastoralists/agriculturalists, continually pushing the iron-using Bantu people southward (Smith, 1992).

Gradually the Bantu language dominated East and Southern Africa. It is believed this is because the Bantu were technologically superior compared to the pastoralists and the Khoisan hunter and gatherer. "Bantuization equaled urbanization" where the Bantu lived in compact settlements which other groups visited for trading purposes, and into which many of them were absorbed through marriage. As a result, many of these groups began speaking the Bantu languages (Martin & O'Meara, 1995).

Land hunger and habitat degradation has been and will continue to be a growing issue in the 21st century AD unless Sub-Saharan Africa and the global community address subsistence agriculture and transhumance. As described in this chapter and Chapter 2, these lifestyles can no longer sustain the majority of Africa's population. It will be necessary to train farmers to link traditional management systems to new technologies, while finding alternative livelihoods for the majority of the youth growing up in 21st century AD rural Africa. The reasons for the inability of the land to support 20th/21st century AD rural populations in Sub-Saharan Africa, as well as possible solutions to this problem are discussed thoroughly in Chapters 5 through 13.

1.7.1 Central Africa

1.7.1.1 Congo kingdoms

The people living in the Congo Forest did not have a highly centralized state like Great Zimbabwe to the south, being organized in small states or no states at all. Historians have suggested that organization consisted of small clearly defined geographical areas headed by a chief and a council of elders who led a number of villages, likely linked through kinship. The land was sparsely inhabited because of the density of the tropical rainforest. People were involved in both agricultural and hunting/gathering activities (ANON, 2002a).

By around 1400 AD, pastoralists had entered the savanna regions to the east and southeast of the forest. Some historians have speculated that through interaction between pastoralists and agriculturalists, institutionalized states were formed (ANON, 2002a), including the (Hempstone, 1962; Young, 2000):

- **Bakongo Kingdom.** In the mid-13th or 14th century AD, Kongo kings organized mostly matrilineal agricultural settlements, surrounding the mouth of the Congo River, into provinces, collected taxes, and established an official currency of shells.
- **Ndongo Kingdom.** South of the Bakongo people, in the early 16th century AD, the centralized Ndongo controlled the trade in salt and iron.
- **Baluba Kingdom.** The first great Bantu Kingdom, the Baluba Empire was founded in the 15th century AD by Kongolo Mukulu. At its apogee this empire, which lasted 200 years, was larger than Belgium, Holland and Luxembourg combined.
- **Lunda Kingdom.** Later in the 16th century AD, the Lunda formed a kingdom in the grasslands of the upper Kasai River (consisting of a

territory extending from modern-day Angola, Kasai province of the DRC south through present-day Katanga into northern Zambia), which began to eclipse the Baluba. The chief Mwata Yamo's kingdom was larger than the Baluba and at its peak was larger than Portugal. It became an arch enemy of the Baluba Kingdom.

The Bakongo Kingdom was once one of Africa's greatest empires, establishing diplomatic relations on a basis of equality with several European states. Its kings and courts were Christian and literate in Portuguese. It was one of the few African states to play a part in world history from medieval times almost until the present. The Bakongo lived on both sides of the Congo River. Their territory extended far into modern-day Angola to its eastern boundary with present-day DRC, the Kwango River. The center of the kingdom was the south bank of the Congo River (Figure 1.1). The political structure was similar to Europe in the Middle Ages with the country divided into districts run by vassal princes. They caste iron and copper, made bark cloth which the Portuguese traders used as sails, produced pottery and farmed with millet, bananas, peas, squash and yams. In 1484 AD, the Bakongo monarch, Nzinga Ntinu, sent ambassadors to Lisbon to request technical assistance in masonry, carpentry and religion. The king converted to Catholicism in 1484 AD and his son and successor Don Alfonso and eventually the king's grandson son Don Alvaro were made bishops. Ambassadors were sent to both Spain and the Vatican, and a Papal Nuncio was sent to reside in Mbanza. The Portuguese introduced the slave trade to supply Sao Tomé, Brazil and other New World communities, Don Alfonso being a principal supplier. The kingdom began to decline after being attacked by the Jaga tribe, the Portuguese coming to their defense in 1580 AD. However, in 1590 AD, the Bakongo declared war against the Portuguese under Don Alvaro II, while trying to have their kingdom placed under a Papal trusteeship for protection. This was followed by a short-lived takeover of Luanda by the Dutch in 1641 AD and a crushing

defeat by the Portuguese in 1665 AD at the battle of Mpika. Weakened by war and the slave trade, the Bakongo Kingdom saw a rapid decline, which by 1885 AD resulted in it being divided by the French, Belgians and Portuguese (Hempstone, 1962).

Both the Baluba and Lunda Kingdoms (Figure 1.1) depended upon military skill and political organization for their success (Hempstone, 1962). The Luba and Lunda Empires are believed to have had their center of development emanating from Lake Kisale (July, 1970) west of Mitwaba and on the northern border of the modern day *Parc National de l'Upemba* in what is now southeastern DRC.

The political unification of the Luba Empire was maintained by a hierarchy of chiefdoms, which served as an intermediary between the king and the village. Several villages formed a territorial chiefdom gathered into provinces combined to form a central state. With the exception of village headmen, all chiefs derived their power from the *balopwe*, members of the ruling lineage of Kongolo and his son Kalala Ilunga. Close relatives of the king held major titles in central government, including head of the army and police force. Expansion to the east and south brought on tributary states rather than provinces; conquering Lunda to the west in 1600 AD and consummated by the son of Kalala, Cibinda Ilunga marrying the Lunda queen to become king. He immediately divorced himself from the Luba Empire, creating his own independent state (July, 1970).

The Lunda Kingdom's (Figure 1.1) cohesiveness depended on the institution of perpetual kinship, which linked all village headmen to each other and to the king, with a new headman inheriting all his predecessor's kinship relations and his name. This resulted in local self-governance, the royal power refraining from interference in provincial affairs as long as taxes were paid. The king or *Mwata Ymvo* (Lord of the Viper) was represented by a district political officer, *cilool*,

nominated by local headsmen and acting as the tax collector. As with the Luba, the system of indirect rule in the provinces greatly diminished the authority of the Lunda king. The Lunda culture spread south and west into modern-day Zambia and Angola, as a result of breakaway groups deciding to form their own kingdoms, such as the Bisa and Bembe in Zambia and the Chokwe in southeastern DRC/Angola. The spread of this culture greatly influenced civilization in the Congo/Zambezi Basins until the 19th century AD (July, 1970).

The decline of the Lunda Empire at the end of the 17th century AD was brought about by two factors, the slave trade or export of “black ivory” by *pombieros* (half-caste Portuguese traders) from Angola taking slaves to the New World, and the supply of women to harems in Muscat and Oman by Arabs from the east. Both groups had firearms, at the time unavailable to these Bantu kingdoms. The 1885 AD revolt by the Chokwe tribe of hunters and warriors, formerly allied to the Lunda, resulted in the eclipse of the Lundas for 75 years (Hempstone, 1962).

Congo, Europe, Arabs, the Slave Trade and Devastation of Societies

Long before the conquest of the vast Congo hinterland, the coastal communities had had centuries of contact with Europeans. The area of the Congo was one of the principal sources of slaves to markets in Arabia, the Middle East and the New World. The slave trade had devastating effects on both Kongo and non-Kongo communities for almost 400 years. By the late 17th century AD, up to 15,000 slaves a year were sent out of the lower Congo River area (ANON, 1993). In the first half of the 19th century AD an estimated 7.5 million Congolese slaves, 150,000/year were shipped to the New World from West African ports (Hempstone, 1962).

The European slave traders were usually the final link in a chain of African and Arab merchants who brought slaves down to coastal trading posts. The slave trade in the eastern part of present-day DRC/Zaire was dominated by Arabs and continued until the late 19th century. All European nations had abolished the trade by the mid-19th century AD, and the end of the American Civil War in 1865 AD extinguished another main market. Besides obviously causing substantial depopulation, the slave trade in the Congo area also led to many local rebellions and increased ethnic warfare (ANON, 1993).

On the eve of the Belgian conquest in the late 19th century AD, Congolese societies had reached a degree of internal dislocation that greatly lessened their capacity to resist a full-scale invasion. The dynamics of internal fragmentation were directly linked to commercial activities. As the ownership of slaves became a major source of wealth and prestige, this in turn made it possible for the slave owners to challenge the authority of the king. Here, as elsewhere in the savanna, the competition for slaves introduced a major source of instability brought about by the divisions between “collaborators” and “resisters” and between the allies of the Arabs and the allies of the Europeans. This created a permanent state of social unrest and civil war and hampered African resistance to outside forces. The situation was exacerbated further by the subsequent improvement in the capacity of Africans to destroy each other through the use of firearms. In addition, a more enduring cleavage had emerged out of the varying exposure of Congolese societies to Western influences and early trade activities. The history of the old Kongo Kingdom encapsulates many of the crises experienced by several other states of the savanna in their efforts to cope with the challenge of the new economic forces (ANON, 1993).

1.7.1.2 Pygmies

Diop (1974) believes that the Pygmies were the first inhabitants of the African interior. Humans have inhabited the Congo Basin for at least 70,000 years. About 20,000 to 25,000 years ago, the first groups of humans began invading the forests; the offspring were the Pygmies. During this period, the Pygmies and tall blacks (Bantu, Ubangi and central Sudanic speaking peoples) diverged. Ranging from western Cameroon east to Uganda, Rwanda and Burundi, and showing some rare genes in common, the eastern and western Pygmies became separated from each other about 15,000 years ago. Their separation took place isolated during forest fragmentation of the last glaciation, and they never regained contact when the forests recovered. Three main ethnic groups developed among the Pygmies (Vande weghe, 2004):

- The Kola and Bongo in Cameroon and Gabon;
- The Aka, Baka (also in Cameroon), Asua, Mbuti and Efe north of the Congo River; and
- The Cwa south of the Congo River and Twa east in Kivu (DRC), Rwanda and Burundi

The fragmented distribution of an estimated 200,000 Pygmies scattered among 120 million blacks suggests that the Pygmy hunters were formerly widespread throughout the equatorial forests until displaced and isolated by arriving black farmers and compressed into the forests (Diamond, 1997). These refuges must have increased their isolation and accentuated their specialization (Vande weghe, 2004). The Pygmies did not have a distinct language, adopting that of the Bantus living in their vicinity (Diamond, 1997). This resulted in the formation of a master servant relationship between these two groups. Vande wege (2004) argues that the introduction of exotic crops such as banana, stimulated the growth of

farming populations and contributed to the Pygmies' dependence and eventual marginalization. In some areas, researchers have demonstrated that Pygmies are so dependent on starches provided by "black" farmers that they could never have survived on forest resources alone (Vande weghe, 2004), especially as their relatively small populations increased in relation to forest resources. Given the expulsion of Pygmies from their forests and the latter's decline as a result of logging and Western conservation movements at the beginning of the 21st century, the future of the Pygmy as a distinct culture is put into question [See Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the "*Dobi Dobi*", More Parks and Protected Areas and Section 11.11.7, Case Study Bongo in the Congo (Brazzaville)].

1.7.2 East Africa

1.7.2.1 Great Lakes

The Great Lakes of Africa include Lake Victoria, Lake Albert, Lake Tanganyika, and Lake Nyasa (Malawi), which are all located in East Africa. The *Chewzi* stories are oral histories that have helped piece together the background of this region. Historians tie the concerns in the *Chewzi* stories to the time when pastoralists and agriculturalists were living side by side. Evidence shows that salt and iron trades existed during this period. Most historians believe that this region, like the Congo Forest, was ruled at a local level until around the 15th century AD when large states began to form. This was also the time when coexistence between pastoralists and agriculturalists started to become less peaceful and social classes or castes began to form among them (ANON, 2002a).

The introduction of Southeast Asian food crops, especially bananas, is believed to have allowed the movement from decentralized egalitarian communities that had

developed throughout East Africa to Bantu-speaking centralized states in the inter-lacustrine (between lakes) area. The largest of these states was Kitara, located in what is now southern Uganda and made up of Bantu-speakers known as “god-kings” called *Abatembuzi*. In the 14th century AD, this dynasty was supplanted by the *Abachwezi* dynasty, pastoralists from the north known today as the Tutsi of Rwanda and Burundi (Figure 1.1) (Martin & O’Meara, 1995; Madsen, 1999). Finally, around 1450 AD, the last group to move into the area were the Lwoo who supplanted the Abachwezi, causing the disintegration of the Kitara state into a number of smaller yet still highly centralized kingdoms such as the Bunyoro and Buganda (of modern-day Kampala), the Acholi Kingdom to the north and the Ja-Luo Kingdom, a tribe still found around Lake Victoria (Martin & O’Meara, 1995). Eventually six major kingdoms arose: 1) Buganda based mainly on banana growing in sub-montane forests along Lake Victoria, and in higher altitudes along the Albertine Rift, 2) Bunyoro, 3) Toro, 4) Ankole, 5) Rwanda and 6) Burundi (Vande weghe, 2004).

Both July (1970) and Madsen (1999) support the idea that Nilotic pastoralists moved into Uganda, Rwanda and Burundi. Mair (1977) provides an intermediate position, supporting the idea based upon language, that the Tutsi/Hima/Huma/Luo were Nilotic pastoralists, with Hutu and Iru being Bantu cultivators. The relationship between the two groups was more about divisions of labor than castes, with the caveat that the Hutu and Iru tended herds for the Tutsi/Hima. In some places in Uganda (Buha), the Tutsi cultivated and maintained cattle. Some intermarriage took place, basing one’s position in society on lineage and not physical appearance. A patron-client relationship appeared to exist between the Hutu and Tutsi of Rwanda, though this was voluntary. As a client, one could change patrons or have more than one and in fact even be given cattle, blurring the line of division between pastoralist and cultivator. In Uganda, the Iru could only own barren cattle. Mair (1977) speaks of a few instances where there were

Hutu chiefs, but claims this was rare. She also believes that while the Hutu followed armies into war, they did not fight and could not share in the booty.

Chrétien (2003) takes a more extreme view throwing into question much of the history about the Bantu migrations and the development of the Great Lakes region. There appears to be differing opinions as to the origins of the Bantu: Cameroon/Central Africa versus Katanga/Zambia, and as to whether they already had iron-making capabilities. The oral history of the Mbukushu of the Okavango Delta, Botswana states that their ancestors came from the area of Cameroon (Mangurunga, *pers. comm.*). Chrétien (2003) and Chua (2003) contend that Eurocentric beliefs of the existence of an inferior black Bantu race (e.g., the Hutu of Rwanda and Burundi, the Iru of Ankole, Uganda) dominated by superior white-in-origin (e.g., Nilo-Hamitic pastoralists such as the Tutsi of Rwanda and Burundi, and Hima of Ankole, Uganda) ethnic groups were racially based.

Chrétien's (2003) analysis of both Francophone and Anglophone archives leads him to conclude the following. The Hutu/Tutsi and Ira/Hima divisions were as much economic divisions of labor (e.g., farming for Hutu versus pastoralism for Tutsi) which impacted on diet, lifestyle and eventually also on physical characteristics. The idea of a Nilot or Hamitic invasion is questioned along with support for the concept of Bantu pastoralism in the Great Lakes region, similar to that in Bantu-speaking populations of Southern Africa, before 1000 AD. There was a collaborative relationship between pastoralist and farmer, one of providing manure to fertilize the fields and food in return. Similar divisions of labor are seen elsewhere in Africa such as among the Pokot of Kenya, a Nilot-Hamitic culture, where there are *pi pa tix* or cattle people and *pi pa pax* or corn people (Consolata Fathers, 1990). Diamond (2005) likewise raises the question as to whether the Hutu and Tutsi had different origins or whether they were different socio-economic groups within Rwanda and Burundi, a situation that was

exasperated by colonialism. He estimates that 25% of Rwandans have both Hutu and Tutsi grandparents and that both groups speak the same language.

Chrétien (2003) believes that a socio-economic cleavage within the Bantu community developed between largely agricultural groups and pastoral ones, each inhabiting a different ecological niche. This was exacerbated by droughts in the 1620s AD, 1720-1730 AD, 1750-1760 AD and 1780-1790 AD, after which the region was relatively free of ecological catastrophes until the 1890s AD (see Chapter 3, Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya). These droughts and resulting famines saw those with large cattle herds who were resource-mobile seeking out new lands, while the largely resource-immobile agriculturists developed pastoral dependencies as a means of survival, thereby solidifying the evolution of Tutsi and Hima elites in the Great Lakes region. However, the lines between pastoral elites and subservient agriculturists were not that clearly defined. Hutu versus Tutsi might be considered more of a status than ethnicity. Clearly, the notion of “Tutsi” lord and “Hutu” serf was not part of the ancient reality, despite the development of centralized authorities that by the 18th century AD began increasing privileges to Tutsi “pastoralists”. For example, in Burundi both Hutu and Tutsi chiefs were in charge of territories and managed royal land in the center of the country. In Rwanda clan membership prevailed over so-called ethnic membership, with clan lineage being important at a local level, while Hutu subservience to the superior Tutsi was designated at the socio-political level of the kingdom. However, in the 18 century AD Rwandan combined Hutu/Tutsi armies under control of “bow chiefs” became known as “bovine armies” and were allocated prestigious long-horned “Ankole” cattle. This contributed to the “fetishization of cattle” and a growing Hutu-Tutsi socio-political cleavage, which meant a division between groups whose lifestyle was more dominated by agriculture, though they might have some cattle, and those dominated more by livestock, though they might have some fields. Those “Hutu”

agriculturists who were promoted by the kingdom and gained wealth through livestock became “de-Hutuized”.

Colonialism would exacerbate this cleavage based on misunderstood racist interpretations that promoted the theory of a superior white-in-origin pastoral elite from the Horn of Africa destined to rule with European support. The creation of preferential education for a Tutsi minority and their institutionalization into a European-installed bureaucracy formalized and legitimized the unequal relationship between Hutu and Tutsi. This resulted in the creation of a neo-feudal structure, and the “racism” that contributed to the 1994 AD genocide in Rwanda and Burundi resulting in the deaths of over 1 million people, both Tutsi and Hutu, and the anarchy that still permeates from this region (Gourevitch, 1998; Chrétien, 2003) (see Chapter 13, Section 13.8.6, Former Cold War Allies Vying for Power in the Great Lakes Region).

There were two main rural systems in the pre-colonial Great Lakes area: 1) banana gardens and fisheries in the low riparian plateaus along Lake Victoria and the depression of Lake Tanganyika and 2) a mixture of cultivation and cattle herding in the western mountains of Rwanda, Burundi, southwest Uganda and the Kivu plateaus.

The banana tree, South Asian in origin, revolutionized agricultural production and spread into the Great Lakes region of Africa between 3,000 and 2,800 years ago (1,000 and 800 BC) from its entry point along the Zambezi valley and the Horn of Africa. The advantages of the banana tree were 1) simple propagation through cutting, 2) enabling year round farming and providing a year round source of food, 3) yields starting one and a half years after planting 4) flexibility in schedules and spacing of harvests, 5) ease of cooking, 6) use of leaves for roofing and matting, 7) providing green manure humus for gardens, thereby opening up

inter-cropping and 8) freeing up the male population for other pursuits such as hunting and fishing to provide protein (Chrétien, 2003).

A second agricultural revolution began between the 17th and 19th centuries AD with the arrival of New World sweet potato, cassava, maize and beans (e.g., *Phaseolus vulgaris*), groundnuts/peanuts in the dryer areas and tobacco from the Atlantic, supplanting traditional root crops such as *Vigna* legumes (Table 1.1). Maize and beans were already in place when the Europeans arrived in the mid-19th century AD, while cassava spread through colonial rule (Chrétien, 2003). A maize-bean revolution enabled the intensification of agriculture with two harvest seasons. According to Vande weghe (2004), the Zanzibaris-Arabs from Oman, who were heavily involved in the slave and ivory trade out of the Great Lakes region in the 19th century, introduced rice (*Oryza sativa*), mangoes (*Mangifera indica*) and the kapok tree (*Ceiba pentandra*). By 1894, the Zanzibaris-Arabs influence was over, defeated at war by the Belgians.

The success of agriculture accounts for the high human densities present in the Great Lakes region experienced today. It also freed up the male population for other activities such as war, commerce and hunting/fishing, helping the slow evolution from clans to allegiances. This lead from the development of 17th century AD kingships and their territorial expansion to the formation of monarchies in the 18th and 19th centuries AD, such as Rwanda and Burundi that by the late 1800s AD controlled 2 million inhabitants each. Today (2004/5), human populations in the highland areas (e.g., Rwanda and Burundi) have up to 200 people/km², while even a century ago, with a population four to five times smaller, the land was believed to be beyond its carrying capacity. This has resulted in some of the greatest deforestation anywhere in Africa with only a few forested pockets remaining on the highest mountain peaks (e.g., Virungas where some of the last mountain gorillas [*Gorilla gorilla beringei*] are found) (Chrétien,

2003). As is seen in subsequent chapters (see Chapter 5, Section 5.9.4.6, Deforestation in afromontane forests - Rwanda, over-population and land degradation linked to deforestation for agriculture and political destabilization and Chapter 13, Section 13.8.6, Former Cold War Allies Vying for Power in the Great Lakes Region) population pressures and environmental degradation have worsened the Hutu/Tutsi cleavage in the 20th and 21st centuries AD.

1.7.2.2 Kikuyu of the Kenya Highlands

The Kikuyu Bantu culture remained as small village societies regulated by lineage and age groups, with no centralization into states, kingdoms or empires, but was still able to demonstrate strong political and social cohesion. The origins of the Kikuyu agricultural community of the Kenya Highlands appears to be from Shungwaya in southern Somalia. There were no chiefs. Unity was maintained through the family, clan, community and age group. Individual initiative was strongly discouraged in favor of the common good. The head of the family was the father (elder); there was a village and district councils of family heads and from the latter a national council of elders was chosen. In addition, the youth had a council, which also dealt with military affairs. This form of government was egalitarian with decisions based on group discussions. The age grade system was shared with the neighboring Maasai, with whom the Kikuyu traded, warred and sometimes intermarried (July, 1970) (see Chapter 3, Section 3.11.1, Population, Kikuyu and the Mau Mau and Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya).

1.7.2.3 City-states of East Africa - links to the Middle East

“As was true in Europe, Asia, and the Americas, not all African peoples lived in large kingdoms. There were a variety of social and political systems in Africa. In addition to the large kingdoms, there were smaller centralized political units, some of which historians call City-states since they were made up of large urban-like areas. These geographically smaller states shared much in common with the larger African kingdoms. The primary difference was size. The system and practice of governance that centralized power in the hands of a king and a supporting caste of political advisors and elites in these smaller kingdoms was similar to that of larger kingdoms. Moreover, control of trade and a strong military were also important factors in the development and maintenance of these smaller states. Oyo, Ife, Illorin, and Ibaban are examples of West African city-states. Sofala, Kilwa (Figure 1.1), Malindi, Mombasa, and Lamu are examples of East African city-states” (ANON, 2002a).

Arab geographers knew the coast of East Africa as the land of *Zinj* (July, 1970; ANON, 2002d), a word referring to the black colored natives' skin. Around the year 500 AD, the first Arab traders docked at this corner of the Indian Ocean and launched their long colonization process during which they introduced their culture, their mosques, their religion, and their bazaars.

It is believed that Arab trading posts at or near local African towns in time became Arab-Muslim kingdoms established over African royal houses, which slowly became Islamicized through the influence of Arab merchants (July, 1990).

“From the 9th century AD, cities like Pate, Lamu and Malindi were founded, giving rise to a new civilization, which was Bantu-Arab in origin but developed its own personality, including a new language. Swahili or Kiswahili was born as a blend of the Bantu grammar and the Arab vocabulary, and was initially written with Arab characters. The word Swahili appears to be a derivation of the plural of the Arab term Sahel (edge - of the Sahara), meaning, 'coast'. Centuries later, adapted to the Latin alphabet, it would

become the most widespread language in East Africa” (ANON, 2002d).

A major trading center in East Africa from the 12th century AD was Kilwa (Figure 1.1) (just south of Mafia Island and modern-day Lindi, Tanzania), which gained control of Sofala (off the mouth of the Zambezi River of modern-day Mozambique), linked to Great Zimbabwe (described below). Its control extended to Pemba Island off modern Tanzania and included Zanzibar and Mafia Islands. Between Kilwa and Mogadishu (Somalia) there were 40 coastal towns sustained by agriculture and commerce based primarily on ivory (e.g., island of Mombasa, Malindi, fortified islands of Pate and Lamu). In addition to ivory, timber, pitch and civet musk were exported, while imports included some foodstuff, some pottery and cloth. Slaves were not a commodity at this time. (July, 1970).

Eventually, the following developments took place:

“Traders found here fertile grounds for their business, exploiting the wealth of this virgin territory. The Arabs started organizing their caravans to the inner lands, capturing natives to be sold as slaves, giving birth to a form of trade that would thrive for centuries. The routes so defined by the Arab tradesmen would remain as the only paths inland that would even be used by the first European explorers who would arrive 100s of years later.

The maritime routes of this nascent commerce linked the East African coast with the Indies. Textiles and other manufactured products brought by sailors from the Arab countries, from India or China were exchanged for iron, ivory, gold or slaves, promoting this region to a flourishing development that would persist without interference until the arrival of the Portuguese ships. The Persians, who arrived in the coast pushed by the monsoon winds in their lateen dhows, also used these commercial flows. In the 14th century AD, the Persian traders founded the city of Mombasa. The Chinese and the Malaysians visited these shores as well, using the routes established in this golden age of East Africa” (ANON, 2002d).

In a few short years, from 1502-1509 AD, the Portuguese subjugated the coastal city-states of East Africa: Kilwa in 1502 AD, Zanzibar in 1503 AD, Sofala in 1505 AD, Lamu and Pate in 1506. They finally also defeated a combined fleet of Egyptians, Arabs and Persians in 1509 AD. The succeeding Portuguese occupation resulted in a passive resistance on the coast and interior reducing the flow of gold to a trickle, with Sofala barely meeting expenses. The overall Portuguese trading losses during its 200 year long control of East Africa ran as high as 40% over revenue. When Turkish power attempted to infiltrate the East Africa Coast at the end of the 16th century AD, they were welcomed as liberators. By the middle of the 17th century AD, Omani sultans had dislodged the Portuguese from Muscat (Middle East) and were raiding East African ports, with Fort Jesus (Mombasa) falling to Oman in 1698 AD. This ended 200 years of Portuguese occupation north of Cabo Delgado (northern Mozambique) that had sought and yet failed to obtain economic exploitation through military control, as this ended up undermining commerce. If this was not disastrous enough, around 1580 AD a Bantu group, the cannibalistic Zimba from Malawi, arrived at the Portuguese trading posts of Tete and Sena, killing and eating every living thing, including people. The Zimba arrived in Mombasa by 1589 AD and were finally subdued near Malindi by warlike Segeju people moving down the coast (July, 1970; Pikirayi, 2003 *In: Beinart & McGregor, 2003*).

The Omani proved to be no better masters than the Portuguese. Civil war in Oman resulted in Pate, Malindi, Pemba, Mafia and Kilwa revolting by the 1750s AD, while Mombasa and Kilwa considered themselves as independent states. By the mid-1780s AD, Oman was left with only a fragile control over these city-states (July, 1970).

It was “at this time that slaving became important”. Slaving had never been an integral part of the Portuguese era. However, by the middle of the 18th century

AD, the Dutch from Cape Town were taking slaves from Madagascar and Mozambique, soon to be joined by the French, who needed plantation labor on the Indian Ocean islands of Ile de France (Mauritius) and Bourbon (Reunion). In 1776 AD, a French trader, Captain Morice signed a treaty with the Sultan of Kilwa to supply 1,000 slaves/year. By 1790 AD, the French were taking 1,700 slaves/year from Kilwa. By 1811, Zanzibar had become the chief center for coastal trade with 6,000 – 10,000 slaves annually going to Mauritius, Muscat and India along with ivory, rhinoceros horn, etc. Half of Zanzibar's annual tariff revenue went to the Sultan of Oman. Eventually, Sultan Sayyid Said would move his Omani throne to Zanzibar to take advantage of the wealth coming off the African Continent (July, 1970).

The slave trade was the cause of the dissemination of African natives throughout the Indian Ocean shoreline and its areas of influence. In Mesopotamia and even in South China, African slaves were present from 800 years ago. In addition, the presence of the new settlers left a lasting impact along the Kenyan coast; today, some 40,000 descendants of those first Arab traders still inhabit this region. Conversely, the influence of the East Indies on the interior of Africa was scarcely significant regardless of the fact that over the past two thousand years there have been small settlements along the coast (ANON, 2002d).

1.7.3 Southern Africa

1.7.3.1 Khoisan-speaking groups (click language)

Prior to the arrival of the Bantu, a hunting and gathering people, the Bushmen/San lived all over Southern Africa, which at the time was flush with game and fruit-bearing trees, bush and shrub. Somewhere north of the Zambezi River, the southward Bantu migration split into “human tributaries”. The arrival of the Herero and Ovambo along a westerly route, the Sotho-speaking people through the central areas from Botswana, Lesotho, the Free State, Limpopo, Northwest and Northern Cape Provinces in South Africa, the Tsonga in Mozambique, the Venda in the Zoutpansberg of South Africa, and the Nguni [Zulu, Swazi, Ndebele (Matabele) and Xhosa] along the eastern coastal belt pushed the San/Bushmen out of their traditional hunting grounds. Those who resisted these advances were butchered, their women becoming part of the conquering chief’s harem (Becker, 1974). Smith (1992) places the first indication of cattle in the Transvaal Highveld (South Africa) in the 5th century AD (400-450 AD) and estimates that a significant numbers of early iron using people and their cattle were present in the Transkei (southeastern South Africa) by the seventh century AD (Smith 1992).

In some cases agro-pastoralists would have developed amicable relations with San hunter-gatherers, as was the case between Pygmies and farmers on the forest fringes. Given a choice, hunters would not have become herders, while agro-pastoralists would have been reluctant to give up breeding stock, except maybe small stock. Thus in such instances (adoption of small stock), hunters would have given up their traditional way of life to become poor agro-pastoralists or in some cases developed a master-servant relationship with the agro-pastoralist (Smith, 1992).

In the Western Cape, some traditional hunter-gatherers now called Khoi/Khoikhoi/Hottentot became herders with cattle and small stock, while those who remained hunter-gatherers, the San/Bushmen tended to become clients, attaching themselves intermittently to herders as suppliers of food or becoming permanently dependent on a patron. The San were valued as watch-dogs and trackers for the Hottentot against raiding by other pastoral peoples; in essence, they became mercenaries during wars between the Hottentot/Khokhoi nations (Smith, 1992).

Diamond (1997) believes that malaria, which moved southward with the genetic resistant Bantu (sickle cell)¹³ and their farms that provided breeding habitat for the mosquito vector, had a major adverse impact on San populations who had no immunity to this disease. With the coming of whites in the 1650s AD, San were decimated by further epidemics of measles, small pox and other diseases, as well as hunted down like vermin. Where the Bantu and Khoi did not marginalize the San, collision with inland moving Dutch/Afrikaner Boer trekkers helped push the last remaining hunter-gatherers of Southern Africa into the hostile regions of the Kalahari Desert. By 1800, the Bushmen were virtually extinct, with the exception of the harsh inhospitable deserts where remnants of their hunting and gathering way of life continued until recent times (Becker, 1974). In the 21st century, modern bore holes (see Chapter 6 on boreholes), conservation policies [Chapter 3, Section 3.9.2, Eco-Genocide and the San of the Central Kalahari Game Reserve (CKGR), Botswana] and government policies favoring pastoralists, often elites, jeopardize the remnants of this once vast extensive decentralized society.

¹³ Heterozygote sickle cell carriers are much more resistant to malaria than those with just normal hemoglobin, this condition developing among African populations living in areas where malaria was endemic.

1.7.3.2 Great Zimbabwe – Shona Kingdom

It is said that the Shona originate from the Karanga, who came from the Congo basin (July, 1970).

“The Shona were most likely the first Bantu-speaking people in the area, displacing the Khoikhoi (Bushmen) and possibly some central Sudanic inhabitants. By the 10th century AD, Shona speakers had become the most numerous people between the Zambezi and Limpopo rivers, though they were by no means the only inhabitants. The Shona comprised a mosaic of disparate chieftainships, similar in their languages and livelihoods - based on a combination of agriculture and animal husbandry - but with a diversity of religious beliefs and customs. Although all were patrilineal, their political organization and means of succession varied considerably. Familial and dynastic competition was common, though there were no standing armies and major conflicts were few. After 1000 AD, centralized states began to emerge among the Shona. It was not until the 14th century AD, however, that these empires became distinguishable, as they competed for trade in gold and ivory with Arab and, later, Portuguese merchants” (ANON, 2002e).

Major empires include Mapungubwe (1050-1270, AD), Great Zimbabwe (Mwanamutapa, 1290-1450 AD) and Changamire (a break away kingdom from Mwanamutapa, 1450-1820 AD) on the Zimbabwe Plateau, as well as Thulamela and Torwa (ANON, 2002e; Pikirayi, 2003 *In: Beinart & McGregor, 2003*).

“Located in the south central African nation of Zimbabwe are the ruins of monuments and cities built of stone. These ruins extend to a radius of 100 to 200 miles (161-322 km), a diameter almost as great as the entire nation of France. Believed to have been built by southern Africans about 600-1,000 years ago, they are evidence of a thriving culture. Until recently, the ruins were believed by Western historians¹⁴ to be the remains of a ‘mysterious white race’ in the heart of

¹⁴ Such as Bent (1892), Hall and Neal (1907) and Gayre (1972). They argue that Great Zimbabwe may have been the work of Sabaean Arabs that many consider white but Diop (1974) considers to be of mixed blood and heavily influenced by Ethiopia.

Africa...It is now generally accepted that the ruins of Great Zimbabwe reflect the culture of the Shona peoples, a Bantu-speaking ethnic group, who reside in the region today. The name Zimbabwe comes from the Shona. Roughly translated it can mean ‘Houses of Stone’ and is associated with ruler ship” (The Sankofa Project, 1999).

Ancestors of the Shona, contemporaries of the Mali Empire, occupied Great Zimbabwe from the 13th to the 15th centuries. Most archaeologists agree that the Zimbabwe-type stone structures were intended to be indicators of status serving as dwelling places for the elite. The population of Great Zimbabwe, is believed to have been as high as 18,000 (The Sankofa Project, 1999). Diop (1974) argues that there were strong links and influence (e.g., architecture and religion) directly or indirectly between ancient black Ethiopia and the founders of Great Zimbabwe.

These ruins are believed to have been indications of the development of a large-scale centralized political authority in the 14th century AD associated with the arrival of the Mbire, a Bantu group with advanced metal and masonry skills migrating from Lake Tanganyika, who revitalized the Shona Kingdom, which by the middle of the 15th century AD experienced rapid territorial expansion. With Zimbabwe as a base, due to over-population and a shortage of salt, and urged by Arab traders, the Shona Kingdom extended its rule from the Indian Ocean to the Kalahari Desert and from the Limpopo River in the south to the Zambezi River in the north, gaining the praise as *Mwena Mutapa* (master pillager), or Monomotapa (Mwanamutapa) as called by the Portuguese (July, 1970).

Some archaeologists believe that Great Zimbabwe rose as a religious center. It is probable that it was a place where Mwari, the supreme Shona god, was revered and where cults of the *Mhondoro* (spirits of the ruling dynasty) flourished. It is also possible that Zimbabwe was a result of surplus wealth from the East African gold trade. By the 14th century AD, external trade existed between Great Zimbabwe and the city-states of the East Coast such as Sofala on

the southern coast of what is now Mozambique. Sofala was an important port where goods from India, China and the Islamic world (Red Sea, Persian Gulf) were imported and then sent into the interior, which in turn exported products from inner Africa. Gold was the most sought after export, but other exports, such as copper, also played a role. There was a sudden increase in building activity at the same time, as was the case in the cities on the East African Coast (The Sankofa Project, 1999). July (1970) estimates that as much as US\$ 1 million/year in trade flowed through Sofala in gold, ivory, amber, pearls, coral and copper.

“Between 1509 and 1512 AD António Fernandes traveled inland and visited the Mwanamutapa kingdom (Great Zimbabwe), which controlled the region between the Zambezi and Save Rivers and was the source of much of the gold exported to Sofala. Soon after, Swahili traders resident in Mwanamutapa began to redirect the kingdom's gold trade away from Portuguese-controlled Sofala and toward more northern ports. Thus, Portugal became interested in directly controlling the interior. In 1531 AD, posts were established inland at Sena and Tete on the Zambezi, and in 1544 AD a station was founded at Quelimane.

In 1560 and 1561 AD Gonçalo da Silveira, a Portuguese Jesuit missionary, visited Mwanamutapa, where he quickly made converts, including King Nogomo Mupunzagato. However, the Swahili traders who lived there, fearing for their commercial position, persuaded Nogomo to have Silveira murdered. Between 1569 and 1572 AD an army of about 1,000 Portuguese under Francisco Barreto attempted to gain control of the interior, but Barreto and most of the soldiers died of disease at Sena. In 1574 AD, an army of 400 men under Vasco Fernandes Homen marched into the interior from Sofala, but most of the men were killed in fighting with Africans. From about 1628 the Portuguese gained increasing influence in Mwanamutapa, and they became intimately involved in the civil wars that led to the demise of that kingdom by the end of the 17th century AD” (Columbia University Press, 2000).

A network of trading stations, missions, acquisition of land and mining rights turned the Mutapa king into a vassal to Portugal by 1629 AD. The size of

Mwanamutapa, the difficulty of communication and travel, as major rivers became barriers to the movement of armies, interference by the Portuguese and the absence of an orderly system of power transfer, resulted in the formation of breakaway states/kingdoms. Various governors distanced themselves from the ruling family and in this way, once the powerful king Matope passed on at the end of the 17th century AD, the breakaway Changamire kingdom, led by its governor Changa, conquered most of Mwanamutapa leaving only a small weak remnant in the Sena-Tete region. Ngoni invaders in the early 1830s AD put an end to the Changamire state (July, 1970)

McCann (1999) believes that Great Zimbabwe, like Mali and the Songhay Empires, occupied a zone which allowed it to withstand a harsh seasonality dominated by the movements of the Inter-Tropical Convergence Zone into the southern hemisphere. The Zimbabwe Plateau has a wet season from November to March followed by a dry season from April to October. Rainfall was sufficient to support crops like sorghum, millet and squashes in the elevated woodland savanna. It was estimated that one season in five suffered from drought and/or crop failure. This plateau area is uniquely tsetse fly free, and adjacent to lowland grazing areas that are seasonally free. Cattle are believed to have provided the major source of meat and milk, in addition to serving as a hedge against a shortfall because of poor rains or crop failure.

Some believe that the decline of Great Zimbabwe during the 15th century AD was in direct relationship to the decline of coastal cities (The Sankofa Project, 1999). Great Zimbabwe lost much of its power and importance due to a number of probable factors, including environmental degradation and a drop in the gold trade (McCann, 1999; The Sankofa Project, 1999). People living in Great Zimbabwe practiced agriculture and cattle herding, but the presence of too many people living in and farming one small area soon led to environmental degradation

(ANON, 2002a). There is thus a growing consensus that over-grazing, deforestation and drought in the 15th century AD were the primary causes for the empire's loss of status and power (Beinart & McGregor 2003). Eventually, the land was no longer able to sustain such a large number of people. McCann (1999) hypothesizes that shifting climatic conditions, resulting in an advancement of the tsetse fly belt, and/or a prolonged drought may have occurred, affecting the food supply and pasture needed to support a large plateau population. Pikirayi (2003 *In: Beinart & McGregor, 2003*) believes environmental changes combined with social and political events all contributed to the decline of this empire. These factors included drought and famine, Portuguese attempts at conquering the state in the 1570s AD, the Zimba "menace", revolts against the state in the early 17th century AD and wars between the Mutapa and the Portuguese, which ended in the 1630s AD. The Portuguese grabbed large areas of land, *prazos*; in the lower Zambezi. This resulted in hunger, famine and depopulation while undermining the authority of the ruling Mutapa. The Portuguese and their slave armies, the Chikunda, attacked local people, enslaved them, and deprived them of their property. Changamire Dombo organized an army expelling the Portuguese from the Central Plateau of Zimbabwe between 1693 AD and 1695 AD, thereby ending this threat. Between 1700 AD and 1750 AD, the Mutapa Kingdom shifted its base from the plateau towards the lower lying and harsher Dande and Chidima areas of the lower Zambezi. Pikirayi (2003 *In: Beinart & McGregor, 2003*) gives the reasons for this move as a search for increased security against the Portuguese and fighting among rival ruling houses, as opposed to over-population and environmental degradation.

"Great Zimbabwe was an early example of a state in this region of southern Africa with much political, economic, and military power. With its formation, social and political organization became more hierarchical. This involved a move from village level organization to a larger, broader social and political organization resulting in the Kingdom of Great Zimbabwe" (ANON, 2002a).

1.7.3.3 Thulamela

“The ruins of the ancient stone city of Thulamela were uncovered less than a decade ago in the Kruger National Park of South Africa's northern provinces. Thulamela, whose name means ‘place of giving birth,’ was built by the Shona people about 800 years ago. The city thrived between 1350 and 1650 AD and its people employed sophisticated mining skills, and succeeded in converting iron ore into carbon steel for use in tools and weapons, and traded along the Swahili Coast” (ANON, 2002e).

Others link this site to the Venda speaking people of area who in turn are linked to the Shona and Great Zimbabwe (Bunn & Auslander, 1998). This area is now part of the Makuleke contractual park (see Chapter 9, Section 9.6.3.7, Makuleke Contractual Park, South Africa).

1.7.3.4 The Zulu (Ngoni) Nation and its movement

It is believed that the fertile and relatively disease free environment of what is modern-day KwaZulu Natal permitted an uninhibited increase in population growth that by the end of the 18th century AD could no longer provide adequate pasture (July, 1970). As land became scarce, warfare changed from quasi-recreational into a strategy of conquest and survival. Poland, Hammond-Tooke and Voight (2003) attribute this change to increasing human populations, climate change (cycles of high rainfall followed by drought) and increasing contact with Indian Ocean commercial centers [e.g., whites in Lourenço Marques (Maputo) and the Cape Colony]. The *Madlathuli* (“They-eat-dust”) drought of 1800-1803 is thought to have possibly played a major role in triggering this change, decimating herds and crops while reducing thousands to destitution.

Young men were organized into military regiments based on age grades. Three Zulu federations arose: Ngwane, Ndwandwe and Mthethwa. Shaka was the bastard son of the chief of an insignificant group, the Zulus within the Mthethwa.

He displayed such military prowess that the Mthethwa chief, Dingiswayo, aided him to succeed his father as chief of the Zulu. While it is said that Dingiswayo instituted military regiments based on age grades, with manhood proven on the battlefield as opposed to circumcision, it took Shaka to refine this approach. Shaka took war from casual spear-throwing to hand to hand combat, using short stabbing spears, *assegai*, and a closure tactic, called the “cow-horn” that surrounded and encompassed the enemy. By the time Shaka became chief of the Zulu, the Ndwandwe had conquered Ngwane, who fled north to establish the Swazi nation. In 1818, the Ndwandwe defeated the Mthethwa, killing Dingiswayo. Shaka did not participate in this defeat (July, 1970).

Shaka retaliated in the “*Mfecane*” (“crushing”) combining his Zulu troops with that which was left of the Mthethwa army. He defeated the Ndwandwe and became the master of Zululand. Shaka quickly spread his territory through military conquest, limiting the authority of territorial sub-chiefs and ruling through his *indunas* (military leaders). Youth from all over the territory were required to do service in Shaka’s military barracks, where they were divided by age groups and trained, developing a bond that transcended ethnic differences. The result was cultural assimilation that served as a basis for the rise of the Zulu nation. The state relied on force to overwhelm the weak. In 1828 AD, Shaka was killed by his half-brother Dingane, but in the short decade, Shaka had created a nation (July, 1970). Shaka’s militaristic approach of absorbing other groups would eventually be felt as far away as southern Tanzania, where Nguni groups settled (Martin & O’Meara, 1995).

After being well on the way to subduing the Xhosa, the northern migrating land-hungry trekboers (Afrikaner/Boer) escaping British authority would clash with Nguni-speaking Zulu headed by Shaka’s brother Dingane in 1838 AD (Martin & O’Meara, 1995). They forced the Zulu to evacuate all territory below the Tugela River, which resulted in Dingane being unseated by his brother Mpande (July,

1970). In 1879 AD, after defeating the British at Isandlwana and killing Prince Napoleon, heir to the French throne, Cetewayo – Mpande's successor – was captured and imprisoned. He eventually pleaded his case to Queen Victoria but never regained his power, even though he had been promised. He died in 1844 AD, still fighting for his people. This marked the end of the Zulu nation (July, 1970).

Because of the *Mfecane*, factions of the defeated Ndwandwe clan of Soshangane moved northward (July, 1970; Parker, 2004) forming the Gaza Empire of Mozambique and the Shangaan people. In the 1820s AD, Soshangane moved to Delagoa Bay in what is modern Mozambique, and then inland where he came into conflict with another Zulu fugitive, Zwangendaba, in 1831 AD. Soshangane took over the area from the Zambezi to the Limpopo forming the Gaza Empire, in what is now Mozambique, which reduced Portuguese trading settlements to tributary status. The Gaza Empire became part of Portugal's African holdings by 1895 AD (July, 1970).

The Ngoni leader, Zwangendaba and his followers escaped a bad mauling by the Ndwandwe of Soshangane about 1831 AD and were forced into the Changamire Empire of the Shona where they were defeated again by another Nguni group moving north. Using Zulu fighting tactics, they devastated Changamire of Mashonaland and sacked Zimbabwe, crossing the Zambezi in 1835 AD, where they encountered strong but decentralized Lunda states. They moved through the land making use of a scorched earth policy against defenseless communities, passing to the west of Lake Nyasa (Malawi) to a point east of the southern tip of Lake Tanganyika. Here Zwangendaba settled creating Maputo, where he died in 1848 AD, 20 years after his great trek. With this strong leader gone, successions resulted in the Ngoni being broken into five groups. One group, the Tuta moved up the eastern side of Lake Tanganyika as far as the south side of Lake Victoria,

absorbing Nymawezi people and destabilizing the area, all of which aided the Arab slavers. The others dispersed west into modern Zambia and east into southern Tanzania (July, 1970) and Mozambique.

Meanwhile, the Mfecane pushed people out of one area and forced them into another: the Drakensberg Mountain area. Once such Sotho group, the Kolo, led by Sebetwane took off, seeing no future in the chaos and turmoil that ensued. They fought themselves through Tswana country, and after years of wandering ended up at the Zambezi River at Victoria Falls around 1838, where they subdued the indigenous Aluyi through intermarriage and created the Kolo Kingdom observed by David Livingston in 1851, now called the Lozi Kingdom (July, 1970).

Meanwhile, Mzilikazi and his Ndebele, also fugitives from the *Mfecane*, left behind a trail of destruction during their movements from 1821 to 1836 AD. They arrived in Matabeleland (southwestern Zimbabwe), once the domain of Changamire. During this trek, they settled near modern-day Pretoria for about ten years (near today's Hartbeestpoort Dam, at the foot in a passage through the Magaliesberg Mountains), eventually having to move due to threats from Dingane. Heading into Tswana country, they were attacked by Boers mistaking them for Griqua raiders, forcing Mzilikazi across the Limpopo. His organizational structure in Matabeleland was similar to that of Shaka, ruling through *indunas*. A class structure arose, giving privilege to direct descendants of the Ndebele over absorbed groups, which helped to preserve the language and culture. Mzilikazi's death was proceeded by a civil war in which his son Lobengula succeeded him (July, 1970); the latter eventually had to face the onslaught of the British under Cecil John Rhodes in the 1890s.

1.8 CONCLUSIONS

Africa is considered the “Cradle of Mankind” where modern humans were born. Pre-colonial Africa is the only continent where man and wildlife co-evolved and where massive extinctions of mega-fauna did not occur until about 350 years ago with the arrival of the European colonizers. A second wave of extinction can be associated with the human and livestock population explosion of the 20th century AD brought about by the colonizers’ introduction of modern medicine and veterinary care.

In pre-polonal Africa, the development of sedentary agriculture is believed to have been the basis for allowing the evolution of small-scale rural societies into complex hierarchical organizational structures in the form of kingdoms and empires with non-food producing groups such as artisans, *griots* and armies. These sophisticated kingdoms and empires had well-structured societies, systems of governance and armies as a means of protecting and expanding their realms of influence and controls over access and management of resources. Vast trade networks existed with North Africa, Europe, the Middle East, and Asia. The sale of slaves as part of this trade network may have been one of the most devastating and tragic events impacting African societies prior to colonialization and it is this activity, which first brought Africans into significant contact with the European world beginning in the middle of the 15th century AD.

The rise and fall of many of these empires is believed to have been due to a combination of over-expansion and loss of socio-political control, environmental degradation and climatic change, struggles over access to Africa’s wealth in natural resources, as well as the Islamization process, which took place through militaristic conquests under the armor of “*jihads*” throughout the Sahel.

Over-population and land hunger are believed to be closely tied to the southward Bantu migration out of the Sudano-Sahelian Zone (Bénoué Valley of Cameroon and Nigeria). They had a major impact on culture in East and Southern Africa. Their summer rainfall crops stopped them at the Fish River, South Africa, where they eventually came into conflict with the northward moving Boers, who were able to settle in the temperate climate of the Cape with winter rainfall crops brought from Europe. Likewise, over-population and land hunger are believed to have been the key to the Nguni migrations northward as far as Tanzania, leaving a wake of social destruction in their paths as they forced others to adopt their military culture of conquest or perish.

Chapter 2

2.0 TRADITIONAL NATURAL RESOURCE MANAGEMENT IN SUB-SAHARAN AFRICA

“Those who ignore culture are doomed to failure in Africa. Those who understand culture can find new ways to succeed...outside prescriptions only succeed where they work with the grain of African ways of doing things. They fail where they ignore, or do not understand, the cultural suppositions of the people they seek to address” (Commission for Africa, 2005).

“The slowness of the advances...in recognizing the contribution of indigenous peoples to maintaining biological diversity may contribute to the collapse of faunal and floral species that have been sustained by these groups for much of human history” (Langton, 2003 *In:* Adams & Mulligan, 2003).

“The white man thinks he understands the black man, but he knows him less. The black man thinks he understands the white man but he knows him less. The white man knows more about each other than the black man knows about each other” (Kibonde, *pers. comm.*).

This last statement refers to the lack of understanding between the Westerner and Africans, and at the same time points to the considerable similarity between the various Eurocentric cultures as opposed to the great diversity of cultures on the African Continent. These cultures, both within Africa and between Africa and the rest of the world, often do not understand each other and/or seem to be in conflict with each other. This chapter delves into how Africans and these diversities of cultures have traditionally managed their natural resources over the ages.

Pre-colonial Africa has often been depicted as a land of uncivilized warring savages in loin cloths and spears, with no knowledge of the environment or

insight into its sustainable use. Many believe that Europeans were required, with their modern wildlife, forestry, fishery and agricultural practices, Linnaean nomenclature and bureaucratic structures, to bring about the conservation and sustainable use of these resources. Many believe that without European intervention, Africa may very well have depleted its resource base in a process of self-destruction.

While Child (2004 *In: Child, 2004*) argues that Anglo-Norman protectionist game laws imposed on Africa under colonialism inhibited local institutions from developing, this chapter hopes to explain the relatively sophisticated systems that already existed/exist and are still for the most part being ignored as a means of integrating traditional value/management systems into modern conservation concepts. It might be better argued that colonialism and independence have impeded the evolution of these traditional management systems, ignored them and in some cases exterminated them, but they did exist prior to colonialism. In most cases, they are still present today, though often in a deteriorated state. However, they may be an important part of an “African solution”, if recognized and formally integrated into modern Western wildlife and natural resource management concepts. This could result in an Africanization of conservation that rural people can relate to, since as is evident in proceeding chapters “modern Western-driven conservation” has and is alienating the people of the subcontinent from what they have undertaken for 100s of years: the sustainable use of their resources and the conservation of biodiversity. May this chapter form the basis for better understanding these traditional management systems and hopefully spark debate and innovative thinking as to their utility even in 21st century Africa.

Chapter 3 discusses perceived perceptions by Europeans of Africans and their management systems and the disenfranchisement of Africans from their resources, especially wildlife, because of colonialism. Chapter 9 discusses the use

of traditional hunting guilds to manage a game reserve in Burkina Faso (Chapter 9, Section 9.8.9.1, Management of Comé-Leraba Game Reserve, Southern Burkina Faso), while in Chapter 11 a case study will be presented discussing how modern conservation is still ignoring traditional concepts, resulting in the eco-genocide of local cultures (Chapter 11, Section 11.11.7, Eco-Genocide in Southeastern Cameroon, the Forest People and *Dobi Dobi*, More Parks and Protected Areas).

In pre-colonial Africa, human and livestock populations were low and game populations were high. There was therefore less of a need to intensively manage wildlife than there is in the 21st Century.¹⁵

A risk-spreading strategy of using different resources from the same ecosystem avoided becoming too highly dependent on one single resource/environment. For instance, floodplains provided rich soils for recession agriculture, fisheries, pasture for livestock and wildlife, and waterfowl; while forests provided game, “*ignames*” (wild yams), honey and other wild foods, medicines, fuelwood and timber. In many cases, such as among the Mpiemu of the Sangha Basin, wild resources from hunting, trapping, fishing and gathering provided more and nutritionally better balanced food than cultivated resources (Giles-Vernick, 2002).

Capitalism and ownership of resources existed but unlike in the West where wealth is measured through an individual, ownership and wealth were controlled by a very strict social hierarchy through extended families and clans, often under the authority of chiefs, headmen, elders or religious leaders. While an individual could increase his status within society based on his skills in accessing and providing resources to the community (e.g., as a good hunter, farmer or warrior), individuals did not own land or resources. Rather they were borrowed from the

¹⁵ From Chapter 2 onwards, unless stipulated all dates and centuries are AD.

ancestors, and when a person died, they were returned to the community/ancestors. Anthropologists call these “Common Property Resources”, belonging to the community as opposed to the individual, or “Open Access Resources” belonging to everyone but the responsibility of no one but the state that resulted from the imposition of centralized management systems with the coming of colonialism (see Chapter 3) and the last 40 years of independence.

Child (2004 *In: Child, 2004*) defines “conservation” as a socio-economic process by which societies endeavor to manage resource scarcities and limit offtake within the biological capacity of the systems in order to sustain production. While not employing modern Western designed concepts such as measuring carrying capacity, maximum sustained yields, wildlife counting and indices as a means of setting harvest quotas, etc., pre-colonial Africans nonetheless used a number of management interventions. Natural resources were managed as “Common Property Resources” for the good of the greater community. Chiefs, elders and guilds, through the ancestors, carefully controlled access to natural resources including agricultural land, pasture, wildlife, tree products, fish, etc. Taboos determined protected species not to be hunted and by implication others which could be hunted (e.g., Bisa traditionally hunt buffalo, impala and warthog, but there was a taboo against “striped animals:” zebra, kudu, bushbuck) (Marks, 1984). According to Hakimzumwami (2000), in Central Africa, in addition to clan controlled territories, “cultural beliefs, taboos, respect to sacred sanctuaries, totems, etc., are believed to influence community behavior towards the use of natural resource, especially wildlife”. The ancestors and spirit world were consulted through chiefs (Hinz, 2003), spirit mediums and “master hunters” to assure a safe and successful hunt or harvest. Ultimately, by means of culture, taboos based on religion and traditional value systems, local rules and regulations enshrined in farming practices, land tenure systems and folklore, the indigenous Africans protected and conserved ecosystems and their associated biodiversity. In

addition, territoriality, mobility/migration, fire, harvest regulations (e.g., no harvesting of pregnant female or young), seasons, hunting guilds, etc. resulted in biological and sociological controls. Habitat manipulation was also (e.g., fire) employed to design landscapes needed to suit the various lifestyles of rural Africans.

Rules and regulations regarding access to natural resources were precise and codified, although not written down, and had been enforced since time immemorial. The result was sustainable exploitation of natural resources. This had been accomplished with no ecological purpose (e.g., maintenance of biodiversity) in mind, as we understand it, but out of a sheer instinct for self-preservation. Conservation of game animals and fish was necessary in order to provide for survival in the future. Ghai (1992, *In:* Fabricius, Koch & Magome, 2001) concludes that while in sparsely populated areas regulation over access to natural resources may have been minimal or non-existent, in most communities, systems existed to conserve resources and to ensure the equitable distribution of resources at the level of the household.

2.1 TRADITIONAL HUNTING AND WILDLIFE MANAGEMENT

“The story of the hunt will be tales of glory until the day when animals have their own historians”, old Zimbabwean saying *In:* Sogge, 2002).

“More likely, the top 1,000 hunters that ever lived have been lost to history, because the top 1,000 were illiterate. They were black Africans who probably never met a white man. Africa has produced thousands, no millions of native hunters, who would have embarrassed Neumann, Bell and Selous (Great White Hunters of the 19th and 20th centuries). This terrific trio could have walked into any village in remote Africa and hired a dozen hunters with more skill than they possessed” (Cacek, 2004)

When one reads the history of professional hunting in Africa, the landmark is normally considered the creation of the East African Professional Hunters Association in 1934 at the Norfolk Hotel in Nairobi, Kenya that started the era of the “Great White Hunter”. What most people fail to realize is that professional hunting existed for 100s of years among Africans, with apprenticeships that produced and still produce “Great Black Hunters” (Marks, 1976; Mariko, 1981). Tré-Hardy (1997) explains that in Francophone Africa, for generations and in every tribe, there was a hunting caste. Whenever and wherever able-bodied men were needed, this caste of qualified hunters organized the hunt and/or provided supervision to others. The organization was something akin to the political situation of the Middle Ages in Europe when the strong protected the weak and claimed the exclusive right to resources in the area. This implies that many hunters were also the leaders within their communities.

The “Great White Hunters” of yesteryear will confide in you that they were only as good as their trackers, the majority of whom were and are traditional hunters. To quote well-known Mozambican safari operator and author Adelino Serras Pires (2001), “My success was 80% due to my tracker (a traditional hunter), 10% to my driver and 10% to me. Every time I and my tracker found ourselves in an unfamiliar territory, it was a local hunter we would take on to help us locate the game” (Pires, *pers. comm.*). Pat Hemingway (son of Ernest) stated that to be fair, in Rowland and Ward’s trophy records, the names of the trackers should be placed before the owner of the trophy, since in most cases without them the trophy hunter would have gone home empty handed (Hecker, 2003). Anno Hecker (2003), who along with Pat Hemingway taught at Mweka Wildlife College in Tanzania, goes on to say, “I too felt quite often inferiority complexes when being faced with the art of hunting by those half naked savages”. Harry Selby (Woods, 2004) in an article about the East African Professional Hunters Association “Shaw and Hunter Trophy” for the professional hunter whose client

collected the most outstanding trophy says, “I myself never did (submit entries) and could have done so had I chosen. In many cases luck was the contributing factor in collecting the trophy, and the part played by the trackers and gun-bearers – often crucial – was not recognized – only the professional hunter got the honors”. Harry Selby is a living legend made famous in novels written by Robert Ruark, the “dean” of today’s professional hunters who retired from active guiding in 2000.

In the introduction of his book on traditional hunting in West Africa, similar to Marks (1976; 1984), Mariko (1981) states that “Hunting is a profession, a life” (Figure 2.1). Like Marks (1976; 1984), Mariko (1981) explains how totems, the spirit world, initiation rights and hunting guilds, which limited access to the profession and controlled-access by the chief and elders, played dominant roles in who would become a hunter and how, when and where wildlife could be accessed. Hunting was often the fabric that held their societies together.

MacKenzie (1997) provides the names of many African cultures to demonstrate how widespread and important hunting was to the:

- Hottentots and Bushmen collectively, Khoisan-speaking (click language) peoples of Southern Africa;
- Nguni/Zulu of South Africa;
- Sotho Tswana of South Africa;
- Griquas, a mixed race people of Tlhaping, Rolong and Kgwaketse of the Northern Cape, South Africa and today’s Botswana;
- Tswana of today’s Botswana;
- Ndebele and Shona of today’s Zimbabwe;
- Lozi and the Barotse in the upper Zambezi of modern Zambia;

- Gwembe Tonga of Zimbabwe/Zambia whose lives were destroyed by the Kariba Dam (discussed in a Chapter 7, See Section 7.9.1.3, Zambezi River);
- Luba and Lunda from Zaire/northwest Zambia;
- Luvale and Ndembu of western Zambia and the Bemba and Bisa of eastern Zambia descendants from the Luba-Lunda;
- Nyanja of southern Malawi and the Konde of the northern shores of Lake Nyasa (Malawi);
- Kamba, Wata (Waliangulu) of Kenya;
- The Nyamwezi of Tanzania, whose famous chief was Mirambo;
- Kikuyu of Kenya;
- Ndorobo of Kenya and northern Tanzania;
- Boni hunters in Tanaland of northern Kenya;
- Maasai of Kenya/Tanzania;
- Shambaa just inland along coastal Tanzania;
- Kimbu hunters of the Ukimbu Forests of central Tanzania;
- Lango, north of Lake Kyoga, the Jie (east of the Lango), Uganda; and
- Hamram Arabs of Sudan.

This can be supplemented by Mariko (1981) who provides examples from West and Central Africa including:

- Pygmies of the Central African Forests;
- Dozo, Donzow among the Mandingo, Malinké, Dioula and Palaga (Senoufo) mainly from Burkina Faso, Ivory Coast and Mali but stretching through Guinea-Conakry, Senegal and Gambia;
- Light-skinned blue-eyed Malaba bow hunters ranging from Senegal to the Nubian Desert and north to the Mediterranean;
- Mahalba of Northeastern Niger;

- Neolithic Caucasian Nemadi of Mauritania;
- Gow and other Zarmaphone Hunters from the *Boucle Du Niger*;
- Azna Hunters from Houssa, Niger;
- Tuareg;
- Toubou of Niger; and
- Mangawa, Daguirwa and Kanouri.

Musah, (2000 *In: Musah & Fayemi*, 2000) describes traditional hunters in Sierra Leone, the Kamajoisia (Kamajors) among the Mende ethnic group in the south, the Tamaboro or Kapra among the Temne in the northeast and the Knos and Kissis of the southeast (see Chapter 13, Section Chapter 13, Section 13.10.2.1, Sierra Leone, war and diamonds). Ibo (1994) states that in the Ivory Coast, traditionally the great hunters were also warriors. Hunters/warriors, like the Dozo (Chapter 5, Section, 5.7.4.4, Land reform and civil war in the Ivory Coast) have in modern times have become embroiled in fighting over control of Africa's natural resources and political power.

These are just a few of the many which these authors do not mention, such as the Hadzabe (WaTindiga) of Tanzania who speak a “click language” similar to the Bushmen; Shangan and Ndau of Zimbabwe/Mozambique/South Africa, the Baya of Cameroon/Central African Republic (CAR/RCA), the Lobi of the Burkina Faso/Ivory Coast border and the Kulango along the northern Ivory Coast/Ghana border.

Traditional African hunting methods (e.g., bows and arrows, crossbows, spears, traps, nets, snares, pitfalls, axes, assegais, clubs, poison and introduced muzzle loaders), compared to the technologically advanced firearms brought in by the Europeans, were relatively inefficient (Mackenzie, 1997) and under low human population numbers had little or no impact on game populations (Carruthers,

1995). While Africans may have controlled and manipulated the landscape to the benefit of livestock and agriculture, there seemed to have been a place for wildlife as a supplemental resource, while Europeans, with their modern firearms, devastated the game, bringing a number of species to extinction (see Chapter 3). This is a far cry from the perception of modern society, which is often the reverse of this scenario.

MacKenzie (1997) believes that for many Africans, hunting and gathering were constant indulgences, but their importance ranged from merely that of a pleasant pastime and a means of collecting additional dietary variation in a good year (plenty of rain and little disease) to that of a grim economic necessity in years of crop failure and livestock disaster. He also believes that hunting was “not just a function of necessity, but a preference involving excitement and romance, recreation and training” (e.g., courage, war, and leadership). Some individuals would be born with the “hunting instinct” in which the desire would be greater than that of his brothers. These individuals would do most of the hunting and/or be initiated into the hunting guilds and their rituals, secrets and taboos of the hunt, by which elders controlled access to wildlife in managing it for the greater good of the community as a “Common Property Resource”. Child (1995) estimates that 2-10% of any community will have the urge to hunt, regardless of whether it is a modern urban society or indigenous rural community.

2.1.1 Importance of Hunting to Maintaining Social Stability in Rural Small-Scale Societies

Due to the harshness of the environment, resulting in droughts, floods and cycles of agricultural pests, food security was/is addressed through a cooperative network of kin relations so that no one went/goes hungry (Marks, 2001; Hitchcock, 2003a). The importance of wildlife in the diet of Africans should not

be underestimated. The word for meat and wildlife is often the same word, *viande* in Francophone countries, “*nama*” in Hausa, *eyama* in Lingala of the Congos and *nyama* in East and Southern Africa. Likewise, the percentage of protein by weight of cooked animal flesh is much higher than in cooked vegetables (Peterson, 2003):

- 15-40% protein by weight in cooked red meat, fish and fowl;
- 2.5-10% protein by weight in cooked cereal and legumes; and
- No more than 3% by weight in cooked roots such as potatoes, yams, manioc, green leafy vegetables and fruit.

While nuts, peanuts and soybeans rival the protein content of animal flesh, their protein, except for soybeans, often lacks certain essential amino acids, the building blocks that make up protein, compared to red meat, fish, fowl and dairy products. Mixing complimentary vegetables such as wheat and a legume can help make up for this deficit. Of the twenty-some amino acids constituting dietary protein, all but nine can be synthesized by the human digestive system from simpler substances. Those nine are called “essential amino acids” that our bodies cannot synthesize and must be acquired from the foods we eat. The plant foods that provide all nine amino acids may not provide them in efficient ratios that allow their conversion to protein. While wheat and rice provide the nine essential amino acids, they are comparatively lower in the amino acid lysine and only contain half of what is found in animal proteins. Thus, only half of the protein from these grains can be used to assemble human protein. The rest, the unused and leftover amino acids are burned as energy like carbohydrates. Likewise, vitamin B-12 is lacking in a purely vegetarian diet that can result in the development of pernicious anemia and neurological damage. Thus for traditional cultures, especially in Sub-Saharan Africa, wildlife was and is a very important

source of protein (see Chapter 10, Section 10.3.4, CITES Cannot Stop the Bushmeat Trade) (Peterson, 2003).

The rites of hunting among many traditional societies that disturbed nature by killing required a counterbalance by acts of restoration and re-harmonization (Hinz, 2003). These requirements had to be fulfilled in order not to upset the basic social order and human's relations with their ancestors and nature. Thus, while the modern trophy hunter is an individual, the traditional hunter was/is part of a community for whom he hunted, who was keenly aware that he was disturbing the harmony of nature, had to pay by accepting certain restrictions (taboos) and who was obliged to make retribution to the ancestors in order to restore harmony at several stages of his hunting exercise (Hinz, 2003).

Among the Bulu of southern Cameroon, the rite of *sô* was the main initiation ceremony for a young man to become a 'true man' (*nya môtô*) and a real member of Bulu society. It involved a period of initiation, with those succeeding able to take part in the *sô* ceremonies. The *sô* is the name of the bay duiker (*Cephalopus dorsalis*) and the rite centered on the hunting and symbolic consumption of this animal, bringing together villages on a geographical, rather than clan base. Identified by ritual scars on the nape of the neck, forehead, jaws and forearms, the members of the *sô* came from many clans, united against misfortune and war. To make a pact the group would kill a *sô*, followed by each person cutting himself and placing the blood into the meal prepared with the *sô*. Each member of the pact would then partake in the meal making them 'brothers'. It would then be taboo to kill each other, regardless of what one of them said or did to the other, because it would be like killing yourself. This pact was called *avusô* (literally, tomb of the *sô*) (Solly, 2002).

Traditionally meat was for consumption of the lineage/clan group and not for commercial uses. Strict rules existed for the partitioning of the game among the community (Marks, 1976; 1984; Mariko, 1981; Ngaka, 2003; Thoma, 2002). Hunting and the collection of wild food were undertaken by the Hambukusu of the Okavango Delta only at a subsistence level to meet family needs. The non-commercialization of these resources assured a food reserve in times of famine and drought (Mangurunga, 2003).

For the Maasai, who co-existed with game, wildlife served as a protein reserve in times of extreme drought and hunger. In these rare cases, they ate only even-toed ungulates (e.g., buffalo, eland, Grant's gazelle, Thomson's gazelle, impala, and giraffe) (Mbarnoti, 2003).

Among the San also called Khwe (Khoe), Basarwa/Bushmen, hunting and gathering and the sharing of individual gains created a social network necessary for survival. The Ju/'hoansi San of Eastern Bushmanland were gatherers first and hunters second. Both men and women gathered bush foods that supplied 80% of their diet. Women usually gathered about three days a week. Hunting, and trapping, far less efficient, occupied men for an average of four days a week and provided 20% of the diet. Most meat and hunting produce was supplied by small animals such as steenbok, duiker and pig (most likely warthog), which were shot or trapped. Individuals distributed their own food, and gave and received their own property; this being the primary means that bound them into a larger society based on mutual obligation (Marshall & Ritchie, 2003).

Among the Ju/'hoansi and other groups there was a "concept of powers that links husband, wife, family, community and nature" in some kind of balance. Hunting, pregnancy and childbirth required extraordinary power. Roan, eland, gemsbok

and giraffe played an important role as *n!ow*, an inherent power that can be good or bad, that can bring rain or cold and is shared with human beings (Hinz, 2003).

As noted in Marks (1976; 1984) among the Bisa in Zambia, and Mariko (1981) in Francophone Africa, the distribution of meat from the hunt along with various taboos associated with the hunt, strongly tied the hunter to the community and the community to the hunter with regard to social responsibilities. This formed an important part of the network of cooperation that held these small-scale communities together and assured survival of their members. Wildlife was managed and exploited for the greater good of the community from which the hunter originated.

Among the egalitarian Baka Pygmy hunting and gathering society of Southeastern Cameroon, the Baka repress individualism and hierarchies as a means of maintaining harmony within the group. All game meat and other wild products are shared to the benefit of the Baka band or community (Nkombe, *pers. comm.*).

Because of the dangers of hunting, loyalty, honesty and chastity were required of the hunter and his apprentices, their wives and all the members of the family. All accidents caused by guns blowing up, falling, snake bites and animal attacks were associated with the hunter, or his wife and family breaking rules of conduct (Mariko, 1981; Hinz, 2003). Thus, as expressed by Marks (1976; 1984), the norms and morals of hunting helped reinforce the norms and morals of these rural small-scale societies.

2.1.2 Controlling Wildlife Distribution by Habitat Management

The Zulu of South Africa and the Ngoni (Zulu descendants) of northern Mozambique left unpopulated boundaries between chieftaincies as “wildlife reserves” (Mackenzie, 1997).

There is strong evidence that the pre-colonial East Africa of the 19th century was not the wildlife paradise that it is today, with about 25% of Tanzania set aside as parks and game reserves in the 20th/21st centuries (Kjekshus, 1977), nearly 40% by 2004 if all protected areas are combined (see Chapter 11, Section 11.10.6.3, Few success stories with the 10% factor). In East Africa, as elsewhere in the world, where people have expanded as farmers and cattle keepers, wildlife was gradually becoming extinct (Kjekshus, 1977). Burton (1860 *In:* Kjekshus, 1977) claimed that grass burning combined with organized hunting greatly checked the wild animals; “in the more populous parts game has melted away before the woodsman’s axe and the hunters arrows”. Dublin (1991 *In:* McCann, 1999) and Kassam and Bashuna (2002) were able to document a similar situation in Kenya.

In fact many of Tanzania’s well-known game reserves and parks of the 20th/21st centuries, including the Selous, Ngorongoro Crater, Serengeti, Lake Manyara National Park, and Lake Rukwa Game Reserve, had more people and livestock than wildlife prior to the 1890s (Kjekshus, 1977). The reasons for the changes that resulted in increases in wildlife in both Kenya and Tanzania are discussed in the next chapter (Chapter 3, Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya).

However, bush between settlements served as wildlife habitat (Kjekshus, 1977). For instance, Ford (1971 *In:* Kjekshus, 1977) mentions the massive bush clearing and wildlife eradication scheme utilized by Mzilla, one of the Ngoni (Nguni)

chiefs of northern Mozambique in resettlement of cattle and people in the Mzailizwe Valley in 1861. However, MacKenzie (1997) argues that they did leave certain areas for wildlife, indicating some sort of conservation ethic and utilitarian, cultural and likely spiritual value by the Ngoni for wildlife. The Ngoni were descendants of the Zulu who knew that *nagana* (bovine sleeping sickness) in South Africa was carried by wildlife. Their kings therefore organized large hunting parties to clear game so that cattle could be introduced (Mackenzie, 1997).

Wildlife remained rich in abundance in the bush (tsetse fly belts – vector of sleeping sickness), covering an estimated 33% of Tanganyika in the pre-1890s (Kjekshus, 1977) that was not contested for human habitation and existed between the larger tribal settlements (Kjekshus, 1977; Mackenzie, 1997). This is believed to have been the case over much of Africa, wildlife thriving in areas abandoned or never “developed” for agriculture by African civilizations.

2.1.3 Controlling Access to Wildlife through the Chief

In most African cultures, the chief, representing the ancestors and responsible for the survival of his people, controlled access to the land and its resources including wildlife (Marks, 1984; Mariko, 1981; Sithole, *pers. comm.*; Mangurunga, 2003). The *Chef de Terre* (land chief) controlled hunting activities along the Logone River of Chad (Dadnadjii & van Wetten, 1993) and still does so in southern Burkina Faso.

What today is Bénoué National Park used to be the private hunting grounds of the *Lamido de Rey-Bouba* (Fulani ruler), whose permission was required to hunt the area, defaulters being punished by traditional laws (Njiforti & Tchamba, 1993 *In:* Kemf, 1993).

Among the Oukwanyama, an Owambo (Ovambo) ethnic group in Namibia, the time of large scale hunting was determined by the king. When the dry season started, the king held the *oshipepa* ceremony during which he ate the first sorghum of the year's harvest, followed by a ceremonial hunt lasting one and a half to two weeks. By the time the royal hunt had finished most game had given birth to young and the people could begin to hunt. Similarly, among the Uukwambi [Owambo (Ovambo) group] the king started hunting and if someone wanted to hunt, permission was required from the king (Hinz, 2003).

Among the Hima, before somebody could hunt, the chief, on waking in the morning, would call his wife and send her into the bush to collect *ondombo* (*Poutoltia mixta*). The roots of this plant were cleaned, cut, watered and then put into a container (*Otjipurira*). The wife, chief and hunter tasted the substance, after which the chief went to the holy fire and addressed the ancestors, “*Please give this person luck to get one bull in the house. We are hungry*”. When the hunter returned with the bull, the horn was brought to the holy fire saying, “*Today, I have sent somebody away to hunt for a kudu bull in the mountains. I will not eat it in the mountain. I will do it here with my family*” (Hinz, 2003). Thus, the role of the chief in the hunt was to assure the success of the hunter and, in return, the survival of the small-scale rural society by ensuring that meat from the hunt was equitably distributed among community members.

Among the Tswana, the chief controlled wildlife and granted the right to hunt (Cullis & Watson, 2005).

Among the San, who have no chief, a *de facto* community head, normally the oldest man or woman within the core group was the guardian over the natural resources (Hitchcock, 2003a).

2.1.3.1 Royal game

Among a number of cultures, certain wildlife was reserved for the chief and one required special permission to hunt it. For instance:

- **Shangaan, Southern Africa.** Among the Shangaan, the lion and leopard, eland, kudu, sable and buffalo were royal game and one required special permission from the chief to hunt them. When one of the above antelopes was killed, it disturbed the land of the chief when falling, thereby polluting the soil with its blood. When one of these animals was killed, the half of the animal from the side that touched the ground must be given to the chief for compensation (Sithole, *pers. comm.*);
- **Bisa, Zambia.** Eland, lion, elephant, rhino and hippo were identified with the chieftaincy and when killed on a chief's land, parts of these animals had to be sent to the chief as a sign of allegiance (Marks, 1976; 1984);
- **Zulu, South Africa.** Leopard was royal game, and the skin was given to the chief/king who, in turn, compensated the hunter with a cow/ox. All tusks of hunted elephant went to Shaka the king (Ritter, 1955);
- **Tswana, Bechuanaland (Botswana).** In the 19th century, Tswana chiefs declared elephant, giraffe, eland and ostrich as “royal game” which the population could not hunt without permission. Lion skins, the breast of eland (*sehuba*) and the tusk of the elephant “nearest the ground” were destined for the chief (Hitchcock, 2001). Cullis and Watson (2005) list eland and gemsbok as royal game;
- **Mafwe, Caprivi, Namibia.** Hippo, eland, giraffe and buffalo were reserved for the chief. A hunter who killed one of these animals, under threat of punishment had to report the kill to the *kuta* (traditional court, advisors/*indunas*) before anyone could eat the meat. The chief would take

a piece of meat for himself and the hunter was allowed to keep the rest (Hinz, 2003);

- **Mayeyi, Namibia.** Hippo, buffalo, elephant, eland and giraffe were reserved for the chief (Hinz, 2003);
- **Gciriku (Kavango Group), Namibia.** Giraffe and hippo, “animals with long noses”, were reserved for the *hompa* (king) (Hinz, 2003);
- **Ondonga [Owambo (Ovambo) Group], Namibia.** Permission was needed to hunt elephant, the tusks going to the king. After the hunt, the hunter had to go to the king’s palace and sit at a special place where he was fed and women sang. Skins of leopards and lions were given to the king. When approaching the palace with the skins or tusks, the hunter blew a whistle along the way to inform the community he had killed an important animal (Hinz, 2003); and
- **Uukwambi (Owambo (Ovambo) group).** The eland was reserved for the king and its stomach used as a dress for the wife of the king (Hinz, 2003).

2.1.4 Territory in Controlling Pressure on Wildlife

In essence, in most cases the chief controlled a territory, and access to all resources within the territory.

However, while many hunting and gathering groups did not have chiefs, their access to wildlife and other resources was linked to clearly defined territories and cooperative actions to assure the survival of these small scale rural societies, “Remote Area Dwellers” (RADs) as some have called them in recent times (Hitchcock, 2002). Mobility, within these territories prevented over-utilization of wildlife and other resources, while allowing resource recovery during “fallow” rest periods. Wild foods found when gathering were probably more important than hunting. This territoriality and mobility within the territory was combined

with harvesting a diversity of resources, from game, to fish, honey, wild tubers and grasses, etc. so that pressure on the resource base for food was spread around and no one resource was rapidly overused.

2.1.4.1 Territory and wildlife management among the Dioula of southern Burkina Faso and northern Ivory Coast

Hunting areas were controlled by given villages and permission to hunt was required from the “master hunter” of that village, both by village-based hunters and outsiders (Traore, 2000). Ibo (1994) indicates this process among the Bakoué.

2.1.4.2 Territory and wildlife management among the Baka Pygmies and other ethnic groups of Cameroon and Congo

“In Central Africa, traditionally land is a sacred and common resource. It constitutes the mystic link between communities and their descendants. Despite new regulations, natural forest is informally subdivided into clan territories, which are naturally delineated. The clan respects others territory boundaries...The rights to use resources such as wildlife are underpinned by spiritual affiliations to land resources (forest, water, wildlife, etc.). Although members of society informally have equal right to use resources, traditional owners (generally a given clan) are those with primary spiritual affiliation and have therefore the ultimate responsibility to control resources in their territories” (Hakimzumwami, 2000).

Among the Baka, each lineage/clan group or village had a clearly defined territory. Everyone from this family had the right to use the “paths of their ancestors” and to exploit the resources around these paths. Only those Baka and Bantu who had been authorized by the *propriétaires de la route* or the owners of the route had the right to use these paths and thus the resources of an extended

Pygmy family (Schmidt, 1998). This implies, as with the Ju/'hoansi, that groups from outside the lineage and/or the Bantu/Pygmies ties had to obtain permission from the group to access the territory and its resources. Similar territorial management systems have existed for 100s of years and still exist among the Baveuk, Babouté and Bouté ethnic groups but may be jeopardized by the creation of hunting blocks and a national park (old Pangar Djerem Game Reserve) (Biko'o, *pers. comm.*) (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas). According to Peterson (2003) until the area along the Congo Brazzaville side of the Sangha River, which is now part of the Lake Lobéké/Dzanga-Sangha/Nouabalé-Ndoki “*Tri-National De La Sangha*” National Park complex, was turned into a logging concession for CIB (*Congolaise Industrielle des Bois*) in the 1960s [See Section 11.11.7, Case Study Bongo in the Congo (Brazzaville)], the Baka divided this area into nine separate hunting zones. Hunting chiefs (*chefs de chasse*)¹⁶ from each community met once every four years to determine practices and problems, consider if species or areas needed protection from over-hunting, and if necessary redefined the agreed upon boundaries of these traditional hunting blocks. This ended by the late 1980s, when Pygmy *chefs de chasse* stopped meeting because the bulldozing of roads by the logging company into the forests and the arrival of “professional hunters” (commercial poachers/hunters) from the outside, many from the Bakoulé ethnic group walked in and took over the Baka’s resources.

Claridge (1922) speaks of the Bakongo having clearly delineated hunting territories reserved for specific hunting parties (guilds) along the borders of present day Angola, Congo Brazzaville and the DRC. Fire was a key management tool, and anyone who abused the use of it was severely punished. Hunting took place in September (Claridge, 1922). Likewise, Hakimzumwami

¹⁶ Note: Baka traditionally do not have chiefs in the classical sense. This could have been “*tuma*”, (great elephant hunters) or something adopted from encroachment of Western or Bantu ideas.

(2000) describes that hunting in the DRC was traditionally regulated by a customary land manager, implying territory, who determined where and when the season of hunting, only for subsistence purposes, would take place.

2.1.4.3 Territory and resource management along the Inner Delta Of Niger

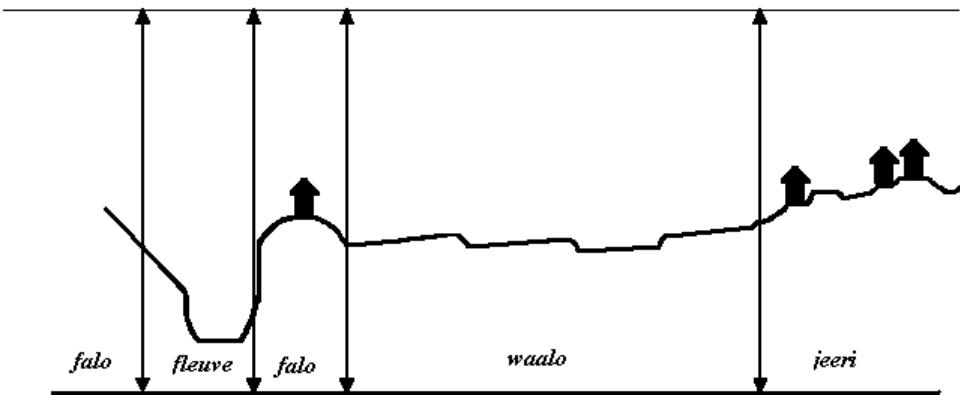

The Inner Delta of the Niger River is typical of Africa's floodplain ecosystems; its complex ecology is linked to traditional production systems of fisheries, recession agriculture, wild foods and pastoralism. These resources were managed under a common property management system during the 19th century under Fulani rule called *Dina*. The *Dina* was divided into a number of grazing territories allocated to loose Fulani clan groupings within which there were groups of subordinate farmers and more independent farmers; farmer/fishermen, and hunting and gathering fishermen (Moorehead, 1994). Exchange and cooperation between ethnic groups was common place. For instance the Peul (Fulani) provided meat and milk, Bozo provided fish, Songhay agriculturalists along the river provided grain, and Dogon living along the Bandiagara escarpment provided onions, pepper and grain, while Tuareg brought in salt (Smith, 1992).

2.1.4.4 Territory and resource management along the Middle Valley of the Senegal River

Boone (2003) describes a system that has extended into modern times, first left alone by the French and then by the newly independent country of Senegal through power sharing agreements. This area is known as the Fouta Toro after the Halpulaaren Foutanke Kingdom of 1515 made up of the Toucouleur/Fulb   (Peul/Fulani) (see Chapter 1, Section 1.4.5, Fulani, Toucouleur and Dioula Kingdoms, the Spread of Islam). The Toucouleur society was dominated by powerful lineages that controlled access to the floodplain. Following the

theocratic revolution against the Foutanke monarchs from 1778-1865, the Fouta was loosely united under a weak Islamic state headed by a ruler (*Almamy*), who was elected by representatives of several dozen prominent families. Under the *Almamyat*, the feudal Toucouleur society endured with a powerful aristocracy, controlling access to the floodplain in a high population density zone (Boone, 2003).

The land was broken into discrete territorial units or provinces known as *leydi*, long strips bisected by river (Figure 2.2) (Boone, 2003) similar to the *Dina* system along the Inner Delta of the Niger.

faalo (Pulaar): high damp banks (seasonal gardening, dry-season encampments)

fleuve (French): river

waalo (Pulaar): floodable basin, rich soil (flood recession agriculture, grazing)

jeeri (Pulaar): higher, sandier banks (rain-fed agriculture, villages, grazing)

Source: Redrawn Boone (2003, redrawn with permission from Barreteau, 1998:14) with permission from Cambridge University Press & Barreteau.

Figure 2.2: Cross-Section of Middle Valley, Senegal River showing makeup of *leydi* territorial units

The *leydi* under the *Almamyat* were managed as microstates by lineages of noble Toucouleur *Toroobé* who occupied positions of political power, extending on both sides of the river. The *Toroobé* provided provincial leaders including the

chef de territoire, village chief and *imam*. This elite controlled access to farming, grazing and fishing on the floodplain, as well as rainfed agriculture (Boone, 2003) and certainly wildlife.

This system of management was part of a strong caste system. Freemen or *RimBé* were at the head of a caste system, with a religious aristocracy from this group, the *Toroobé*. Next in the caste system were artisans including iron workers, leather workers, weavers, fishermen, woodworkers and oral historians (*griots*). At the bottom of the caste system were slaves, whose positions were transmitted by inheritance with no property rights. The oligarchy cultivated some land but mostly lived off land rents and tithes received in return for access to land (Boone, 2003).

2.1.4.5 Territory and resource management, the Ju/'hoansi of Eastern Bushmanland, Namibia

The following is believed to apply equally to the Ju/'hoansi of Ngamiland, Botswana: traditional geographical boundaries were more socio-cultural than political. The Ju/'hoansi (San) of Eastern Bushmanland, Namibia did not have chiefs, resource wealth or control of property in their society, which was based on equality. Individuals distributed their own food and gave and received their own property; they thus bound themselves into a larger society based on mutual obligation. Gathering and hunting were individual, not group activities; cooperation came in men tracking once an animal had been shot. *N!ore* (territory) is a Ju/'hoansi word for a named place with a source of water and resources of bush foods in its immediate neighborhood (Marshall & Ritchie, 2003).

All their rules of land ownership and residence were based on fixed, predictable resources of bush foods and water, (ultimately on permanent water,) with the

result that the association between Ju/'hoansi groups and the places they inhabited was extremely stable and ecologically communal (Marshall & Ritchie, 2003). Access to resources in the *N!ore* were inherited from one's parents or gained through marital/other ties (Hitchcock, 2000a; Marshall & Ritchie, 2003). Thus, permission to hunt within the *N!ore* was along lines of kinship, historical association and specific local resource availability (Hitchcock, 2003a; Thoma, 2002).

2.1.4.6 Territory and resource management, the Ju/'hoansi, Ngamiland, Botswana

The following is believed to apply equally to the Ju/'hoansi of Ngamiland (Eastern Bushmanland), Namibia. Among the Ju/'hoansi of Ngamiland, Botswana, individuals, often elderly persons, both males and females were recognized as having long-standing rights to an area and were considered land managers, or, as they are known *kxai kxausi* or *n!ore kxausi*. A territorial owner was sometimes called a *k@xau n!a* by the Ju/'hoansi. This individual may or may not have been a group leader. In some cases, he or she was considered to have a certain amount of authority and responsibility for organizing and managing natural resource related matters, but it should be stressed that they could not make formal decisions without seeking public consensus in the group (Hitchcock, 2003b). The same terms and processes existed for the neighboring Kung Bushmen in Tsumkwe West (old Western Bushmanland) (Arnold, *pers. comm.*). As Marshall (1976 *In:* Hitchcock, 2003b) notes, what a *k@xau n!a* did was to give focus to the ownership of the resources. This position was passed from one generation to the next, and thus it expressed continuity of ownership from generation to generation.

A non-resident group seeking access to a N!ore, would approach the *n!ore kxausi* who made their decisions on the basis of whether or not it was felt by the community that there were sufficient land and resources available to sustain additional people. Such decisions were usually taken on the basis of public consensus. The criteria used in reaching decisions included whether or not the individuals seeking access to the local group's land had either kinship or marital (affinal) ties to the group. There were sometimes conditions under which other groups were not allowed to enter an area, such as when there was a severe drought in progress or when key local floral resources such as mongongo nuts were scarce (Hitchcock, 2003b).

2.1.4.7 Royal hunting reserves

Game reserves in Sub-Saharan Africa, limiting access to game, existed well before the arrival of the white man:

- In the 1820s, Shaka created a royal game reserve in the Umfolozi District of Zululand, which was out of bounds to commoners (Carruthers, 1995; Fabricius, *et al.*, 2001). This was in the region of the modern day Hluhluwe Game Reserve and acted as a preserve for the ruling political and military class (Murombedzi, 2003);
- Mzilikazi set up a game reserve in Matabeleland called Maduguza, west and northwest of his capital, Bulawayo, where no one was allowed to kill without the king's permission (Murombedzi, 2003).
- The hunting Shangaans of the southeastern lowveld of modern Zimbabwe set up a royal wildlife preserve in the area around present day Gonarezhou National Park (Murombedzi, 2003);
- The *amaSwazi* (of Swaziland) also had royal hunting reserves (Fabricius, *et al.*, 2001); and

- The Fulani King, the *Lamido de Rey-Bouba* had a royal hunting reserve in which permission was required from the *Lamido* to hunt. This reserve was situated in what is today's Bénoué National Park (Njiforti & Tchamba, 1993 *In: Kemf, 1993*) (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas).

2.1.5 Mobility as a Means of Managing Natural Resources

In essence, mobility served, similar to fallow in agriculture, to rest an area over a certain period of time, giving the wildlife populations and other resources an opportunity to recuperate through growth and reproduction, thus assuring sustainable harvests.

2.1.5.1 Mobility and resource management, the Ju/'hoansi, Nagamiland, Botswana

Hitchcock (2000a) discusses a number of practices among the Ju/'hoansi of both Namibia and Botswana that demonstrate how they actively managed their resources. The Ju/'hoansi stopped foraging in an area if they felt that there were too few resources, allowing the area to rest so that the plants and animals could rebound. This might be considered a form of fallow management. They sometimes used a kind of hunting and gathering zone rotation strategy, going out in different directions from their residential locations over time. The growth of desirable plant species was encouraged by burning the bush; some people referred to this strategy as "Bushman plowing". People also transplanted desirable plant species such as morama (*Tylosema esculentum*), which produce both nuts and roots that are highly nutritious. One reason that wild plant populations in the /Xai/Xai (Botswana) region remained healthy was that the Ju/'hoansi exploited a

large number of them, over 120 species so that if certain species started becoming scarce, they could shift their emphasis to other species, allowing the pressured species to recuperate.

2.1.5.2 Mobility and resource management, Tyua Bushmen of northeastern Kalahari

The Tyua Bushmen populations of northeastern Kalahari, Botswana, had a kind of tethered land use system in which groups remained close to permanent water during the dry season and ranged out over the landscape during the wet season, when they gathered berries, nuts, and bulbs and engaged in hunting and trapping. A major factor affecting residential mobility in the northeastern Kalahari was the presence of other groups in the habitat. Among the Tyua, long-distance cooperative hunts included large numbers of hunters, sometimes as many as 30. Long-distance hunts were carefully organized with the assistance of a *dzimba*, a man particularly skilled in hunting and who was often called upon to take the lead in long distance hunts. In essence, he played the role of a leader/chief, but was not a chief. Women and children often accompanied men on these long-distance trips to provide a labor force for processing the various animals killed by the hunting party. These cooperative hunts were reminiscent of the communal hunts organized by Tswana chiefs. Environmental monitoring and information sharing were employed by Kalahari populations in an attempt to reduce the degree of unpredictability and risk (Hitchcock, 2003a).

2.1.5.3 Mobility and resource management, Baka Pygmies of Southeastern Cameroon

The Baka Pygmies of Southeastern Cameroon are a hunter gatherer culture, typically divided into bands of extended family numbering 40-50 persons per

group over a vast territory. They have few material needs other than hunting implements and cooking utensils. Their society is simple and flexible and membership within a band is not definitive (Nkombe, 2004). Among the Baka Pygmies of Southeastern Cameroon, there is no chief, only leaders in the form of “*kobo*”, (elderly wise men), “*koboa wose/kobowossé*”, (elderly wise women), “*tuma*”, (great elephant hunters) and “*Nganga*” (healers) (Schmidt, 1998; Nkombe, 2004).

Mobility of the Baka, like many hunting and gathering groups, prevents over-exploitation and permits the forest to renew itself (Schmidt, 1998; Nkombe, 2003). Most hunting took/takes place within short distances of the village. Hunters were/are, for the most part, men of between 18 and 55 years of age, who occasionally use guns but mostly caught/catch their prey with steel wire snares (Abilogo, Mondo, Logo & Nguiffo, 2002). Traditionally, they hunted with crossbows (*arbaletes* or *mbano*) and poisoned arrows, spears (*mbenga/mbomanya*), later adopting guns (Nkombe, 2003) and snares from the Bantu (Nkombe, 2004). For the Baka, these movements were considered a pleasure, not a constraint. *A go a bélé* (go for a walk) or *na sia bélé* (regard the forest), signifying the importance of the forest in their life (Nkombe, 2004). Schmidt (1998) describes the following seasonal movements:

- ***Mbanda.*** “Field hunts” near where they practice agriculture;
- ***Mombato.*** These are short forest visits of days-weeks, not far from their village to gather *ignames* (wild yams) or fish, and at times to trade forest products in order to be able to celebrate on occasions like Christmas; and
- ***Molongo.*** Long stays in the forest during the dry season (middle of November to middle of March) of 40 km or more from the village to escape the dust and heat of the sun during the dry season where they gather roots and wild mangoes, fish with weirs, search for honey and hunt

small game with lances, snares (pulled each morning) or crossbows with poisoned arrows.

These movements are not random but take place over clearly defined territories. Seasonal movements allow the natural resources to renew themselves. Nkombe (2004), a Cameroonian anthropologist initiated into the Baka manhood rites provides further divisions of movement/kinds of hunting, which he prefers to consider more as strategies for exploiting the forest for food than types of hunting:

- ***Sendo*** is a short walk from the village by men to undertake some hunting and collect honey, etc. as a means of meeting daily needs. Women and children may accompany their husbands;
- ***Noa*** is a short walk that women take into the forest (they are able to return to the village on the same day), individually or collectively and at times accompanied by husbands or fiancés, to collect food such as *ignames* (wild yams) and fish. If the opportunity presents itself they may hunt;
- ***Mombato*** is a visit of women to the forest lasting from a couple of weeks to months to gather and hunt mainly small game, which is consequently dried; and
- ***Maka*** is big game hunting far from the village lasting weeks to months by “seasoned” hunters with specialties to hunt specific species taking place before important ceremonies such as Jengui (Djengi or Forest God) manhood initiations, circumcisions *Beka*, and funerals. This hunt is preceded by a special ceremony, in which women dance the *yéyi oule yélé*. The *Maka* is the only hunt in which women do not participate, because of the dangers of hunting elephant, buffalo, gorilla, etc.

According to Nkombe (2004), traditionally *molongo* was not a type or strategy of hunting as *sendo*, *noa*, *mombato*, or *maka*, but a way of life, a permanent camp deep into the forest in which the entire Baka band took a “trip into the forest” to hunt and gather for months up to years; the primary *mode de vie* (way of life) of the Baka. Today, *Molongo* has become more a form of hunting (long-distance movement) than a *mode de vie* or permanent residence in the forest. *Mbanda* is similar to *molongo* but related to the Bantu *mode de vie* in the forest permitting them to practice agriculture away from the village without concern for possible crop damage by domestic stock, while hunting with snares and blackpowder muskets. Today, in mimicking the Bantu, the Baka also have *mbanda*, but practice more *sendo*, *noa* and *mombato* than agriculture as a mean of nostalgia for their former way of life which is rapidly disappearing (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas). The Baka are losing control over both their territories and mobility due to government policies, including buy-ins of Western designed and imposed parks and protected areas through the Global Environment Facility (GEF) program, as well as from forest fragmentation caused by logging companies.

2.1.5.4 Mobility and resource management, Ik of Uganda

The 56 km (35 mi.) wide Kidepo Valley formed their major hunting territory for most of the year and was known as “This is the place of God” given to them by their god *Didigwari*. Traditionally, the Ik were excellent conservationists. Since game, and even more so vegetation, could be exhausted quickly if a hunting band stayed in one place for too long, non-random mobility was essential to their lifestyles, as opposed to aimless wandering. Their nomadic movements were clear and precise depending on the time of the year, the rainfall/weather and the movement of game. Hunting and gathering, even in a marginal environment was

neither hard nor precarious. It was therefore possible to find fresh food daily. The Ik lived in sympathy with rather than trying to dominate (European mentality) nature. While for a farmer the results of a year's work can be destroyed overnight (e.g., elephant and other crop raiders, sudden drought, hail, locusts, etc.), the most the hunter can lose is what he can replace tomorrow. Over-hunting was considered a major crime and was only undertaken after long treks through non-productive territory. Hunting was a cooperative effort, with women and children participating in certain hunts (e.g., netting drives). Men were dominant only during the hunt, which had not only physical, but also supernatural dangers. However, it was the women who provided the bulk of and most reliable source of food from gathering and who had an equal say in where the group hunted and gathered. Mobility served more than economic needs; it allowed for constant realignment of friendships and work units, dissipation of disputes and a constantly shifting locus of authority so important to the egalitarian hunter. Family was a broad term, in which the hunter gatherer band with whom a person was associated was considered as family, a child considering any adult in the band as a parent and any age-mate as a brother or sister. The “environment invariably provided the central theme” that held them together, giving them a sense of common identity; it was a hub around which their life evolved and it provided all the necessities such as food, shelter, clothing and spiritual existence (Turnbull, 1972). Taken from this environment, the Ik as a culture would no longer exist (Chapter 3, Section 3.9.3, Eco-Genocide and Ik, the Mountain People).

2.1.6 Hunting Guilds as a Means of Controlling Access to Wildlife

Wildlife was anything but an “Open Access Resource”. Access to wildlife over much of Sub-Saharan Africa was carefully controlled through hunting guilds. Hunting guilds (Marks, 1976; 1984) or *confréries de chasseurs* (Mariko, 1981) have existed in Sub-Saharan Africa for 100s of years. Hunting was considered a

profession. Hunting guilds were widely spread, from Senegal to Niger (Mariko, 1981), among the Mossi, Dioula and Palaga (Senoufo) of southern Burkina Faso, northern Ivory Coast, and southeastern Mali; other Mandingo cultures of Mali through to Senegal; light skinned blue-eyed Malaba bow hunters traditionally ranging from Senegal to the Nubian Desert and north to the Mediterranean Sea, neolithique Caucasian Nemadi hunters of Mauritania; Gow and ethnic groups of Zarmaphone Hunters in The “*Boucle Du Niger*” (Inner delta of the Niger River) Mariko (1981), and as far South as the Bisa of the Luangwe Valley in Zambia (Marks, 1976; 1984) (see Section 2.1, TRADITIONAL HUNTING AND WILDLIFE MANAGEMENT). In some cases, as among the Baka Pygmies of Cameroon, it is not clear that there were true hunting guilds, though a rigid hierarchy of specialty hunters, played the same role by controlling access to various species as will be described below.

Not everyone could hunt, tending to be a male occupation (Mariko, 1981; Marks, 1987; Thoma, 2002). Hunters-to-be were identified through dream summons by the ancestors (Marks, 1976; 2001, DeGeorges, 1992a), and by natural prowess (Marks, 1976, Sithole, *pers. comm.*). Hunting was not necessarily hereditary (Mariko, 1981), though Bisa hunters in the Luangwa Valley of Zambia described hunting “‘as a disease passed on to them by their fathers, something in their blood’ ” and that they had no other choice but to hunt – “‘a calling from the ancestors’ ” (DeGeorges, 1992a).

In many cultures, becoming a hunter helped provide protein for the community and led to leadership roles within it (Marks, 1976, Personal observation of principal author among Dozo hunters June, 2003 in Comoé-Leraba Game Reserve and of Mandingo hunters in the *Zone d'intérêt Cynégétique de la Falémé*, Senegal in the 1980s). The hunter was often a warrior, hero and master of the supernatural in the bush and protector of villages against sorcerers (Mariko, 1981).

Marks (1984) estimates that traditionally only about 25% of the adult males in the Luangwa Valley were hunters. To become a hunter normally required apprenticing under an older “master hunter” and could take anywhere from three to six years (Mariko, 1981, Echappé, *pers. comm.*; Dozo Hunters of the Comoé-Leraba Game Reserve, *pers. comm.*).

The strength and invisible forces of the forest, mountain and soil mistresses were bathed in the continual mystery of nature (Mariko, 1981). In many cultures (Marks, 1976), learning to communicate with the ancestors was paramount. The apprentice hunter was taught not only hunting skills by “master hunters”, but also the secrets of the bush, rituals and taboos that would protect him from the spirits/shades and genies of the bush and game, and that would ensure a successful hunt (Marks, 1976; 1984, Mariko, 1981). Elders held the secrets of how to rest the spirit residing in dangerous game so that it could be hunted safely (Mariko, 1981; Marks, 2001). These elders also held powers to compel wild animals such as crocodiles, lions, elephants, hippos and buffalos to kill or maim individuals. This knowledge would be handed down to a select few, thus acting as a control over harvest pressure by the greater community (Marks, 2001).

Among the Bakongo there is an annual inauguration of the hunting season linked to spirits of the dead and “fairies”/genies who control the disposal of the game (Claridge, 1922). Hunters prepare communion to them at the spot where the dead body of a great hunter has been ceremonially washed, where his hair and clippings from his fingernails are buried, or at the hunter’s grave. This site of communion is called the bloody grave (*nkal’ a menga*) because it is here that the first antelope of the season is offered to the dead. The antelope’s bladder is taken out and filled with blood, which together with wine is poured on the grave. This potion is mixed with the soil and the resulting mud is smeared on the face of each

hunter, this act known as *yow' e toyi*. During the ceremony, all kneel to show unity, while a priest shaking a rattle summons the dead. This is followed by a prayer requesting meat, while a blood smeared drum is beaten and a song is sung:

“Let the man who trusts to luck
Not come, not come,
And let the man who has no pluck
Not come, not come”

The living and the dead have now entered into a fellowship that should result in good hunting. Poor hunting results indicate that the hunter is breaking certain rules or taboos and is not supported by the spirit world. Since an individual's action can impact on the group, implying some sort of “club” as it is called by Claridge (1922) or guild, the hunter can be fined and expelled from this group.

A hunter's success was dependent not so much on his own accomplishments or skills as on the spiritual merit in his lineage (Marks, 1976). Status among hunters was recognized by the medicines (*umuti*) they possessed that protected them and helped them overcome misfortunes. Some wild animals also possessed dangerous “spirits” or “shades” (Mariko, 1981; Marks, 2001). In West Africa, many of the most powerful hunters were also Moslem *marabouts* (priests), or worked with *marabouts* who prepared *gris gris* (amulets) and undertook other sacrifices to both protect the hunter and assure success.

Among the Baka Pygmies, these talismans are known as *simbo* and are worn on the back between the shoulders making the Baka invisible to the animal being hunted. There are *simbo* for elephants, gorillas, leopards, buffalo, etc. Another talisman is the *kudu linje*, a strap of skin from the otter. Among the Baka, one could be initiated into many specialties as one advanced. The ultimate was becoming the *Tuma* (elephant hunter), not because this type of hunting was considered any more noble than hunting a buffalo or leopard, both considered by

the Baka as dangerous, but because the elephant provided the most meat to the community, the ultimate goal of the hunt. In addition to dangerous game (elephant, buffalo, gorilla, and leopard) hunters, there were specialty hunters for snakes, turtles, excavators of animals who live in the ground, bushpig, etc. The Baka traditionally hunted with a spear or crossbow and poisoned arrows (Nkombe, 2003), considering the non-selective Bantu snaring for cowards (Nkombe, 2004). It is the *kobowosse*, or an elderly woman who initiates the hunter into his specialty (Nkombe, 2003; 2004).

Among the Baka, each hunting specialty has its taboos, and secrets for courage and success that the apprentice must learn. Training begins at the age of six to seven, when boys started hunting lizards and mice with crossbows. At the age of nine or ten, boys are initiated into manhood rites of the forest god *Jengui* and the girls into womanhood rites of the *Yeyi*. In essence, these are social guilds, revolving around hunting and gathering, which have the aims of controlling and managing the society and maintaining respect for its taboos and rituals. Such rites and social guilds could definitely be used as positive forces in the 21st century to conserve the forests, if given the opportunity (Nkombe, 2004). The boys can now become hunters. A man who does not have a hunting specialty or does not know how to collect honey cannot take a wife, so all men are hunters (Nkombe, 2004). It is a question of the level of specialization they attain, with the level of difficulty and danger increasing and the rank of *tuma* (elephant hunter) being the pinnacle.

Among the Mpiemu ethnic group of the Sangha Basin, they also had “master hunters” known as *tuma*. The *tuma* had no official authority to limit where, when or what other people hunted. However, his knowledge of “places for killing animals” and powerful medicines applied to his body to give him knowledge about the location and behavior of the game, allowed him to function as a “master hunter” in a guild. A village would give him gifts and he would take 2-3 hunters

with him to hunt, calling the village once they had harvested enough game. Thus the *tuma* exercised considerable influence over where, when and what a village hunted (Giles-Vernick, 2002). According to Biko'o (*pers. comm.*) an Mpiemu himself, everyone could hunt mainly with vegetative snares; today more and more steel snares are used. The *tuma* was mainly called upon to hunt large game and when game became scarce around a village. Biko'o also found it odd that, as described, only a couple of people from the village went on the hunt. Normally, meat is not shared communally between clans/extended families, but only within extended families within a village, who tend to hunt as a clan. According to Nkombe (also Mpiemu) and Biko'o (*pers. comm.*) there has never been a hunting/forest god named *Ntchambe Mkewombo* among the Mpiemu as mentioned by Giles-Vernick (2002). According to Nkombe and Biko'o (*pers. comm.*), the Mpiemu have only one God, *Ntchambe*. However, before being Christianized they believed in a spirit *Mekere*. The *Mekere* spirit served as an intermediary between *Ntchambe* and the Mpiemu, both guiding people in their hunting and helping to heal desperately ill people in the village.

As firearms became available, among the Bisa, and this is believed to be the case in many hunting cultures, the “master hunters” also controlled access to the wildlife by controlling access to firearms (Marks, 1976; 1984).

Among the Fulani of Rey-Bouba, Northern Cameroon, a chief hunter performed traditional rites to the gods before anyone could go hunting, controlling when and what could be hunted. To disobey him meant the likelihood of being killed by wild animals (Njiforti & Tchamba, 1993 *In: Kemf*, 1993).

Among the Wata of Kenya, boys began hunting with bow and arrow for small game. By ten years of age, they accompanied elders on hunts as porters, cooks and camp attendants. They often stalked after dangerous game with adults.

Manhood and acceptance into adult society depended on demonstrating hunting skill and bravery. After the first elephant kill, the hunter was considered a man, with ivory being part of the bride price necessary for marriage (Parker & Amin, 1983).

Among the Bakoué of the Ivory Coast, a “corporation” or guild of hunters under the management of a “great hunter” (*koussoupohiklagba*) from the guild strictly controlled hunting. Traditional hunters were good naturalists understanding animal behavior and reproductive cycles. Hunting was forbidden during the rainy season (*goudeu*), when wildlife dropped their young. Hunting was primarily a dry season activity. To signify the hunting season was over, the “great hunter” hung up (put away) his arm in public. The “great hunter” opened the season with a volley of gunshots (Ibo, 1994).

According to Oularé (*pers. comm.*), the origin of the Donso (Dozo) hunting guilds date back to the 1236 A.D. under the Mandingo Empire of Sundjata (Sundiata Keita [see Chapter 2, Section 1.4.2.1, Sundjata (Sundiata) Keita] and the *Charte Kouroukan Fouga* (The Charter of the Open Space – *Fouga*, On the Mountain - *Kouroukan*). This charter laid down 44 laws with nine traditional chiefs to enforce them. Article 37 of this charter says that “Fakombè is designated chief of the hunters. He is charged to preserve the bush and its inhabitants for the happiness of all”. The brother of the emperor, Manding Bory Keita was chosen to enforce this article and is seen as the “*Father*” of the Donso *confréries de chasseurs* (hunting guilds) (Oularé, *pers. comm.*). Each year at the opening of the hunting season a special rite is performed, Manding Bory *Sö* (Give to Manding Bory), in which a reddish cock, reddish goat or red cola nuts (red is linked to blood and the hunt) are sacrificed to have a good hunt. Among the Dozo of southern Burkina Faso, the apprentice hunter “*donso dewn*”, and his hunting are

controlled by the “master hunter” or “*donsofa, donso-koutogui* or *kalanfa*” as they are called among the Dioula (Traore, 2000).

In Guinea-Conakry, the hierarchy in the Donso hunting guilds among the Malinké are the *simbon* (equivalent to the “master hunter”, normally with about 25-30 years of experience, with dangerous game qualifications), *kalakoun* (a seasoned hunter), *kalati* (apprentice hunter using a blackpowder musket or shotgun) and *nantan* (a young hunter, 15-18 years old using *armes blanches* such as bow and arrow, club, spear, and maybe snares) (Oularé, *pers comm.*). According to Fairhead and Leach (2003), they are guided by *wa ton* (bush law) with regard to wildlife and its management. All are initiated at the hunters’ altar (*dankun*). Traditionally the “master hunter” forbids the killing of pregnant female duiker, a nursing female duiker and young (Traore, 2000). According to Oularé (*pers comm.*), the *donso tan* (hunting guild) forbids anyone to shoot unless the animal is clear of the bush and can be identified and to shoot a female with young. Each year, based on reproductive success and the game populations, the *donso tan* determines what and how many animals can be hunted. Each year a *Fetes des Dozo* or ceremony brings the hunters together to thank the “*dieux de la brousse*” or gods/genies of the bush (Traore, 2000).

Thus, limiting access to this profession, with its secret rituals tied to the spirit world, and to firearms, as well as the guild determining hunting regulations and seasons were key ways of controlling pressure on wildlife resources as a means of assuring a sustainable harvest of game meat. This was especially important for people living in areas where sleeping sickness prevented the raising of domestic livestock. It might be argued that traditional hunting guilds were not so different from Western hunting clubs that rent hunting properties and establish their own rules as to what can be harvested, in some cases being required to produce

wildlife management plans and quotas such as in France (Chantelat, Doumenq, Grange, Koumchasky, Le Pellec-Fonteney & Rebattet, 1989) and Germany.

2.1.7 Totems as an Aid in Wildlife Management

One of the key ways of controlling access to wildlife was through totems. These were animals attributed to a given lineage group which were taboo to kill. Totems are common throughout Africa such as among the Shangan (Sithole, *pers. comm.*). In West Africa (Mariko, 1981), examples include:

<u>Family</u>	<u>Totem</u>
Diarra	Lion
Keita	Hippo and crocodile
Diallo	Francolin
Cissé	Snakes, lion and leopard
Kanté	Monitor lizard, crocodile, chicken and white rooster, turtle

The totems of Kanté apply to all clans linked to blacksmithing and jewelry making. All Mandingo (Dioula) hunters consider the turtle dove as a messenger from the genies of the bush (Mariko, 1981).

2.1.8 Taboos as an Aid in Wildlife Management

Taboos were not only an indirect passive means of conserving some wildlife populations, but were also tied into maintaining social mores in small-scale rural societies where men might be absent from home for extended periods of time, while hunting. Shipton (1990 *In: Madzwamuse & Fabricius*, 2004 *In: Fabricius*,

Koch, Magome & Turner, 2004) states that taboos with regard to harvesting wildlife were only broken during famines, indicating that they might have served to conserve resources for emergencies.

Among the Shangan, sex before a hunt is taboo. If one has sex before a hunt, there is a risk that a female elephant with young will attack and kill the hunter (Sithole, *pers. comm.*).

Among the Kung bushmen a good hunter was fearful of eating or sleeping with his wife, because this would risk his “poison” (on his arrows) becoming cold, as she smelled of milk and *sā* (*buchu*) a herbal powder from the plant *Barosma betulina* (Hinz, 2003).

Among the Nama and Damara, hunters had to abstain from sexual intercourse the night before a hunt, ‘staying as pure as he was born.’ When an unmarried boy hunted, the mother had to abstain from sexual activities until he had killed his game. Wives of hunters were not allowed to quarrel, not allowed to do needle work with sharp tools, not allowed to make beds or sweep the house, nor grind the herbal powder *buchu* (*Barosma betulina*) – as all of these were symbols of the feminine life calming down male powers. Wives had to protect the fire of the hut, because the luck of the hunter died if the fire died. “Dirty water” had to be kept from the fire, it being dangerous for the hunter if soup or sugar spilled on the fire (Hinz, 2003).

Among the Tonga of the Zambezi River, everyone in the community had to partake in a special ceremony requiring them to be submerged in the Zambezi River before ivory could be sold (McGregor, 2003 *In:* Beinart & McGregor, 2003). The killing of female animals with young was forbidden. Hunting was to take place between May and September, but not just before the rains in

October/November, when killing an animal might leave young behind. According to the legend of the Nyaminyami, an animal/fish with a serpent-like head that controlled the flow of the Zambezi, the creature would appear and allow people to cut only the amount of meat from it that they could carry (use); this practice was called *njeka wa cheka*. Cutting (hunting and gathering) more meat than one could carry would result in it rotting before the person got home. Thus one only harvested from nature's resources what one needed so that these would not be exhausted, allowing the Nyaminyami to "regenerate flesh". In essence, this is the concept of "sustainable use" to ensure a perpetual supply of meat and other resources. All of this was guided by the spirit medium and chief, who consulted the ancestors. All hunters accounted for what they killed, by giving a portion of each kill to the chief; in essence a monitoring program. It was taboo to hunt before the meat from the previous kill had been finished. Failure to comply would result in one's children and livestock being lost to wild animals (Sibanda, 2004 *In: Fabricius, et al.*, 2004). Similarly, the Niger God from the 13th century Mali Empire (see Chapter 1, Section 1.4.2, Ancient Mali and the Mandingue [Mandinka/Malinké] Empire) was a turbaned figure in a colorful robe entwined by a serpent (Rosenblum & Williamson, 1987).

Among the Bisa of Zambia, game with more dangerous shades (*vibanda*)/genies included elephant, eland and lion, formerly associated with tribute to the chieftaincy, and were believed to cause mental illness of the hunter and his kin if specific rituals were not followed (Marks, 1984). This reinforced traditional social patterns through creating allegiance to the authority of the chief (Marks, 1976).

Both the Bisa (Marks, 1976) and many of the West African hunting cultures (Mariko, 1981) believed that the genie/shade/spirit of the animal resided in its head and that on killing certain species (e.g., elephant and buffalo) special rituals

were required following the hunt. Like people, animals have a spirit and when they are killed, the spirit leaves the body. A second spirit (a double) resides in the head of the buffalo, lion, leopard, certain antelope, warthog and hare, and can possibly haunt a hunter and give his wife, child or even the hunter mental health problems. Seeing blood or the eyes of game can cause nervous system problems for pregnant women (Mariko, 1981). Cutting off the tail of the dead game among the Dozo, allows the genie to escape (Echappé, *pers. comm.*), and in general among many hunting cultures in Sub-Saharan Africa shows ownership and proof of the kill when the hunter returns to his village or camp. When the author hunted elephant with the Baka Pygmies of Cameroon in 2001, on taking the elephant, he was initially not allowed to lift its ear for fear of death. Only after the tail was cut off, signifying ownership of the elephant and possibly as part of the ritual to allow the animal's spirit to leave peacefully, was he allowed to lift the ear and investigate the exit wound?

Linked to the evil/bad genies found in the animal's head was the Moslem belief in the "evil eye". The evil eye given to the hunter by a genie through a wild animal could make the hunter sterile or impotent. Among the Malhalbi of northeastern Niger, the belief was that lions and leopards were men that had been transformed¹⁷ as a result of having been given the "evil eye". The hunter feared duiker and dorcas and ruffifrons gazelles because they could bring bad luck with the "evil eye" (Mariko, 1981).

Among the Bisa, zebra, eland, bushbuck and kudu were linked to prohibitions and human sickness and thus rarely hunted (Marks, 1976). Also, in recent times, among the Bisa, hippo flesh was associated with leprosy and only consumed in times of famine (Marks, 1984). Bisa people believed that people with leprosy

¹⁷ The process is called transmogrification (suggests a grotesque or preposterous metamorphosis) or lycanthropy (the assumption of the form and characteristics of a wolf held to be possible through witchcraft) (Webster, 1989).

turned themselves into hippo after death, and that whoever ate hippo meat could suffer from the same disease. It was also a symbol of cultural unity against outside authority, since most government workers ate hippo flesh (Marks, 1976). Traditionally it was also forbidden for Zulu to eat hippo (Ritter, 1955).

Among the Kavango of Namibia, the hunter who killed an animal was required to step on it and sing a song of praise to the animal. In the case of dangerous game, hunters drank a mouthful of blood that seeped from the wound. The hunter cut off the tail and after covering the prey took it home and placed it in a location reserved for offertories, along with his weapons and then took a rest. Weapons placed upside down indicated he had only wounded but not killed. Certain parts of the animals were offered to the ancestors (Hinz, 2003).

The Mbukushu (Hambukushu) and Geiriku of Namibia were required to hang the head of the prey so that the eyes were directed towards the successful hunter and his company (Hinz, 2003).

Among the Uukwambi (Owambo/Ovambo Group) of Namibia, it was taboo to kill female animals and no more than two animals could be killed per hunting group foray (Hinz, 2003).

Among the Mayeyi of Namibia, a boy could not go hunting or fishing without first informing his father, who in turn wished him luck by praying to the ancestors saying, ‘may the grass of the fields stay away from you,’ that is may the lions of the field not harm you. When an animal was killed, the head was brought to the father as symbol of respect and appreciation for the prayers that allowed him to kill. Failure to abide by these rules could result in a failure to kill, injury to the hunter and a loss of credibility in the community (Hinz, 2003).

Among the Baka Pygmies of Southeastern Cameroon and northwestern Congo Brazzaville along the Sangha River, the consumption of bongo (a large forest antelope) was/is taboo until undergoing certain rites. The hunter of the bongo is forbidden to eat it. He and his family must undergo special rites after killing the bongo or they can fall sick and die. Children from the same village as the hunter must also follow certain rites before they can safely consume the bongo or admire its skin. A pregnant woman can never eat bongo or her child will risk suffering from epilepsy or tetanus (Nkombe, 2004). Some areas believe that eating bongo causes leprosy. To demonstrate respect to the forest spirit/god, *Djengi* or *Jengui*, traditionally it is taboo for Baka Pygmies to hunt for more meat than they and their families can consume. They can also use meat to barter for basic needs (e.g., salt, tobacco, soap, etc.), but not in excess (Biko'o, *pers. comm.*; Nkombe, 2003). Hakimzumwami (2000) describes the respect of the Baka for *Djengi* and their fear of not being able to call *Djengi* if there is no bushmeat to sacrifice. If this taboo is broken, the hunting god/spirit “*Kosé*” will punish one by, for example having one killed by an animal while hunting and/or causing one’s death by a falling branch, or turning one into a *Mboa-Mboa* (evil spirit) which roams the forest (Nkombe, 2003). Other taboos among the Baka include (Nkombe, 2003; 2004):

- The hunter cannot bathe before the hunt, especially with soap (common sense as the perfume aromas from soap can be smelled from great distances by animals and, as any soldier knows, in war time by the opposing forces). He must retain his natural odor to which the animals and forest spirits are accustomed;
- It is forbidden to have sexual relations 24 hours before small game hunting (*la petite chasse*) and 4 days before dangerous game hunting in order to avoid becoming weakened physically, morally and spiritually or losing concentration;

- It is forbidden to have sexual relations during the preparation of poisoned arrows for the crossbows (*arbaletes*). Poison is primarily hétéroside and comes from the plant *Strophantus (Strophanthus) sarmentosus*.
- It is forbidden to hunt if one's wife is pregnant;
- It is forbidden to depart on a hunt for at least 2 days after a death in the band;
- The night before departure, the hunter must participate in all rites necessary for a successful hunt and safety during the hunt;
- It is forbidden to hunt dangerous game alone;
- The one who kills a big animal and his family do not consume it;
- A young hunter who is finally able to accompany the men in the forest must give his first horned viper to the elders of the band as a gift;
- If pregnant women eat the water chevrotain, this can result in their children suffering from whooping cough;
- The Yen clan cannot eat a fish called *Nyembé* without risk of death;
- The Yékéma clan cannot eat the monkeys: *Mongenjo (Hocheur*, or greater white-nosed monkey, *Cercopithecus nictitans*), the *Mambé* (DeBrazza's monkey - *Cercopithecus neglectus*) or the *Mongenjo/ Mongaidjo (Moustac* - mustached monkey, *Cercopithecus cephush*) without risk of death;
- The Yé Ndonga clan can not eat the *Seko/Ceko* (chimpanzee, *Pan troglodytes*) as it will make one become thin and consequently cause one's death. In addition, the *Seko/Ceko* protects the clan from all dangers and diseases. Could this be related to HIV/AIDS indicating that this disease has been around for a long time and recognized by certain groups as being associated with chimpanzees (see Chapter 5, Section 5.8.1, Linking HIV/AIDS To The Bushmeat Trade);
- The Yé Ndonga clan can eat neither boa nor cobra;
- Some clans cannot eat the *Bobo/Ebobo* (gorilla - *Gorilla gorilla*);
- It is forbidden to eat wild pig as this causes bad teeth;

- Eating turtles causes hemorrhoids;
- Eating the pangolin causes skin diseases; and
- During the period of circumcision, it is forbidden for young boys to consume gorilla.

Breaking these taboos could mean death and becoming an evil spirit, *Mboa-Mboa*, by a Baka Pygmy.

Among the Baka, the *Nganga* (witch doctor, spirit medium) possesses the “Holy Spirit” or “Fire Spirit” that can indicate where the animals that will be killed are in the forest. The hunters dance the *ébalé* while the *Nganga* kneels before the fire and predicts if the hunt will be successful or not. Once the *Nganga* “sees” the animal that will be killed, he performs the *Elambé* rite, which keeps the animal in that part of the forest where it has been discovered. It is at this point that women become important to this rite, as they start dancing the *yéyi*, which is believed to bring luck to the hunter and put the animals on the hunters’ path. They depose the *mosimbé* (bloody batons) of the forest spirit *Jengui* (*Djengi*) at the feet of the hunters that will guide them to the game. The women then have the hunters drink *njambu*, a potion made from honey water and leaves, which gives them courage. The hunters then cover their front and face with a potion consisting of powdered charcoal mixed in an oil, (*le molombi*), along with powdered bark of mahogany mixed with saliva. This is applied by the hunter’s wife. With her finger, she traces from the bottom of the nose to the top of the forehead to provide good luck and to make the hunter invisible. The god of invisibility is the *Mojoyi*. As noted above, it was taboo to hunt prior to carrying out these rites, aimed at directing and protecting the hunter while giving him courage. In the end, these rituals assure that the hunting god *Kosé* is pleased, will allow them success and to return unharmed. After a kill, the Baka dance to thank *Kosé* (Nkombe, 2003).

Traditionally, the *Tuma* (elephant hunter) was highly respected for his skills and the quantity of meat provided to the Baka band. In more recent times, ivory as a commercial product has also become prized providing cash to purchase the few modern items that the Baka might need in addition to alcohol and cigarettes. The Baka distinguish a number of elephant categories: 1) *Ya*: general name for an elephant, 2) new born male and female 3) male and female without tusks, 4) elephants coming into puberty that are not to be killed, 5) *Likombe*: female adult, 6) Male adult, 7) herd of elephants, 8) *Kamba or Ekoambé*: solitary elephant, 9) *Seme*: old solitary bull, 10) *Mokilakila, Mokila or Mokela*: or man transformed into elephant and 11) *Njabo*: largest “white” elephant that leads the herd – the father of all the elephants (*likpoyo*) with large feet, no toenails and enormous ivory. He is the elephant of “God” (*Komba*), a “me” (reincarnated spirit) of the great elephant hunter *Tibola* the son-in-law of *Komba*, son of *Nyabula* who called the elephants to put them on the hunters’ trail. *Komba* killed *Tibola* so his spirit *molili* could be transformed into a *njabo* and retransformed into the great forest spirit “*Jenguï*” (Nkombe, 2004).

On the other hand, the *Mokilakila* is a destructive force of sorcerers (*wa-mbu*) whose guild has no positive role to play in conservation. Initiation to become a *Mokilakila* takes about one year of living hidden in the bush, after which all initiates enter into a hut that is set on fire with those that leave unburned being true sorcerers who are capable of transformation, not only into elephant, but also *mokela* of leopard (*sua/les Hommes Leopard*), *le mokela* of elephant (*ya*), *le mokela* gorilla (*ébobo*), etc. These transformed sorcerers are said to be evil creating jealousy and negatively impacting hunting as a means of feeding one’s family and the Baka band. The *Nganga* combat the *mokela*. The *mokela* have remedies (*molombi*) to make themselves invisible, and something they swallow *ndambu na mokila* that allows them to know when hunters are about or other dangers. The *Mokilakila* has a partner, a man transformed into the “elephant’s

dog" (*bolo a ya*) whose role it is to guard the *Mokilakila* against hunters. If a hunter attacks the *Mokilakila*, the *bolo a ya* sticks the hunter with a spear, after which the elephant passes its tusks through the speared hole. If a hunter kills the *Mokilakila*, nearby will be found the body of a man, the *bolo a ya*. If a hunter kills a *Mokilakila*, an odor is released which can indicate to the hunter that this is what he has taken. A special potion poured on the excrement of the elephant will indicate if it is a *mokila*, as well if the cord of one's *samba* or *gris gris* tightens. It is for this reason that it is taboo to hunt alone (Nkombe, 2004).

In the initiation of a young *Mokilakila*, he is given the mission of killing a *tuma*, returning with the spear or gun of the hunter. The heads of this guild take the dead hunters genitals, heart and eyes and mix them into a potion, which they apply to the young *Mokilakila* to make him stronger (Nkombe, 2003).

Interestingly enough, Mariko (1981) discusses the "Leopard-Men", or *Hommes-Leopards* of Cameroon among the Bantu, a secret society that maintained law and order, prior to the coming of the white man's laws. Similarly, to the Baka, Westerners have depicted them as ritual killers, black gangsters or even sorcerers (Mariko, 1981). Among the Mpiemu, leopard were understood to be people who had marshaled the occult powers to transform themselves in order to kill other people (Giles-Vernick, 2002). Ongaro (1972 In: Mariko, 1981) met with them and heard their side of the story. They were/are warriors of *Bot ba Ngue*, creator and protector of the people. They considered themselves, within their domain, the secret police of Black Africa, who deal with those that a Western court has not or will never condemn. They were/are the armed wing of the traditional chiefs and have existed for 100s of years. They asked, "In the forest, if someone steals, tricks someone, kicks out his wife or beats his father, will the white man's law deal with such issues"? It is the *Hommes-Leopard* who avenged/avenge the abandoned woman, or a father beaten by a son. Locally, they were/are called

Bagenge, Nyangwat, Mayman, Wahokekoko and *Simba*. Their power came/comes from *Mbok*, the fetish that reconfirms the cinders of the primordial ancestors of their tribe. *Bot ba Ngue* is the head of the *Hommes-Leopards* and these men were/are his warriors. They are given this name as a totem because in the forest it is the leopard that is the most powerful. Similar to the Baka, Mariko (1981) speaks of a variety of transformations including *Hommes-Leopard*, *Hommes-Crocodile* among the cultures in Zaire and *Hommes-Simba* (lion) in Chad with a network forming an “Interpol” of traditional enforcers. A positive view of the *Hommes Leopard* appears to be primarily present among the Bassa ethnic group of Central Province, Cameroon and may reflect the perspectives of the Catholic priest Hebga (1968 *In:* Mariko, 1981), himself a Bassa. Other Bantu cultures in the area such as the Mpiemu have similar beliefs to those of the Baka, namely that those who can transform themselves are for the most part evil sorcerers, unless certain rites are forced on them to extract the evil, consequently turning them into healers (Biko'o, *pers. comm.*).¹⁸ In the early 1980s, an official court case in Cameroon was dismissed, after the one brother explained that he shot the other, who had transformed himself into a leopard, out of self-defense. The two brothers walked off arm in arm (Schneeberger, *pers. comm.*).

The Catholic priest, Hebga (1968 in Mariko, 1981) explained the “Pact of Blood”, where a man can be a blood brother to a leopard. For a Westerner there is the body and spirit. For the African there is:

- Body;
- Heart;
- Breath;

¹⁸ Similarly, around the Selous game Reserve in Tanzania, “simba-mtu”, are bad people taking on the appearance of a lion and killing people. Afterwards they change back into human form. It is useless to hunt down such lions, the only resort being the use of a powerful witchdoctor to get rid of them (Baldus, 2005 *In:* Baldus, 2005).

- Shadow; and
- *Hou* – a fifth element monopolized by the sorcerer, a mysterious and powerful force, which can be good or bad depending upon how it is used – such as being a blood brother with leopard.

A leopard is captured and a cut is made behind its ear, and with the same knife, a cut is made on the arm of the man and the two cuts are brought together and the blood of the man and leopard is mixed bringing about a life-long bond between the two. The leopard is then returned to the forest. If one is killed, the other will die. If the man calls, the leopard will come running. The leopard becomes like a guardian angel. Similar relations occur with snakes and people, and vultures and people, etc. The leopard can take the place of a man to punish a criminal. Hebga (1968 In: Mariko, 1981) explained that this is not a physical but psychological transformation, in which the man goes into a trance and something leaves his body and goes into the body of the leopard and he becomes a leopard. While his “spirit” is in the body of the leopard, his human body is inert and hidden away from everyone. The phenomenon is said to exist across the Sahel, the author observing in the village of Ndofane, Siné Saloum, Senegal the ritual “*Jeu du Faux Lion*” (Game of the False Lion) that occurred at the end of each harvest season. The village joined together playing tom-toms, while women chanted as one member of the village entered into a trance, becoming an aggressive lion and chasing after the villagers. No one would explain the significance of this important annual sacred ritual; it is possibly a taboo to divulge its secrets to an outsider.

In the same area of Cameroon, among the Bulu, the following taboos of consumption exist(ed) (Solly, 2002):

- It was/is forbidden to eat Yellow-backed duiker, *Cephalophus silvicultor*;

- It was/is forbidden to eat the *wo'o* (chimpanzee, *Pan troglodytes*) because it is like a person. Once again, can this be linked to the fact that long ago locals realized that HIV/AIDS was associated with this species;
- It was/is forbidden to eat the *ojoé* (royal antelope, *Neotragus pygmaeus*) by pregnant women since it can be found shaking and foaming at the mouth and can cause epilepsy in the child;
- It is forbidden for women and to young men who have not undertaken the *sô* initiation to consume *sô* (bay or black-striped duiker, *Cephalophus dorsalis*). There had been a festival for the *sô* each year ‘until God came,’ Christianity;
- It was/is forbidden for children to eat *kulu* (tortoise);
- It was/is forbidden during pregnancy to eat *mvaé* (African palm civet, *Nandinia binotata*) making the birth painful and/or causing weakness and dwarfism in infants;
- It was/is forbidden for women and children to eat *ezona* (bongo, *Tragelaphus euryceros*), giving them a skin disease;
- It was/is forbidden to pregnant women to eat *nyok* (tree dassie, *Dendrohyrax arboreus*), since consumption can result in a child born with three fingers; and
- It was/is forbidden to eat *ze* (panther), *akpwe* (Gaboon viper, *Bitis gabonica*) and *ngoé afan* (bush pig, *Potamochoerus porcus*), but no particular reasons were given.

There are about 208 ethnic groups in Cameroon, the majority being of Bantu origin. Many of these groups will have the same basic taboos, with variations from group to group. Among the Mpiemu ethnic group of the Sangha Basin that includes Southeastern Cameroon (Giles-Vernick, 2002):

- Women did not venture into the forest to trap game;

- New wives were never supposed to eat bushmeat or they would earn the reputation of being a thief;
- Pregnant women were not to consume meat from their husbands', in-laws', siblings' or fathers' traps (vegetative snares, pit traps, etc.), or the traps would capture no more game, and similarly, if they were to consume fish from their nets, these would then remain empty;
- Early Twentieth century women could never prepare or eat gorilla (*ntchilo*), because gorilla found women to be sexually attractive and would threaten them in the forest;
- Women could not eat *mpa* (possibly golden cat, *Profelis aurata*). Pregnant women eating *mpa* risked giving birth to girls without vaginas;
- Women could not eat *wago* (chimpanzee, *Pan troglodytes*) because this cause them to have children with nasty dispositions; and
- Women could not eat *koi* (leopard, *Panthera pardus*), which was considered evil and killed on sight.

Nkombe (*pers. comm.*) disagrees explaining that the taboo for the golden cat was over concern for a woman giving birth to hermaphrodites. According to Biko'o and Nkombe (*pers. comm.*), both Mpiemu, the above statements concerning both gorilla and chimpanzees are incorrect. Traditionally only men and pregnant women were allowed to eat gorilla and chimpanzee. The pregnant women could only eat the forearm of these primates in order to have a strong baby that walked early. Any woman breaking this taboo risked dying in trying to demonstrate she was equal to men.

Mariko (1981) states that taboos among many of the West African cultures contain hunting ethics, the protection of certain species, as well as social mores, for example 1) no hunting when one's wife is pregnant, 2) no hunting during wife's monthly period, 3) no adultery by one's wife while hunting, 4) not allowed

to have children until stop hunting at the age of 50, 5) no killing of pregnant female, 6) the roan, *Hippotragus equines* or “horse antelope”/(*antilope cheval*) is protected as the mount of the genies, and 7) warthog are protected by Moslem hunters. Taboos of apprentice Hunters included (Mariko, 1981): 1) never shooting until the “master hunter” tells him to do so, 2) never tricking another hunter, and 3) no sexual relations with the wife, daughter, sister or friend of another hunter (Mariko, 1981). Signs of breaking a taboo included: 1) if when hunting, a hunter finds a male animal mounting a female, he knows that his wife is cheating on him, and 2) if an elephant or other dangerous game charges a hunter, this indicates betrayal by his wife (Mariko, 1981).

Among the Bakongo, to preserve the nimrodian blood in his veins, the man who kills a beast must eat its heart, sharing it only with his wife. For the same reason, they also eat the head and the neck. The wife must eat the part where the tail joins the small of the back to assure her husband’s hunting prowess. A hunter must always carry a bag of salt, to give the genies if he encounters them, so as not to be imprisoned by them. There must be no adultery by a man with a gun, or his wife. If a man habitually misses his quarry, he is guilty. If a hunter suspects his wife, he should perform specific rituals, and if afterwards he manages to kill the prey with his first shot this indicates that the wife is innocent, while consistently missing indicates otherwise (Claridge, 1922).

Similarly, Marks (1976) notes among the Bisa that concern over the welfare of a hunter also forced social mores and taboos on non-hunting family members and relatives in the villages. The behavior of their prey told them if their family in the village was remaining within expected norms. Elephants copulating indicated adultery and elephants lying down indicated mourning in the village. “The elephant never lies”, was their belief and any unusual behavior of the elephant observed by the hunters could result in an aborted hunt and a return to their camps

or villages for divination (insight) into the cause (Marks, 1976). This would most likely be accomplished through some kind of contact or sign from the ancestors or spirits. Hunting would resume once the cause of the behavior was understood and resolved.

Among the G/wi Bushmen in Botswana, animals are *kx'oxudzi* (things to be eaten), *N!Adima's* (God's) creatures that may only be killed in defense or for food. Older animals were/are to be hunted while pregnant females and even males during the breeding season were/are not hunted (Madzwamuse & Fabricius, 2004, *In:* Fabricius, *et al.*, 2004). Among the !Kung Bushmen of the Kalahari, only unfertile ostrich eggs were/are selected from a clutch, the ones with chicks being left to hatch (Wannenburgh, Johnson & Bannister, 1979 *In:* Smith, 1992).

Thus only those were allowed to hunt who had gone through a hunting apprenticeship lasting three to six years and/or had been raised in a hunter gatherer culture (e.g., Bushmen, Pygmies), and thus knew the secret rituals needed to overcome evil forces. It was taboo and a death sentence was the fate of any “unqualified” individual, possibly his family and maybe even his lineage, if he hunted. Thus, such taboos limited access to wildlife to only those individuals who had apprenticed and to whom the elders had passed on the “secrets” of how to survive the hunt.

2.1.9 Role of Women in Controlling Access to Wildlife

As noted with the Baka Pygmies, in the forest areas of Cameroon, the majority of hunting rites are controlled by women, the symbols of fertility who transmit these attributes to the forest to assure successful hunting (Nkombe, 2004). Among the Mpiemu (Mpiemu) of the Sangha Basin that includes portions of Cameroon, Central African Republic and Congo and overlaps with the Baka, women made

critical contributions to the capture, preparation and consumption of game. Women performed a secret dance when fish or meat was scarce. A pregnant woman chewed on dried maize kernels (*shogo*), spitting the maize and saliva on her husband's left hand and forehead (*Mpombi*, the bodily site of fortune) in order to safeguard the productivity of his hunting and farming activities. To moderate the anger of the *abumi* (fetus), a pregnant woman could tie a cord (*purokando*) around her husband's wrist to ensure a successful hunt (Giles-Vernick, 2002). According to Biko'o and Nkombe (*pers. comm.*), *abumi* refers to a women being pregnant, and *Mbodô* means fetus. In addition, the ritual of mixing maize and saliva on the husband's forehead is not just for hunting and farming, but also for fishing and, in general, good luck. Men can also undertake this ritual on other men for good luck. According to Biko'o and Nkombe (*pers. comm.*), the only hunting ritual undertaken by women with child among the Mpiemu is when hunting large game with nets (*la chasse au filet*). This woman with her baby (after born) would accompany the hunters to a site in the forest where the hunt was to commence. They would form a circle of medicinal herbs with the woman and child in the center. They would then pray to *Mekere*. The hunters would then disperse for their hunt, while the woman and child would be required to remain in the center of the circle until the hunters returned. This form of hunting and ritual ended about 30 years ago.

The founding ancestor of the Chiota chieftancy, Zimbabwe, is reputed to have been a hunter who brought with him his virgin sister Nyemba, who was capable of performing magic. Her magic restricted the roving elephants, permitting hunters to come upon and hamstring them (Posselt, 1924 *In:* Ranger, 2003 *In:* Beinart & McGregor, 2003). Anemasvu was believed to be the niece of the male spirit Chingowo, when the forebears of Chief Nyachuru arrived in the Concession District of Zimbabwe. When she died and was buried, her spirit entered wild

dogs and they became like domestic dogs, chasing buck into the houses of her people (Ranger, 2003 *In: Beinart & McGregor, 2003*).

2.1.10 Sport and Commercial Hunting

While the majority of game was harvested for meat, game also served a multitude of purposes, including sport and commercial uses. Human populations were low relative to the game and the weapons relatively primitive [e.g., poisoned bows and arrows, crossbows (*arbaletes*) (Figure 2.3), game pits, dead falls, and much later blackpowder muskets] so that the above traditional controls, with few exceptions, were more than adequate to assure sustainability.

2.1.10.1 Hunting for sport

Sport hunting appears to have been popular for recreational purposes, as a sign of bravery and as proof of manhood. Being under the control of chiefs and elders, its harvests were believed to be sustainable. Examples from across the continent include:

Wata “Elephant People”, Kenya

Lions and leopards were hunted to demonstrate bravery (Parker & Amin, 1983).

Maasai

Among the Maasai (Mbarnoti, 2003), the hunting of a lion usually takes place after it has killed a cow and/or as a demonstration of bravery. Hunting tends to take place in a group that encircles the lion. Generally, only *morani* (warrior age class males) hunted lion. *Morani* form an age class of 18-35 years, marking the

beginning of adulthood after circumcision; both men and women are circumcised. Men at this age raid cattle, herd cattle, protect society against invading tribes and marry. The first *morani* to draw blood with his spear is considered to “have killed the lion”. His trophy of the hunt is the tail. The second person to draw blood gets the front paw as his trophy. The lion is not eaten and the pelt is not tanned. This is considered by the Maasai as a form of “Sport Hunting”! The *morani* find great pleasure in the chase, the danger and the demonstration of their manhood and masculinity, as do many modern day sport hunters. A successful *morani* lion hunter is favored by the women much as a rugby or football star in the Western culture and this can lead to one being appointed by the committee of elders as an age group leader (*Alaigwanani*).

Zulu, KwaZulu-Natal

The classical work by Ritter (1955) talks of Shaka, the Zulu chief as a herd boy of 16 in 1803 acquiring “several light hunting assegais ‘*isipapa*’ ” and a small cow-hide shield. He spent much of his time throwing these spears until he could strike a tuft of grass with two throws out of three at 46 meters (50 yards), and moving objects after which he hunted rabbits and small buck. He killed his first leopard at 19 with a spear and club. By 1819, Shaka organized a royal hunt for elephant and other game between the White and Black Umfolozi Rivers. A hunt master and deputies orchestrated the hunt. Shaka considered the Bushmen-inherited *impinge* (spear) covered with poison unmanly, preferring the dangerous sport of getting close to and hamstringing the elephant with tomahawk-like axes. With a combination of hunters and soldiers (*impis*), a series of game pits and fences was used to funnel driven game past awaiting spearmen. Elephant and rhino were hamstrung, while antelope, buffalo, leopard and lion were speared. Upon two of his men saving Shaka from an elephant charge by giving their life, Shaka remarked, “ ‘They were the bravest of the brave....I can but reward their kraals

now and give a sacrifice to the spirits of the ancestors and mine' " (Ritter, 1955)

Eight years later 48 elephant were speared on a royal hunt organized by Shaka. Like the Maasai, described above, this appears to have had a certain amount of significance in proving ones manliness, which from a Eurocentric point of view we would call "sporting" (Chapter 3). Certainly, whatever one calls it, the Zulu enjoyed the pursuit of game as did people all over Africa, then and now.

The Ndebele/Zulu, Bulawayo

"In response to the destruction of wildlife by the early European adventurer hunter gatherers, some African rulers set up rudimentary management systems in an effort to save wild animals from extinction. Thus, Mzilikazi (the Zulu known for his hunting prowess) introduced a permit system for all European hunter gatherers in his kingdom. Under this system, gifts and other presents were given to the king in return for permission to hunt in his territory. The king also levied a percentage of the spoils of the hunt as payment for the permission" (Murombedzi, 2003).

Mzilikazi's successor, his son Lobengula, a great hunter in his youth, charged a gun fee and ammunition to all white hunters who were only allowed to hunt in the periphery of his territory. On the other hand, preferential treatment was given to Ndebele hunters, many of whom by the mid-1800s were hunting as much commercially (ivory) as for sport, taking more ivory than the Europeans. Lobengula forbade killing cow elephants or taking ostrich eggs and did so as a conservation measure. In 1833, he fined the famed elephant hunter Fredrick Courtney Selous, after whom Tanzania's Selous Game Reserve (SGR) is named, and others for shooting hippos against his wishes (MacKenzie, 1997).

The Tswana, Bechuanaland

Similarly, Khama, King of the Tswana controlled and loved hunting. He became so alarmed at the decline in game that he imposed hunting restrictions on the northern and western parts of his territory. Boer hunters were not permitted to enter and even “ ‘Englishmen have to obtain permission.’ ‘The hunting parties of the tribe....are regulated by the chief himself’ ” (Mackenzie, 1997). The importance of hunting to the Tswana is represented in a letter he wrote to the British after the annexation of Bechuanaland (Botswana), when he explained that the three things in the country that his people enjoyed were: 1) cultivated lands, 2) cattle stations and 3) their hunting grounds. He was concerned that the game would become extinct, but requested that as long as it was his country that his people should be allowed to hunt (Mackenzie, 1997). Even in the 21st century, citizen hunting, with legal government permits, is considered an inalienable right of all Botswanans, though as will be seen in the next chapter, “special licenses” for traditional hunters and gatherers have become a problem.

The Ila, Zambia

During the annual *chila* in pre-independent Northern Rhodesia (now Zambia), massed hunting with dogs and spears by the Ila brought down Kafue Lechwe (*Kobus leche kafuensis*) in the hundreds, which may have produced meat, but those who witnessed it also saw the evident enjoyment of its participants (Clarke, 2001). Lechwe herds were migratory and thus did not stay within designated village boundaries (*chichi*). “In order to secure what is called ‘optimal foraging’ in hunter studies, the inhabitants of each of the chiefdoms Mungaila, Nalubamba, Hamusonde and Chongo as well as the local Batwa Pygmies were called once or twice a year between April and May for a collective hunting time, lasting three days (the *chila*)” (Haller, 2004). It was restricted by the 1950s and forbidden

before the end of colonialism (Haller, 2004; Siamudaala, Muma, Munang'andu & Mulumba, 2005 *In: Osofsky, Cleaveland, Karesh, Kock, Nyhus, Starr & Yang, 2005*).

2.1.10.2 Commercial hunting

Traditionally, wildlife was also used for commercial purposes over much of Africa and traded with the outside world. Parker and Amin (1983) estimate that at the outset of white traders' contacts with Sub-Saharan Africa, about 300 tons of ivory left Africa annually. They estimated that initially a large percentage of this was "pick-up" ivory from an annual mortality rate of from 5-10% of which half of this would produce tusks, the other half being baby elephants. Thus, with low human populations, a passive management existed that resulted in some harvesting of elephants; however, a large amount was collected from natural die offs. Examples from across the continent include:

The Zulu of South Africa

Wildlife was hunted for its ivory by the Zulu and sold to 17th and 18th century Dutch settlers. It was important in the domestic economy supplying food, clothing and artifacts (Mackenzie, 1997).

The Sotho

Sotho settlements in what is now South Africa may have resulted from trade in animal products, such as skins, karosses, feathers, ivory and metals. The positioning of the settlement was linked to the availability of metal and trade routes to which they could channel their hunting products. They were highly

skilled in ivory carving and leatherwork (Wilson & Thomson, 1969 *In: Mackenzie*, 1997).

The Waliangulu of Kenya

In Kenya, in the region of today's Tsavo National Park, the Waliangulu, Liangulu or Wata as they call themselves, were a little known tribe of perhaps a few thousand people who commercially hunted elephant for ivory with up to 150 pound long bows and poisoned arrows (Holman 1967; Parker & Amin, 1983; Kassam & Bashuna, 2002). A significant percentage of their ivory was "pick-up" from the natural die off of elephant (Parker & Amin, 1983). It is thought that the Wata may belong to a very ancient hunting-stock that traded ivory with ancient Egyptian, Greek and Roman expeditions to the region (Kassam & Bashuna, 2002). Parker & Amin (1983) believe that the Wata were the most likely source of much of East African ivory dating back 1,200 years ago. The Waliangulu and their demise are discussed more in the Chapter 3, Section 3.9.1, Eco-Genocide and the Elephant People.

Zambezi Delta (now of Mozambique)

Between the 12th and 14th centuries, Swahili and Indian traders reached the delta and began exporting ivory and skins, greatly reducing the concentration of large herbivores, particularly elephant and hippo, from the region. Toward the end of the 19th century, the human delta population reached 100,000 and the ivory trade began waning due to the near extirpation of hippo and elephant from the delta (Beilfuss, Bento, Moore & Dutton, 2001).

Zanzibar, Ivory, the Slave Trade and the Great Lakes Region

With elephant populations devastated on the East African plateaus, the Arab traders began looking to the Great Lakes region, where elephant were still abundant (Chrétien, 2003). In the mid-1800s, working out of Zanzibar ruled by the Sultan of Oman, Hamed bin Mohammed, better known as “Tippu Tip” traded ivory and slaves for guns, using slaves to carry out the ivory. Both were sold (Brode, 2000). Tippu Tip took control of an area between the Lomani and Lualaba Rivers, making his headquarters in Kasongo in what is today a wildlife reserve in modern Democratic Republic of Congo (old Zaire/*Congo Belge*). As paramount chief among the Bantu cultivators and chosen governor among the Arab traders, he imposed taxes, built roads and plantations, and regulated elephant hunting (July, 1970). Ivory provided traders with a 200% profit.

In Bunyoro and Buganda (Uganda), ivory was a royal monopoly with half the tusks going to the kings. The main beneficiaries of this external commerce were the sovereigns and their aristocratic entourages. Towards the end of the 19th century, this resulted in the development of predatory politics, ivory and slaves being collected from peripheral areas of these kingdoms. The kings, Mutesa of Buganda and Kabarega of Bunyoro had their own armed elephant-hunting troops north of the Nile River and around Mount Elgon. These troops were organized into permanent infantry bodies, and with firearms became despotism’s new tool, resulting in the emergence of “Big Men” able to break traditional rules. Both Buganda and Rwanda participated in the slave trade from the 1880s into the early 20th century, slaves mainly coming from the divided populations of the Upper Nile and what is today the eastern Congo (Chrétien, 2003).

West Africa

The slave trade was by the Portuguese, from the 15th century until about 1800 when Britain outlawed slavery. Slaves were exported along with the ivory they carried out of the interior from Senegal to Angola (Parker & Amin, 1983) (see Chapter 3, Section 3.1.7.2, Cultural genocide).

2.2 TRADITIONAL FISHERIES MANAGEMENT

Fisheries were managed as a “Common Property Resource”, closely integrated into the culture and traditions of the communities. Fish provided important food and income for the people and there was an agreement among the users that fishery resources had to be managed judiciously and in a sustainable manner. Clan elders, in various capacities linked to the chief who had overall responsibilities for the community’s resources, were responsible for this management. Fishing was primarily for subsistence, but occasionally the fish would be bartered for agricultural goods.

2.2.1 Access to Fish Stocks, Chiefs, Lineages and Territories

Both floodplains and rivers were divided into sections under control of chiefs representing lineages.

The sedentary Kotoko ethnic group controlled fishing on the Logone River (Loth, 2004). Along the Logone River of Chad, a *chef de marigot*,¹⁹ closely allied to a number of families or villages, controlled/controls access to fishing on the floodplains. *Chefs de pêche* (fishing chief), had/have jurisdiction over a section of the main river channel belonging to a village (Dadnadji & van Wetten, 1993).

¹⁹ *Marigot* may be described as a distributary and/or side-channel leading on and off the floodplains from the main river channel

Along the Inland Delta of the Niger River (modern Mali), under Fulani rule of the 19th Century, resources were traditionally managed under a common property system called *Dina*. The principal Fulani manager was the *Dioro*, who was the head of the founding lineage of the clan. The founding lineages were the inalienable owners of resources. Heads of these lineages were called "sacrificers" with delimited territory. Each lineage had a "Master of the Water", who controlled access to and managed fishery resources. Resource managers carried out their function in consultation with the *council of elders* comprised of heads of other lineages making up the community (Moorehead, 1994). As noted, access to the multiple use of the diverse resources on these floodplains (farming, pasturage, fisheries, etc.) was strictly divided among ethnic groups (see Section, 2.1.4.3, Territory and resource management along the Inner Delta of Niger and Section, 2.2.3, Taboos) as well as clans.

Similarly, along the Niger River in Nigeria, fishermen "participate actively in the management and or co-management of the aquatic resources with the Local Water Chiefs called *Bulamas* or *Sarkin Ruwa*" (Læ, Williams, Malam, Morand & Mikolasek, 2003).

As regards Lake Victoria, in pre-colonial times, during the colonial period and even up to the early 1970s, the local fishermen felt the lake was theirs and sustainably managed the fishery resources. They developed rules about who should fish and when, where and what kind of fishing gear could be employed, based on their own accumulated experience. Similarly, to the floodplain ecosystems mentioned above, along Lake Victoria, Kenya, traditionally the management system in the pre-colonial and colonial period was based on territorial user rights. These rights were vested in the clan elder, whose jurisdiction was not only on land, but also covered the water near shore (Owino,

1999; Mutunga, 2002). Similar arrangements existed along rivers (Owino, 1999). The water beyond the clan area (deeper offshore waters) was considered “open access”, and anyone could fish within it, though access was limited by gear technology (Owino, 1999).

2.2.2 Management Interventions

2.2.2.1 Monitoring

Under the following system of fishery control, over-fishing of migratory and non-migratory species was prevented. Along the Logone River of Chad, the *chef de marigot* monitored fish yields and fish stocks on the floodplains, while the *chef de pêche* did the same in the main river channel. At the end of March, after a successful sample catch, the *chef de village* and the *chef de pêche* invited villagers and inhabitants from surrounding settlements to join in the collective fishing in the river (Dadnadji & van Wetten., 1993).

2.2.2.2 Habitat Manipulation

Among the //Anikhwe River Bushmen of Botswana, once the ponded areas on the floodplain were fished out and dried out, the men burned the dried vegetation in and around the pond so that at the next flood, the fish would have something to eat. In essence, they helped to recycle nutrients between the terrestrial and aquatic environments. This also provided a flush of fresh green grass for the livestock and wildlife (Ngaka, 2003).

2.2.2.3 Gear restrictions and use to control fishing pressure

Throughout history, the different communities of fishermen in the Sahel have learned to exploit the cycle of the floodplain fishery by allowing the spawning migration to go through virtually without intervention, and by concentrating their effort on the fish trying to regain the permanent waters of the riverbed. Many techniques exist for the blocking of the return channels with different devices. There is a very clear relationship between flood magnitude and duration linked to the annual yield/catch of fish, estimated at around 50-60 kg/ha/year of floodplain (GFCC, 1980; Hamerlynck, Duvail & Ould Baba, 2000).

On Lake Victoria, along the Kenya shoreline, there was a restriction on canoe ownership and fishing gear as a means of controlling fishing pressure. Only two fishermen were allowed to own and operate beach seine nets on one beach. These two people had to possess high moral values as a prerequisite for acceptance. Morality in this context meant freely giving fish to community members who did not have fishing gear (Owino, 1999). As with wildlife, fish was an important source of protein and, like hunters and game, it was shared freely with community members as part of a social network, where priority was placed on the welfare of the group as opposed to the individual. As with wildlife, access to fishery resources was traditionally restricted to limited individuals.

2.2.2.4 Fishing seasons

Along the Logone River, the *chef de marigot* closed/closes fishing in *marigots* from December until the beginning of April in order to enable the remaining fish stocks to recover so when the floods return, there would be/are enough fish remaining in the marigots to allow the next cycle of reproduction and growth to take place. Only in exceptional cases, when the marigots dried out, would

permission be given for villagers to harvest what would otherwise be a lost protein resource. The *chef de pêche* enforced/s a ban on fisheries in certain stretches of the main river from December until the end of March. By maintaining the ban in certain parts of the river until water levels started/start to rise in April, the presence of spawning fish at the beginning of the flood period was/is ensured, thus guaranteeing the annual influx of fish to the floodplains (Dadnadji & van Wetten, 1993). In Lake Victoria, clan elders enforced strict observation of closed seasons from February to May during the long rains, and from October to December, during the short rains, which they believed to be fish breeding seasons. This traditional knowledge has been proven valid by modern fishery biologists (Owino, 1999). Among the Uukwaluudhi (Owambo Group) of Namibia, permission to fish was required from the king who allowed an open season from August to September. Thereafter the season was closed during the reproductive season (Hinz, 2003). Among the Khoikhoi (Khoi) of the Western Cape in South Africa, the transhumance cycle revolved around a combination of pasture and marine resources, primarily shellfish and seals. During the winter rainfall (April to September), they would move to the coast for both pasture and seafood. By October, they moved inland to graze on the riparian pasture along the Berg River. Fear of over-grazing and restricted pasture nutrients (deficits in certain trace elements such as phosphorous, copper, molybdenum and cobalt) were a major reason for this continued mobility, with all basic needs carried on the backs of oxen (Smith, 1992).

2.2.2.5 Nursery grounds

Along the Logone River, from December to the end of March, each village built an enclosure in the river and dumped in refuse to provide food and a breeding area for non-migratory fish, while migrating fish from Lake Chad were provided with a protective habitat in which to spawn while awaiting the floods (Dadnadji &

van Wetten, 1993; Loth, 2004). In order to assure young-of-the-year recruitment and thus sustainable fish yields, fishermen at Georgetown, the Gambia, have traditionally prohibited fishing from certain areas (swamps) during times of the year when these serve as critical nursery grounds (DeGeorges, 1992b).

2.2.3 Fishing Taboos

By Taboo/law, in the Inland Delta of the Niger River, occupations were ethnically divided. Fulani cattlemen were forbidden to fish, this being the responsibility of Bozo and other fishing groups, while fishermen who wished to keep cattle were required to employ Fulani herdsmen. This created a division of labor and specialties among various groups with strong social and economic ties necessary for survival (Tré-Hardy, 1997).

Among the Tonga of the Zambezi River, it was taboo to fish sacred pools unless receiving permission from those responsible for the *malende* shrine (McGregor, 2003 *In:* Beinart & McGregor, 2003).

Among the Topnaar of Namibia, the night before fishing a man could not sleep with his wife, nor could a man eat fish while his wife was menstruating. The wife could not pay visits and walk about much “ ‘otherwise the fish would swim around too’ ” and he would catch little or nothing (Hinz, 2003). She was required to stay in the house with closed doors. While the husband was fishing, cold water could not be thrown on the fire (Hinz, 2003). Obviously, as with wildlife, while the husband was away fishing, taboos acted/act as a social control to keep the wife faithful.

Among the Mayeyi of Namibia, the first fish killed had to be left on the bank for the ancestors (Hinz, 2003).

In the Ankazomborona Fokotany, Madagascar, *Fadys* (taboos) control access to and thus pressure on the freshwater inland fisheries. Throughout the area, traditionally Tuesdays and Thursdays were days of rest in which no major activity of manual labor was to be undertaken. At the Fokotany of Ambato-Boeni, the fishermen spoke of a lake where it was taboo for anyone to fish commercially. This lake was set-aside for local communities to supply themselves with protein (Rajonson, DeGeorges & Booth, 1991).

2.2.4 Control of Fishing Access by Non-Community Members

On the Inland Delta of the Niger, visiting fishermen paid the “sacrificer” to sacrifice for them when they arrived in his area. They paid “in kind”²⁰ for permission to fish (Moorehead, 1994). Along the Kenyan shores of Lake Victoria, outsiders (immigrant fishermen) were compelled to seek permission from clan elders to set their equipment in clan waters. They had to give details of where they had come from and declare the type and number of their fishing gears. They also had to report to the clan elders before embarking on fishing activities and had to be settled within the local community. In so doing, the migrant fisherman was integrated into the culture and traditions of the local community, especially those safeguarding fishing activities. He had no alternative but to adhere to these rules and regulations (Owino, 1999). Among the Mafwe, Masubia and Mayeyi of Namibia, if a stranger wished to fish, he/she had to approach the village *indunas* (*kuta*) and apply for permission. The *indunas* assembled the community and they decided together if permission should be given. Illegal fishing could result in the fine of one head of cattle (Hinz, 2003).

²⁰ Goods or commodities as distinguished from money (e.g., a portion of caught fish).

2.3 TRADITIONAL MANAGEMENT OF LAND, AGRICULTURAL AND PASTURE

Land, like the other resources over most of Africa, belonged to the ancestors who delegated authority over access to and use of the land to the chief of the community. Land was to be managed as a “Common Property Resource” for the good of the community.

2.3.1 Land

By the 1700s, much of the Great Lakes region (present day Rwanda, Burundi, Uganda and western Tanzania) was divided into kingdoms and eventually monarchies. Territorial division within a kingdom/monarchy was subdivided into a province (chiefdom under colonialism) and locality. In Burundi, under the king were the chiefs (*batware*) and delegates (*vyariho*), who controlled access to agricultural and pastoral lands, among other resources. In Rwanda, there were three local authorities; army chiefs, pasture/cow chiefs and land chiefs. Under these three were “hill chiefs”, linked to powerful lineages and clans, who closely controlled the local populations and who either inherited their positions and/or were chosen by the local populace for their moral authority, wisdom and social skills. In Buganda, the *saza* (county) was modeled on traditional clan territories. Clan chiefs eventually became marginalized in the 18th century when the king (*kabaka*) appointed “chiefs of the county”, thereby redefining hill (clan) chiefs, who now had a stronger allegiance to the king than to their own people (Chrétien, 2003).

The Luhya of Kenya were divided into 20 clans, each claiming a given territory. Rights to land depended upon membership in a patrilineal descent group of clans

and sub-clans. Elders, who provided authority, were recognized for each clan and sub-clan (Mair, 1977).

Among the southern Bantu-speaking people, all land belonged to the chief and could not be alienated. Once a man was allocated a field, he had the right to exclusive use of it as long as he and his wife maintained it under cultivation. The produce of the field belonged to the cultivator, and, more precisely, the “house of the wife”, as she needed to give approval prior to the husband disposing of the produce. After harvest, and before the next planting season, the field temporarily became common property for communal grazing. Depending on the availability of water, as well as traditional practices, groups might be spread out over the landscape such as the Zulu, or concentrated in villages, such as the Sotho and Venda, which in turn affected the structure of the political administrative system: chief, sub-chief and headmen among the Zulu and a single chief among the Sotho and Venda (Hammond-Tooke, 1993).

Among the Bisa of the Luangwa Valley of Zambia, the chief allocated land, though people could settle anywhere there was available land and then advise the chief. Land surrounding the village belonged to the community, but cultivated fields belonged to individuals, subject to overriding rights by the community, which owned the land. Land not under cultivation remained common property, open to anyone’s use for prospective fields, collecting firewood, hunting and gathering (Marks, 1984).

Zimbabweans (Shona and Ndebele) derive their social identity from the soil of the land and are related to it as a baby to its mother. Land is sacred and a focal spiritual point of social identity. Without land, there can be no being. Land is about things other than monetary value. It is about the soul of the people. Land is inalienably theirs. Land is excluded from reciprocal exchange. One cannot own

land. It is a communal entity that is returned to the group one's death. It is a birthright that extends to ancestral rights. Boundaries are loose and fluid as opposed to rigid (Holland, 2001). The ancestors, accessed through spirit mediums, were and are considered the ultimate authority over land. Territorial spirits (*Mhondoro*) are royal ancestors of past chiefs believed to be the real owners of the land in Zimbabwe, protecting the fertility of the land and controlling rainfall. The goddess Nehanda and the god Chaminuka are the most powerful of the *Mhondoro*. Support from the *Mhondoro*, be it for agriculture or war, is secured through rituals of appeasement, the most important being *kutamba guva*, a dance on the grave, which is performed within a year of a chief's death. Here the ancestor is led symbolically back to his home out of the bush, where he has been living as an animal, *Mhondoro* means lion; it is believed that the chief's spirit makes its way into the body of a lion immediately after his death and then lives in the bush. The *Mhondoro* control vast tracts of land (Holland, 2001).

The Darfur region of western Sudan along the Chad border is a hot bed of friction between nomads and sedentary farmers since 2004. Historically, the indigenous groups and earlier settled Arab migrants each had their own *Dar* (tribal homeland or traditional management area). The major tribes voluntarily agreed to the settlement of other groups and accorded them a recognized administrative status (ICG, 2004). Disputes between nomads and farmers were resolved through negotiations between traditional leaders on both sides, compensation for lost crops and agreements on the timing and routes for the annual migration (Human Rights Watch, 2004).

In northern Ghana, land is believed to be the abode of the ancestors, considered sacred and meant to be passed on to future generations. The “earth priest” (Same as “*chef de terre*” in Francophone countries) or the chief controlled access to land and associated resources. In areas where land was limited, it could be inherited;

in patrilineal societies it went from father to son (Tonah, 2002). Similarly, while the chief allocated land, among the Hambukushu of the Okavango Delta, land could also be inherited by the eldest son (Mangurunga, 2003).

In the Ivory Coast, the land was communally managed, with the idea of this land being passed on to the next generation. Special rites, necessary to utilize the land, were passed from one generation to the next. Traditional society had a “master of the land and sacred forests” (*sakosé* among the Koulango, *tarfolo* among the Sénoufo and *amoinsokoé* among the Baoulé, etc.) to control access to these resources and who enforced observance of ancestral customs and celebration of traditional rites (Ibo, 1994). In southern Ivory Coast, societies were not hierarchical in nature, consisting of small-scale, widely dispersed chiefdoms, as tends to be the case in more forested environments.

However, in the 1890s Samouri Touré [See Chapter 1, Section 1.4.5.4, Samouri Touré, Dioula (Dyula) Mandinka], the last of West Africa’s empire builders, descended out of Guinea-Conakry to conquer and occupy what is now northern Ivory Coast. Residents fled much of the countryside seeking protection of the Sénoufo chief, Gbon Coulibaly, whose jurisdiction centered around Korhogo, a town that still exists today. Touré arranged, through indirect rule, to allow Coulibaly and existing structures of the chieftancy to continue ruling this area. This would eventually be taken over by the next invaders, the French who defeated Samouri in 1898. Land was the source of political authority. Chieftaincies were controlled by senior males of the Sénoufo founding lineages. Land chiefs (*tarfolo*) granted land for new villages within the lineage’s territory, which in turn paid tribute to the dominant lineage in kind and in labor. Some called this system semi-feudal. At the village level, sub-chiefs or headmen represented the *tarfolo*, creating a chain of command and political cohesion in a well structured hierarchy that fitted into power sharing relations with invading

conquerors such as Samouri Touré and the French. Each village had a portion of the lands farmed communally with the harvest being stored in common granaries. Distribution of grain was controlled by the local subchief to assure subsistence for the community. Male elders (chiefs, headmen and lineage heads) and married women with children had the right to some private land, which they could farm several days a week. Young men, marriage taking place at about age 35, provided communal labor with no right to private land. This system was considered a gerontocracy in which elders controlled the land, access to women (when a young man could marry) and the labor supply. With the exception of women, non-Sénoufo and descendants of slaves, all married men could reach the status of elders. Youth societies called *Poros* and village-level sacred forests played an important role in communal unity. During the last seven years of the 21 year initiation phase, *Poros* supplied youth to till the fields of the elders. On the death of the village head, they were required to reapply for permission to occupy the land from the *tarfolo*, reinforcing the authority of the chieftaincies of central villages over settler villages (Boone, 2003).

The *Dina* system of land management in the Inner Delta of the Niger River and land management along the Senegal River have already been described respectively in Section 2.1.4.3 (Territory and resource management along Inner Delta Of Niger) and Section 2.1.4.4 (Territory and resource management along the Middle Valley of the Senegal River).

“Originally, land tenure in Niger’s agropastoral area was characterized by the existence of three different types of tenure status. Up to the time of independence, landowners—composed of aristocratic and warrior families (village chief and their lineage, and canton chiefs and their lineage)—held a primary-ownership right. They could allocate land and receive tithe payment. Their control over land was attributed to the fact that they were members of the families who arrived first on the land considered. Use-right holders formed a second group. Having a secondary-ownership

right (they received land from the village and canton chiefs), they had to pay tithes. Their use right was secure and could be inherited by their children. A third group was formed by tenant farmers renting fields, who were vulnerable because the owner could reclaim his field at any time" (Ngaido, 1993 *In:* Vanderlinde, 2000 *In:* McCarthy, Swallow, Kirk & Hazell, 2000, Excerpted with permission from the International Food Policy Research Institute).

Among the Fulani *Lamido de Rey-Bouba* in the Bénoué Valley of northern Cameroon, the *Lamido* with both religious and secular powers due to his divine kinship linked to the Muslim religion, controlled/controls access to all resources. In his *faddah* (court), there is a *galdima* (controller of agricultural land) and "sarkin sanu" (controller over cattle and grazing) (Mayaka, 2002).

Among the Mpiemu of the Sangha Basin of French Equatorial Africa/*Afrique Équatoriale Francaise* (AEF), the *Nkang* (*Ngang/Nganga*) or diviner/healer controlled the distribution of farmland and meat (Giles-Vernick, 2002). According to Biko'o (*pers. comm.*), the distribution of land is controlled today at the level of the extended family/clan within a village.

As discussed, among the Ju//Hoansi Of Nyae Nyae (Eastern Bushmanland), residential and resource user rights were inherited from one's parents or gained through marital ties linked to a *N!ore* (territory). The size and shape of the *N!ore* was basically determined by the distribution of bush foods around the water, which are close enough for people in the *!kwana* (settlement) to get to and gather, before returning to the *!kwana* by nightfall. The plural of *N!ore* is *N!oresi*. Specific groups of Ju/'hoansi owned the *N!oresi* in the Nyae Nyae region (Eastern Tsumkwe District) (Marshall & Ritchie, 2003). It is these owners that outsiders would approach for permission to use resources or to move into the territory (Hitchcock, 2000a).

The necessity of having access to permanent waters (there were seven permanent and 94 semi-permanent waterholes in the *Nyae Nyae* region) was the ecological reason underlying Ju/'hoansi rules of land ownership. In dry periods and drought years, large numbers of Ju/'hoansi (many groups) had to be able to exercise their rights to live at a few permanent waterholes (Marshall & Ritchie, 2003). Rules of land ownership among the Ju//Hoansi were not based on game or "hunting territories", or the territories or migration routes of animals. Large game was hard to find, hunters being happy if they killed and brought home 20-30 large game animals in a lifetime (Marshall & Ritchie, 2003). The right of the *kxa/ho* (the larger land area under which *N!oresi* were subsumed) permitted anyone speaking Ju/'hoansi to traverse this "greater area" in search of water during droughts, while moving from one place to another to hunt, gather and drink water freely, to move freely in search of wounded game, and to gather key bush foods (Hitchcock 2003b). Ju/'hoansi did not make war over territory and resources except against outsiders (e.g., other ethnic groups such as the Herero) (Marshall & Ritchie, 2003). The Ju//Hoansi who lived in these areas, acted as custodians and managers of the resources.

The Basotho chief, Moshoeshoe, led his people onto the *Thaba Bosiu Mesa*, a defensive ground with pasture in the Drakensburg Mountains and with best-watered lowlands for agriculture below. Through his military leadership and cattle as social capital, Chief Moshoshoe forged a Basotho nation, today's Lesotho. Gradually, a land tenure system evolved under the control of local chiefs, which allowed each household to claim three plots to take advantage of microclimates and to allow for crop rotation; mainly sorghum and maize cultivated by women with hoes. Livestock grazed communally (McCann, 1999).

2.3.2 Pasture and Water

Smith (1992) provides an excellent historical overview of pastoralism in Africa. Additional discussions on traditional pastoralism into modern times are presented in Chapter 6, Section 6.1.3, Traditional Pastoralism in Sub-Saharan Africa.

In Northern Ghana, traditionally, grazing areas were open to all, an “Open Access Resource”, both indigenes and migrants, except in crop growing areas. In areas with limited grazing – pasture was limited to the local community and managed as a “Common Property Resource”. Natural water supplies were available to all comers (Tonah, 2002).

“Throughout the Sahel, the traditional migration routes followed by the herds, and the amount of time a herd of given size might spend at a particular well, were governed by rules worked out by tribal chiefs. In this way, over-grazing was avoided. The timing of the movement of animals was carefully calculated to provide feed and water with the least danger from disease and conflict with other tribal groups. The herders made probably the best possible use of the land. The settled part of the population, the farmers, had an equally capable understanding of their environment. They knew to let the land lie fallow for long periods -- up to 20 years -- before re-cropping, and they developed an extraordinary number of varieties of their main staples, millet and sorghum, each adapted to different growing seasons and situations” (Hardin, 1977) (Figure 2.4).

Often farmers arranged, during the dry season for herders to graze on crop residues in their harvested fields as a means of providing organic and nutrient inputs from manure.

“Within the limits of their environment and technology, the peoples of the Sahel have, over the past centuries, demonstrated an impressive record of innovation, which is quite at variance with the common negative criticism of the African as unduly conservative.

In fact, when the Sahelian peoples have been conservative and resisted changes advocated by Western experts, it has often been with reason" (Hardin, 1977).

Along the Inner Delta of the Niger River (Mali), agricultural land, pasture rights and fisheries in floodplains and fields of drylands were allocated as "common property" ("*res communes*"). The hereditary position of the "master of the land" (*chef de terre*) was responsible for management and allocation of terrestrial resources. He reported to the council of elders. Migration to and from the Delta between dry (to) and wet (from) seasons was one of the key management strategies (mobility) adopted by the rural communities to use different resources at different seasons and also to cope with climatic risk (Moorehead, 1994). Corridors between wet (interior away from floodplains) and dry season (floodplains) grazing areas were controlled and managed by various clans. Transhumance pastoralists moving through the area would request permission to graze their livestock, the time allotted to them depending on the size of their herds and the quality of that year's pasturage. On the falling floods in January, sorghum was/is planted along with cassava and groundnuts. Rice was/is planted with the rising floods of July/August and harvested as the floods receded/recede between December and February (Madeley, 2002). Bremaud (1955 *In:* Smith, 1992) outlines six stages in the normal annual transhumant cycle of pastoralists in the West African Sahel:

- **Phase 1:** First rains – the herds leave permanent water-holes/floodplains for temporary water sources.
- **Phase 2:** With the rainy season well underway – plenty of water and green pasturage – there is a movement towards *terres salées* (natural salt licks)²¹ or abundant pastures;

²¹ It was at these natural salt licks where transhumant orbits overlapped that related Sahelian Tuareg groups had their annual rendezvous for the purpose of social bonding from marriage to politics (Smith, 1992).

- **Phase 3:** Near the end of the rainy season there is a return from the *terres sallées*, using pastures available through temporary water sources (*mares*). The exhaustion of small surface water supplies (*mares*) occurs with the development of the dry season, while wild grain is harvested and grain is also obtained through exchange with sedentary peoples;
- **Phase 4:** Utilization of the same pasture by sinking wells takes place if sufficient rains have fallen to form an underground aquifer;
- **Phase 5:** Gradual movement towards permanent water sources takes place; and
- **Phase 6:** Concentration around permanent water sources during the dry season (e.g., floodplains).

Movements of pastoralists were cyclical rather than random. Scouting parties were even sent out by many pastoralist groups to determine where the best pasture was to be found and to determine the most opportune time to move the livestock. As discussed in Chapter 1, pastoralists were opportunistic, their dietary regime including bushmeat, fish, shellfish along the coast, wild grain and, in good rainfall, years cultivated grain. Prior to colonialism, certain war-like groups such as the Tuareg extracted grains from agriculturists in return for guaranteeing protection against other marauding nomadic groups (Smith, 1992) (see Chapter 6, Section 6.1.4.6, Impacts on pastoralism and range ecology from sedentarization and privatization policies).

In the Sahel, movement tends to be north south; north during the rainy season from June/July to September/October and then south during the dry season as the tsetse fly belt contracts. Traditionally in the Sahel and elsewhere pastoralists, in addition to herding, harvested wild grains, hunted and fished as the need and opportunity presented itself. Wild grains consumed include but were/are not limited to *Cenchrus biflorus* and *Panicum laetum* (Smith, 1992).

The Khoi of South Africa's Cape region, also known as the Khoikhoi, Khoisan and Hottentot, practiced transhumance, moving their animals constantly to avoid disease from trace element deficiencies (e.g., *lamsiekte* from seasonal phosphate deficiency in cattle, causing them to eat dried bones of carcasses and consequently dieing from botulism). They also moved seasonally, depending on the availability of pasture. For instance in the summer (dry season) when the pasture was scarce, the Khoi abandoned the Vredenberg Peninsula and moved inland towards the permanent waters of the Berg River. They had little competition from the Bantu, who provided them with their sheep and cattle, as this was a winter rainfall area and at the time, the Bantu had only summer rainfall crops. It would not be until the displacement of the Khoi by Dutch settlers in the mid-1600s, resulting in fencing, private land ownership and year round grazing that habitat degradation would become a major issue (Smith, 1992) (see Chapter 6, Section 6.1.4.2, Compression from expropriation of land for both European settlers and the creation of parks and protected areas).

Among the Maasai, pasture traditionally tended to be an “Open Access Resource” available to other Maasai clans, but not to other ethnic groups. This, along with local control over access to pasturage, water, etc. by extended families, was a way of assuring the sustainable management of their resources. Specific pasture (*alalili*) was set aside near permanent living areas for the grazing of calves and “weak” cattle. This was managed on a rotational basis (Mbarnoti, 2003). Most mobile pastoral groups established well-defined range reserves within their annual grazing area to provide a “savings bank” of forage. Most reserves were/are communal, such as drought reserves (e.g., Odell, 1982 *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000) and sacred sites (Schlee, 1987 *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000), but some were/are also private, such as the immediate surroundings of Maasai camps (Ole Kuney & Lendiy, 1994 *In:* Niamir-Fuller,

2000 *In: McCarthy, et al., 2000*). These reserves performed/perform the dual functions of reducing risk and maintaining ecosystem resilience (Niamir-Fuller, 2000 *In: McCarthy, et al., 2000*).

Among the Ndonobo hunters, an offshoot of the Maasai but considered a lower caste, they could only own non-milk producing cattle (Smith, 1992). Similarly, in Uganda, the Iru could only own barren cattle, breeding stock being reserved for the dominant Tutsi/Bahima (Mair, 1977). In some respects, this could have helped control grazing pressure, through controlling herd size, with the largest herds and the majority of pasture being reserved for the “political” elite.

The Gabbra are “a group of 35,000 pastoral people living in an area measuring 40,000 km² of north-central Kenya. Rainfall in the Gabbra area increases as the elevation changes, with average annual rainfall ranging from 150 mm in the Chalbi Desert to nearly 1,000 mm in the Marsabit and Kulal highlands” (Stiles, 1992 *In: Swallow & Kamara In: McCarthy, et al., 2000*). “The Ngisonyoka Turkana—10,000 people living in an area of about 10,000 km² in northeastern Kenya. Mean annual rainfall across the area is about 220 mm/year” (McCabe, 1990 *In: Swallow & Kamara In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

“The areas occupied by either group are not cultivated, although some of boundary of the area occupied by the Gabbra is cultivated.

The Ngisonyoka Turkana and the Gabbra defend the boundaries of their territories with military force. Drought conditions result in greater conflict as the groups residing in the area try to spread over more land, while at the same time, neighboring groups increasingly do the same. In normal years, the Ngisonyoka Turkana only use about 75% of their territory to avoid the risk of violent conflict and banditry from the neighboring Pokot and Karamojong groups. However, in drought years, they run the risks and rely quite heavily on the contested areas.

The Gabbra maintain particularly strong and centralized sociopolitical-religious institutions that support the common-

property regime. Wells belong to the clan or group that dug them and are managed by a ‘father of the well.’ Elected leaders, called *hayu*, act as judges. Their appointees, *jallabu*, serve as mediators. The Ngisonyoka Turkana have a more decentralized form of governance. Wells are owned by individual families and councils of elders resolve disputes (Swallow & Kamara *In: McCarthy, et al.*, 2000).

McCabe (1990 *In: Swallow & Kamara In: McCarthy, et al.*, 2000) and Stiles (1992 *In: Swallow & Kamara In: McCarthy, et al.*, 2000) argue that these systems continue functioning smoothly despite changes in national policies toward property rights, in environmental conditions, in technology, and in the activities of donor and international agencies. National policies on property rights that had so much impact in Maasailand have had little impact on the Turkana and Gabbra. However, technical and social changes initiated and promoted by nongovernmental organizations and development-assistance agencies have had a greater impact. The construction of modern wells has threatened the social bases of resource-management regimes. The availability of modern weaponry has escalated intergroup conflicts. Education has reduced the availability of labor, and the Christian religion has reduced the social bases of the property-rights regime. Population growth has not been a major driving force. On the contrary, out-migration and children’s going to school are reducing the labor available for herding. This is critical, since the systems of herd splitting and hand elevation of water from deep wells (Swallow & Kamara *In: McCarthy, et al.*, 2000)...results in the highest level of work recorded for any society in the world (Stiles, 1992 *In: Swallow & Kamara In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute)”.

The Borana Plateau of southern Ethiopia “occupies an area of about 95,000 km² in the southern part of the Ethiopian lowlands. The population of about 600,000 people is widely distributed across the plateau, with an estimated density of six people/km²” (Cop pock, 1994 *In: Swallow & Kamara In: McCarthy, et al.*, 2000).

"The area is semi-arid, with an average annual rainfall that fluctuates between 499 and 869 mm/year. Extensive livestock-production is the dominant land use....Grazing resources on the Borana Plateau (pasture and water) are to a large extent owned communally and administered by traditional elders who formulate rules governing resource use, enforce these rules, and ensure that sanctions and penalties are implemented. The social organization of the Borana pastoral system is generally based on the *gada* system which divides the Borana community into a number of age groups...The entire Borana plateau is divided into traditional administrative units called *maddas*. Each *madda* is constructed around a permanent water source (traditional deep well or permanent pond) that is administered by a 'father of the well.' The wells are of vital importance to Borana pastoralism, and all economic and social life revolves around the wells. There are nine groups of such wells in 35 locations around the central part of the plateau (Helland 1982 In: Swallow & Kamara In: McCarthy, et al., 2000). The 'father of a well' regulates its use, oversees its maintenance, and coordinates with *madda* elders on the implementation of rules, regulations, and sanctions regarding the water source. Each *madda* is subdivided into *ardas*, and each *arda* is further subdivided into a number of encampments, or *ollas*. Each *arda* has jurisdiction over some form of grazing area, cultivation land, and to a lesser extent, water resources. The *ollas* consist of at least ten households and are the smallest administrative units in the system. At the *madda*, *arda*, and *olla* levels, officials (usually elders) manage the affairs of their respective communities. At the *madda* level, decisions are made regarding which areas are left open as pasture (unsettled), which are open to settlements, and which can be brought under cultivation. Pastures can either be *fora*, *warra*, or calf enclosures. *Fora* grazing areas are available to bulls and nonlactating cows (dry herds), and are open to all Borana people. *Fora* areas also include transit areas around permanent water points. Permanent settlement is prohibited in *fora* areas. Such areas are regarded as fall-back areas 'for all' during periods of forage scarcity. Otherwise, there are few restrictions on the use of *fora* areas. Their management approximates open access. *Warra* areas are grazing areas for lactating cows and sick and weak animals. Those animals are returned to the encampment every day so that they can be milked and monitored. Areas within an *arda* designated as *warra* are open to members of the *arda* and to members of different *arda* under special arrangements. *Warra* areas are not fenced and exhibit somewhat fuzzy boundaries. Membership to a *warra* area is open to all *arda* members and is

usually very large. Grazing time is not restricted except during periods of forage scarcity, when herd-splitting agreements force dry herds to migrate...Calf enclosures are thorn-fenced fodder-banks for calves and, to a lesser extent, milking cows. Calf enclosures are only used in the dry season and only by members of a particular *arda* or *olla*. Calf enclosures have clearly defined boundaries demarcated by thorn fences. (Swallow & Kamara In: McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute”).

Among the Tswana of Botswana, until the 19th century, all cattle were the property of the chief, who allocated cattle at the level of the household for herding and milk. The *Modisa* (*Badisa* – plural) allocated grazing land and access to surface water and also controlled grazing pressure as a means of managing the rangelands from over-use (Cullis & Watson, 2005). Similarly, among the Tswana cattle-herding people of Southern Africa, a lineage group controlled both grazing and water rights. Non-lineage herders passing through the area had the right to water their cattle, but required permission to remain for long periods (Ward, 2002).

Among the Hambukushu of the Okavango Delta, there were no restrictions on how many beasts a person could rear. There were no boundaries between people with regards to grazing pastures. Anybody could graze their cattle anywhere. Different herds intermingled, with herd boys to sort them out. Grazing pressure was controlled at the village level as a “Common Property Resource”. A village could be made up of a number of different lineages, but of the same Hambukushu ethnic group. Owners of the herds, from a given village, in essence developed a pasture management plan, determining where and for how long they would graze their cattle in order to avoid over-grazing and degradation of the habitat. Where possible, reserve pasture remained ungrazed as insurance against a drought. In case of a drought and crop failure, this reserve pasture assured that enough cattle

would survive both as a source of food to avoid starvation and as a nucleus from which to build up the herd during good years (Mangurunga, 2003).

Among the Uukwaluudhi (Owambo Group) of Namibia, community members could let their cattle graze freely on communal grounds, but outsiders needed the permission of the king (Hinz, 2003).

2.3.3 Fallow Agriculture in Low Productive Areas

Over large areas of Africa, low-input agriculture with long fallow periods was and is practiced as a way of managing soils to maintain long-term fertility. Along the floodplains of the Logone River of Chad, ashes from burned floodplain vegetation were/are used as a fertilizer on the higher ridges where crops were/are planted. Once *taro* (coco yams) was/is harvested, a field was allowed to lay fallow for three years. The fallow fields provided/provide grazing for goats from the village and the cattle of nomadic pastoralists. In times of flood, the regenerating vegetation served/serves as a breeding area for fish. In the second and third years following the *taro* harvest, a tall herb, *Sesbania* sp.,²² emerges. Its wood-like stem served/serves as the main fuel resource in the village and was/is also important in the construction of fish traps and cages. Diking was/is used to trap water in rainfed rice fields. Higher up millet was/is cultivated (Dadnadji & van Wetten, 1993). In the Luangwa Valley of Zambia, the Bisa practiced shifting cultivation with long fallow periods (Marks, 1984):

- Ten years of cultivation took place before abandonment on alluvial soil along the river (Floodplains)

²² Also appears to be a nitrogen fixing legume increasing soil fertility (see Chapter 5, Section 5.12.1.1, Integrated nutrient management (INM), Integrated Nutrient Management (INM)/Low External Input (LEI) Agriculture in East and Southern Africa.

- Six years of cultivation took place before abandonment on mopane soils
(Rainfed)

The Upper Guinea forest of Central Ghana was protein rich in bushmeat and fish, but poor in carbohydrates. A 15 year fallow was developed so that each hectare plot would be in production for three out of every 18 years; taking 6 ha to support a family of five. For each hectare of virgin forest that was cleared, 1,250 tons of moist vegetation had to be removed. Fifteen years later, after fallow this required the removal of only 100 tons of vegetation. Expansion of the human population was believed to have taken off around 1500 AD, with the arrival of New World forest foods including cassava, coco-yam, peas and maize brought in by Portuguese ships. This sparked an agricultural carbohydrate revolution, allowing the forests to support an empire. Maize allowed two harvests and cassava could tolerate poor soils, drought and neglect. Plantain (cooking bananas) arrived from Asia at about the same time (see Chapter 1, Section, 1.1.3, Evolution of Modern Agriculture in Africa). Inter-cropping and minimum till agriculture were practiced with maize and cassava grown around mounded yams. Maize could be grown for three years followed by 15 years of fallow. Cassava and coco yams remained in the ground to suppress weed growth and protect soils. Cassava could be left in the ground for two-three years, providing food during the fallow periods. Small pioneer forest species were preserved and helped recycle nutrients. Eight species of trees and nine species of shrubs and herbs were known by farmers to have soil enhancing qualities. Under such a fallow system, Central Ghana could have supported 500,000 people or 130 people/km², a density attributed to the Ashante Empire in the early 19th century (McCann, 1999) [see Chapter 1, Section 1.4.8.1, Ashanti (Asante) Kingdom, modern day Ghana; Chapter 3, Section 3.1, COLONIAL STATE IN AFRICA; Chapter 5, Section 5.9.4.4, Population, commercial maize and forest loss in Ghana, 1908-1996; and

Chapter 12, Section 12.4.4.2, Impacts of structural adjustment on Central Ghana cash crop economies, fallow and virgin forests].

In the humid dense lowland forest areas of Southern Cameroon, fallow length in the mid 1980s was probably between five to ten years, farmers generally planting each field one to two years before letting it return to fallow. For every ha of food crops in shifting cultivation systems in Southern Cameroon there were 5-10 ha of fallow of less than ten years old (Ndoye & Kaimowitz, 1998)

In the Ivory Coast, fallow agriculture was used when a plot began to have poor yields or to be invaded by weeds. Letting land lie fallow also helped to control the invasion of certain crop pests and diseases. Fallow agriculture took space, depending on the number of years of production versus fallow, but it was not destructive (Ibo, 1994).

In and around the homes, women operated “*green manure*” gardens (*sunture or tapades*) to overcome the thin, poor, lateritic soils of the Fouta Djallon Mountains of Guinea-Conakry, which when they lost their organic cover became acidic resulting in the leaching of nutrients and heavy metal (aluminum and iron) toxicities. They were kept fertile by livestock manure and mulching. They cultivated maize, coco yams (*taro*), sweet potatoes, yams, manioc and fruit trees (e.g. mango, papaya, oranges and bananas) in these gardens. Maize was usually intercropped with root crops. The yields from the *tapades* were more important for household provisioning than food from other fields. Outside of the *tapade* in “open areas”, large fields with *fonio* (*Digitaria exilis*), rice, groundnuts (peanut, *arachide*), millet and sorghum were cultivated mainly by the men. This was undertaken under shifting cultivation, with long-fallow periods of up to 20 years (University of Michigan, 1985).

Among the Mpiemu of the Sangha Basin of French Equatorial Africa/*Afrique Équatoriale Francaise* (AEF), men cleared the fields, while women cultivated small one ha plots for two to three years, sometimes cultivating both rainy seasons (February-June and July-October). Fields were traditionally cultivated for two to three years and then fallowed for seven to eight years. Introduced maize (*mpusa*), possibly obtained from Hausa traders, was intercropped with cassava, yams, banana trees, peanuts, sesame, sweet potatoes, sugar cane, assorted edible greens and squashes. As people who were integrally linked to the forest and its resources, but who also farmed, the Mpiemu believed that they originated as offspring of forest and fallow deities (*Ntchambe Mekwombo*, the deity who created and commanded the forest and its people, and *Ntchambe*, the deity who taught people to cultivate land) (Giles-Vernick, 2002). According to Biko'o and Nkombe (*pers. comm.*), the Mpiemu have only one God, *Ntchambe* (see Section 2.1.6, Hunting Guilds as a Means of Controlling Access to Wildlife).

Long-fallow periods followed 3-4 successive years of growing maize, rice, sorghum and cassava, inter-grown with legumes (Fuggles-Couchman, 1937 *In: Kjekshus*, 1977) in the coastal areas of Tanzania. The fallow allowed the bush to return to what was called “Mashokora Thicket”. Fallow was for a minimum of 20 years. It is estimated that this form of cultivation could sustainably support a human population density of 15/km². Similar cultivation practices have been recorded for the Makonde/Makua people on the northern side of the Ruvuma River (Livingston, 1874 *In: Kjekshus*, 1977). Bornhardt (1900 *In: Kjekshus*, 1977) believed that at least 10 ha of forest (thicket) land would be destroyed for every one ha under cultivation. Permanent settlement, traditionally only occurred along “alluvial floodplains” such as the Ruvuma, where rice was cultivated (Livingstone 1874, I: 29 *In: Kjekshus*, 1977). These areas were “densely populated” compared to the compared to the neighboring hills and plateaus (Adams, 1902 *In: Kjekshus*, 1977).

2.3.4 Agriculture in High Productive Areas

2.3.4.1 Aksum of Ethiopia

Atop the Shire plateau, of what is now the Eritrea and the Tigray region of Ethiopia, the Aksum's empire (first to the fourth centuries AD, see Chapter 1, Section 1.5.2, Aksum) diverse ecological niche's based upon elevation, rainfall and soil types allowed farmer's to select and develop cereal and oil seed crops from local grasses including finger millet (*Eleusine coracana*), niger seed (*Guizotica abyssinica*) and teff (*Eragrostis tef*). They also adopted Near Eastern staple grains such as wheat, barley and sorghums from the Nile Valley and elsewhere in Africa. In all, there are 24 grains and oil seeds for which Aksum was a world center. Both long and short-maturing crops allowed farmers to take advantage of local climatic conditions. They were masters of water management, 75% of the rain falling from July-September, and developed an elaborate system of water harvesting, storing water in ponds and cisterns. Irrigation, terracing and soil drainage systems helped maximize crop yields. Theirs was also the only Sub-Saharan farming system to develop an ox plow before the 19th century, significantly increasing farm labor efficiency. This allowed for the accumulation of surplus grains, and the development of urban centers and armies, as well as expansion of frontiers to the north, south and west, resulting in greater access to ivory, slaves, incense, gold, etc. (McCann, 1999).

2.3.4.2 Traditional irrigated agriculture

Knowledge of irrigation appeared throughout the highlands of Tanzania (Kjekshus, 1977), the Great Lakes Highlands (Chrétien, 2003) and Kenya. By the beginning of the 20th century, some of these areas were already over-populated and experiencing soil degradation:

The Usambaras Mountains, Tanzania

Irrigation systems of great complexity had removed the risk of drought. The Wasambaa were described as excellent water technicians and irrigation that was several miles long was not uncommon (Warburg, 1984:134 *In: Kjekshus, 1977*). Terracing was also practiced. The cultivation circuit had been overextended by the 1890s (Kjekshus, 1977).

The Kilimanjaro and Upare Mountains, Tanzania

All male Chagga were educated in the creation of irrigation systems (Krapf, 1860 *In: Kjekshus, 1977*) linked to the long and short rainy seasons, assuring them a third cropping season and thus protecting them against the dry season and droughts (Volkens, 1897 *In: Kjekshus, 1977*). By the late 1890s, the mountains were already densely populated and most land was under cultivation with little opportunity for European settlement. The situation had the potential to result in conflict (Brehme, 1984; Widenmann, 1895 both *In: Kjekshus, 1977*). The human density of pre-colonial Chaggaland was $154/\text{km}^2$ ($400/\text{mi}^2$)²³ (Allan, 1965 *In: Kjekshus, 1977*). The Pare agriculture in these steep mountains was characterized by terracing and irrigation (Baumann, 1891 *In: Kjekshus, 1977*) with bananas as the staple crop.

²³ Compares with Rwanda in 1994 with 290 inhabitants/km², and 843 inhabitants/km² of arable land (11,250 km² or 43% of the territory) (see Chapter 5, Section 5.9.4.6, Deforestation in afromontane forests, Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Fuelwood, Spawning Political Destabilization).

The Usagaras, Tanzania

Dry season irrigation schemes existed from the southern Usagaras Mountains into the heavily populated valleys of Mwega, Rumuma and Munaga (Tiller, 1913 *In: Kjekshus*, 1977). Dams of stone and timber high in the valleys fed irrigation furrows. They grew sorghum, maize, sweet potatoes, beans, groundnuts, sesame seeds, sugar cane and less frequently rice, bananas, cassava and cucumbers. Crop production was for local consumption, but part was also sold to the caravan running between Kilosa and Iringa. Tobacco was also of commercial importance.

The Great Lakes Highlands

Observations in the last century and linguistics point to the knowledge of hydraulic systems in the mountains, including man-made watering places, river diversions, hollowed-out tree trunk pipes, irrigation on cultivated slopes, mounding in drained marshes and irrigation of banana and palm tree gardens on the plains of Lake Tanganyika. These forms of intensification favored sedentarization and the success of agriculture accounts for the high human densities experienced today (Chrétien, 2003).

2.3.4.3 Knowledge of soil fertility techniques in high productive areas

Integrated Nutrient Management (INM) was being practiced before colonialization. Cattle and green manuring was practiced, along with terracing in the mountainous areas (Chrétien, 2003).

Kikuyu Highlands, Kenya

The Kikuyu farmers of Kenya developed a system of rotating their crops and preserving the soil, while planting a number of different crops together so timed that one crop protected another (Leakey 1954, *In:* Hunter & Mannix, 1954).

Southwestern Uganda

“In Kigezi, there were relatively well-developed indigenous soil conservation practices, involving fields along the contour, brash lines, cultivation of legumes and simple terrace formation: as Carswell remarks, ‘at the time of the arrival of the British the Bakiga agricultural system was highly adapted, suited to local conditions and sustainable’, In place of the resistance to state-imposed soil conservation programs familiar elsewhere in East Africa, there was a considerable measure of agreement between the strictures of the District Agricultural Officers (DAO) and local practice” (Adams & Infield, 1998).

Carswell (2003 *In:* Beinart & McGregor, 2003) confirms this statement.

In the Usagaras, Tanzania

The peasants were familiar with the use of animal dung as fertilizer. Grain was always planted with nitrogen fixing legumes. Up to three crops were planted simultaneously in the irrigated fields (Tiller, 1913 *In:* Kjekshus, 1977).

Ukonde/Unyakyusa, Tanzania

In the southern Tanganyika Highlands, the Nyakyusa people adapted to the sharp changes in altitude and rainfall in their selection of crops, rotation, ridging, the use of nitrogen fixing legumes, and manure for household plots from stalled cattle to protect them from thievery (Thwaites, 1943 *In:* Kjekshus, 1977). The banana

culture of the Konde used green manure, ashes, mulching and animal dung as fertilizer in the banana fields and garden plots where three successive crops of maize, beans and sweet potato were harvested/year. As in Kilimanjaro, population pressures transformed the available grasslands to fields cultivated for staples and fodder. The critical population density of the region was believed to be 77 people/km² (200 people/mi.²) (Allan, 1965 *In:* Kjekshus, 1977).

Umatengo, Tanzania

The steep Matengo Highlands agriculture was characterized by anti-erosion techniques and green manuring and ridges (Pike, 1938; Stenhouse, 1944 *In:* Kjekshus, 1977). Cultivation was in permanent fields, with fertility built up by a box-pit method, which exposes the subsoil while green manure is building up the humus and deepening the layer of fertile soil. This was a labor-intensive agriculture, which young people abandoned for easier work under the German colonial system. Irrigation was common (DFB, 1898 *In:* Kjekshus, 1977). Once again, this system was developed under heavy population pressure, the chief's village alone having 5,000 people (Buss, 1902 *In:* Kjekshus, 1977). Maize, peas, tobacco and cotton were grown (Kjekshus, 1977).

Ufipa, Tanzania

This group practiced a system of mound cultivation to maintain soil fertility and lengthening the cropping period. Beans were grown on the green manure mounds in the first year to aid in fixing nitrogen. Green manure was allowed to rot a year before the mounds were broken down and spread over the fields. Cropping alternated between flat cultivation and mounds/ridges with alternating crops. In the miombo woodlands, they practiced "slash and burn" agriculture and fallow

periods. In plots next to the villages where tobacco was planted, urine from goats and sheep was used as a form of “animal manure” (Kjekshus, 1977).

2.3.5 Dispute Resolution over Natural Resources

Among the southern Bantu-speaking people, if someone’s cattle trampled a neighbor’s crops, the neighbor would report the matter to a sub-headman and a date was set for the hearing. The accused was asked to attend, along with witnesses. Courts were held on an as needed basis. The case was heard in the men’s meeting place, which was a prominent feature of the homestead of the chief or headman. The judge, with his assessors and close relatives, sat facing the male members of the ward. Courts were not separate from the decision-making bodies that assisted chiefs and headmen in running their wards and chiefdoms. There was no separation between the administration and the judiciary. The major goal was reconciliation, with the goal of the guilty admitting wrong and he who was in the right to forgive (Hammond-Tooke, 1993).

2.4 TRADITIONAL FORESTRY MANAGEMENT

Traditionally, there was little need to intensively manage Africa’s forests. Associated with fallow agriculture, secondary forests provided a source of firewood, medicine, and food.

In the Inland Delta of the Niger River, forest, browse and wild food resources were “open access” property (*res nullius*) (Moorehead, 1994).

However, over much of Africa, some controls were placed in the management and access to “sacred forests”, which had special religious significance to rural small-scale societies. These forests were managed as “Common Property Resources”.

One example is the sacred forest grove of the Malshegu community located in the northern administration Region of Ghana. This forest was the home of the fetish god who helped families and protected them from the invaders. All forms of farming and grazing in the sacred grove and the fetish lands were prohibited. Entrance into the grove and fetish lands was only permitted during biannual rituals honoring the Kpalevorgu god or on other special occasions with advance consent of the “*Kpalna*” (fetish priest) and other village leaders. During these occasions, some hunting and collecting of various species of rodents and birds took place; the catch was closely supervised and controlled by the *Kpalna* and village leaders. This temporary lifting of the hunting ban did not extend to reptiles believed to be harmless, the African python being considered the sacred symbol (or representative) of the Kpalevorgu god. It was nearly impossible for anybody to enter the grove without being detected, approached, and reported to local authorities. In the past, offenders were lynched. The buffer fetish lands around the sacred grove are encircled by a 1/4-1/2 km wide band of land on which only grazing is permitted. This buffer also serves as a fire belt to protect the sacred grove from annual dry-season bushfires (McCann, 1999).

2.5 CONCLUSIONS

In pre-colonial Africa, human populations were low relative to the resource base. Wildlife, forestry, fishery, pasture and agricultural lands were extensively managed. Due to the high ratio of resources to people, it was unnecessary to practice intensive management. Most resources tended to be linked to a territory owned by the ancestors, access to which was ultimately in the hands of the king/chief and his headmen who were elders within the community. Most resources were managed as common property for the good of the community, although there was some commercial use. Over a large part of Africa, hunting was considered a profession, requiring innate skills and acceptance by elders into

a guild where a three to six year apprenticeship was undertaken. The apprentice would spend most of his life under a “master hunter” until he became a “master”, who provided him with direction, and taught him in the secrets of the hunt linked to the ancestors and spirit world. Without such knowledge, one’s life and that of one’s family would be in great danger. Thus limited access to these guilds helped control hunting pressures, assuring sustainable use of wildlife for the greater good of the community. In most cases, individuals within the lineages were given responsibility for the management of aquatic (fisheries – *chef de marigot/chef de pêche*) and terrestrial (agricultural lands, pasture – *chef de terre/chef de chasse*) resources for the good of the community. Non-lineage migrants had to request permission within a given lineage’s territory to access its resources. Inter-cropping, manuring and fallow were used to maintain agricultural production. In many high yielding areas where irrigation was practiced, over-population was experienced, even in pre-colonial times.

Chapter 3

3.0 COLONIALISM AND THE IMPOSITION OF WESTERN WILDLIFE MANAGEMENT SYSTEMS

“Two aspects to consider: Civilize the people and colonize the land. Civilize the people? I would very much like to. But what an enterprise! To meld France to Africa is not only to bring together and mix two peoples...it is to bring together centuries. On the one hand, we of the 19th century, with a free press and full civilization, and on the other, the pastoral and patriarchal, the century of Homer and the Bible. Can these two peoples resemble one another, except before God? Can they mix in any way but in the tomb, when one soul resembles another, where dust resembles dust? In life they reject and exclude one another and one hunts the other. Therefore, colonize the land”, (Victor Hugo *In: Rosenblum & Williamson, 1990*).

“It is significant that pre-colonial conservation, based as it was on the unity of humanity and nature, did not create separate categories for conservation, but rather devised strategies for conserving nature while at the same time guaranteeing access to it. Although this access and use may have been mitigated by policy, religion, custom and practice to reflect existing stratification and other imbalances in pre-colonial society, the motivation for conservation was to guarantee human access to nature. This was in direct contrast with the colonial model of conservation, which has led to the development of nature conservation areas as areas cleared of all human influence and settlement (e.g., parks, game reserves and hunting blocks), with highly restricted access to resources” (Murombedzi, 2003a).

3.1 COLONIAL STATE IN AFRICA

“The barbarisms and the atrocities perpetuated by so-called Christians in every area of the world and on all the people they have been able to subjugate have no parallel in any other era of

world history, in any other race, however savage, coarse, pitiless or shameless it may have been" (Howlitt, 1838 *In:* Dumont, 1966).

"The colonization of Africa, Australia, Asia, the Arctic, the New World, and the Pacific by various European nations from the 15th to the 19th centuries saw the expansion of contacts between indigenous peoples and non-indigenous governments and agencies" (Hitchcock, 2003a).

The colonial history of Sub-Saharan Africa has many parallels with that of Latin America (Burns, 1984) and North America. Wildlife would become a point of contact between African people and European ideas. Whites would introduce both a strong market economy and firearms that tipped the scales towards over-exploitation (Carruthers, 1995). Colonialism expropriated the landscape and alienated Africans from it (Maddox, 2002 *In:* Dovers, Edgecombe & Guest, 2002). Colonialism excluded African beliefs in the intrinsic power and value of nature in favor of the Christian tenets of taming and civilizing nature (Carruthers, 1995).

"Indigenous peoples were subjected to policies that ranged from outright genocide to paternalism and benign neglect. Some groups chose to accept their situations; others resisted what they saw as an onslaught; and still others took advantage of new opportunities" (Hitchcock, 2003a).

The "division of Africa into its present countries was the product of Western interests not African minds. The lines drawn on a map by the great European powers in Berlin in 1884 still have profoundly disruptive consequences. Many traditional communities of people are now divided between two, three or even four countries. Elsewhere disparate groups, some of whom were traditional enemies, are yoked together in uneasy union, many of them lacking a common language with which to speak to one another. Colonialism favored some groups over others, creating new hierarchies...many modern African states lack any natural geographic, ethnic, political or economic coherence...The new systems were more often than not designed with a colonial wish in

mind to ‘divide and rule’ local communities. This created both artificial divisions and new hierarchies within groups and sowed seeds for conflicts after the colonial leaders departed” (Commission for Africa, 2005).

3.1.1 Colonial Autocracies

The colonial state was autocratic, not democratic (Martin & O’Meara, 1995; Leistner, 2004).

3.1.2 Loss of Land to European Settlers, East and Southern Africa

The British imperial enterprise in much of East and Southern Africa, more than any other, depended on “settler” labor – English, Welsh, Scottish and Irish. Reliance on settlers resulted in wholesale territorial engrossment. As in North America, Australia and South Africa, settlement advanced by occupying all the land (Lowenthal, 1997 *In:* Griffiths & Robin, 1997). Many of the problems that exist today (2005) in Southern Africa can be linked to a minority white group expropriating land from the majority, while compressing them into marginal, less productive areas. This will be discussed further in Chapter 5.

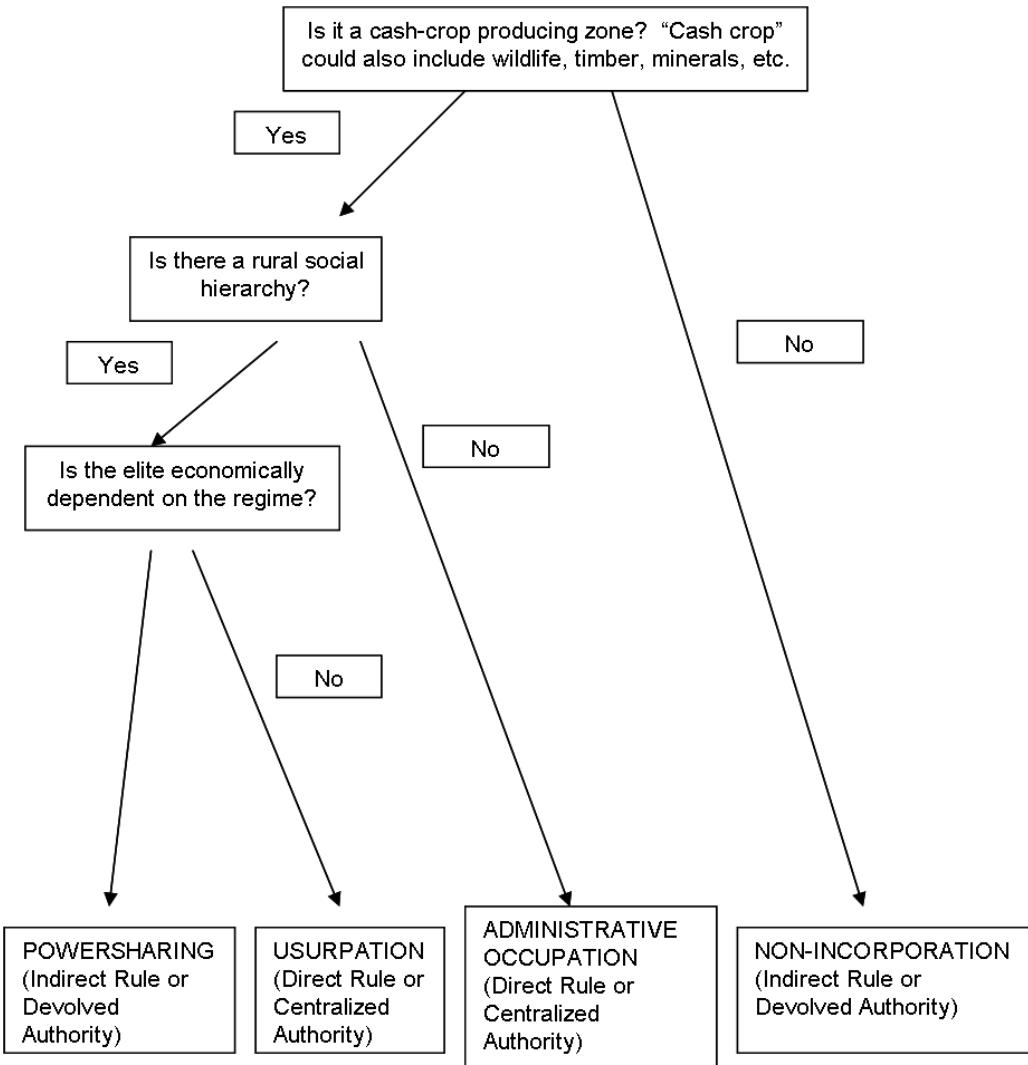

3.1.3 Creation of a Westernized Urban Elite

Very often, political and civil rights were accorded to an elite group of Westernized Africans, often of mixed-European/African blood such as the *métis* in Senegal (July, 1970; Martin & O’Meara, 1995) or *mesticos* in Portuguese Africa. The small minority of educated Africans was seen as fitting into low-level bureaucratic functions within the colonial administration that was run and operated by Europeans (Martin & O’Meara, 1995). René Dumont (1966) equates the creation by colonial powers of this “tiny administrative African elite” and

their secluded privileged existence isolated from the mass of poverty stricken peasants as a form of *Apartheid*. As will be seen throughout this document, this relationship of a minority political elite continues into the 21st century, often bolstered by government to government foreign aid (see Chapter 11) that has little or nothing to do with economic development, if anything impeding its evolution through creating welfare states and mentalities.

3.1.4 Relationships between the Rural Elite and Colonial/Post-Colonial Administrations

Boone (2003) demonstrates the relationship between the rural elite and both colonial- and post-colonial administrations as varying between direct and indirect rule, often within the same country depending on the strength of traditional rulers and the potential wealth of the area as a tax base (Figure 3.1). “Local” or “traditional” governments may or may have not been participatory and democratic, deriving power from hereditary (e.g., kings, chiefs) or spiritual (*marabouts*) authority or land tenure relations. Leistner (2004) argues that while traditional chiefs were raised in an environment where they were responsible for and held accountable for their subjects, most of the new political elites did not emanate from the traditional ruling class and thus lacked this sense of responsibility. Ayittey (1989 *In:* Leistner, 2004) observes that some of the so-called traditional “*backward and illiterate chiefs showed a far greater sense of intellectual maturity than many of the modern and educated African heads of state*”.

Figure 3.1: Determinants of institutional arrangements between rural societies and colonial/post-colonial governments

3.1.4.1 Francophone colonial Africa

Following the French philosopher Descartes, the colonial power took the approach that “we can render ourselves the master and possessor of nature”, radiating civilization in the heart of darkness. With Saint Louis, Senegal as the

starting off point, the French established themselves along the coast and eventually the interior of West Africa, establishing massive irrigation schemes along the Niger River, clearing forests for plantation agriculture, destroying traditional production systems in favor of forced labor to produce cash crops, shooting out game for sport in favor of replacing it with livestock (Rosenblum & Williamson, 1987). This basic version of colonialization would repeat itself across the continent with the Germans, British, Belgians, Portuguese and Italians. Whoever and wherever the colonial powers ventured, European visions of landscape, nature, technologies and culture were imposed on Africa as though it had no past with the only future being one of Western civilization. North, Central and South American civilizations would suffer similar fates with the coming of the Spanish *conquistadores* and eventually French and English traders, fur trappers and settlers (see Section, 3.12 COMPARISON WITH EUROPEAN COLONIZATION OF NORTH AMERICA).

Though “direct rule” was France’s official position on how to administer the colonies, on the ground it was obliged to be pragmatic (Boone, 2003). “The French ideal of ‘assimilation’ of the colonized, which became the guiding principle for most Sahelian countries, was predominated by centralism and the submission of local leaders to the power of Paris” (Kirk, 2000 *In: McCarthy, Swallow, Kirk & Hazell, 2000*).

West Africa

In West Africa, July (1970) describes French rule as quasi-military with rigid authority imposed by the French military. France practiced the policy of *regroupement* that “first emptied this colony of its distinguishing features and then remapped it as a European space and imposed modern territoriality through the creation of permanent roads and fixed villages” (Giles-Vernick, 2002). Boone

(2003) describes similar “scorched earth” militaristic *regroupement* into “strategic villages” along roads cut through the forests, resulting in the loss of control over traditional lands in southern Ivory Coast (*Cote d’Ivoire*). Traditional social structures were destroyed. Loyal agents “chiefs”, often of another ethnic groups and sometimes from another country (e.g., Senegal) were appointed to control these villages, collect taxes, produce forced labor, etc. (Boone, 2003; Vandeweghe, 2004). This would be considered a form of direct rule through usurpation. Where these structures did not exist, they were created (Martin & O’Meara, 1995). It can also be argued that the failure to achieve true devolution in Community Based Natural Resources Management (CBNRM) in modern times is due to the continued erosion of rural authority and to the value of wildlife, resulting in the state and politically connected middlemen (both national and expatriate) usurping control and being reluctant to give up direct control over income from this resource [See Chapter 9, COMMUNITY BASED NATURAL RESOURCES MANAGEMENT, (CBNRM) PROGRAMS - THE WAY FORWARD?].

Central Africa

Similarly, during the first years of the 20th century, French colonial administrators collected taxes from Central African chiefs, primarily in the form of ivory and rubber. Chiefs were threatened with imprisonment if they failed to pay taxes or to meet worker quotas. In French Equatorial Africa/*Afrique Équatoriale Francaise* (AEF),²⁴ traditional authority was gradually replaced with *circonscription* chiefs, canton chiefs and village chiefs appointed by the colonial administration and responsible for collecting head taxes (e.g., often “in kind”²⁵ such as rubber

²⁴ French Equatorial Africa was formed in 1910 by federation of three French colonies, Gabon, Middle Congo and Ubangi-Shari-Chad, eventually becoming the independent countries of Gabon, Congo Brazzaville, the Central African Republic and Chad.

²⁵ Goods or commodities as distinguished from money.

quotas) and recruiting laborers (Giles-Vernick, 2002; Boone, 2003). It is argued that head taxes encouraged local people to over-exploit resources to meet this demand (Giles-Vernick, 2002).

By the 1930s in French Equatorial Africa/*Afrique Équatoriale Française* (AEF) and Cameroon, the thinly distributed indigenous populations were obliged to regroup along roads, making everything from tax collection to health care and education easier for the colonial powers. Traditional hunting territories were abandoned or transformed and vast areas of the forest massifs that were too far from the roads returned to their wild state. This would have had a major impact on biodiversity as the mosaic of fallow agriculture and secondary forest/habitat it created would disappear. This remained the case until the end of the 20th century with the advent of commercial logging, which is fragmenting the forests and resulting in the impoverishment of wildlife linked to commercial bushmeat hunting (Vande weghe, 2004) (see Chapter 5, Section 5.9.4, Section, Forest Losses Linked to Over-Population, Agricultural and Land Scarcity, Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks And Protected Areas and Section 11.11.7, Case Study Bongo in the Congo [Brazzaville]).

In parts of French Equatorial Africa/*Afrique Équatoriale Française* (AEF), France also created *de facto* states providing large concessions to private companies with rights to mining, timber, wild rubber, wildlife and the creation of cocoa and coffee plantations (Giles-Vernick, 2002); this can be seen as a form of usurpation. According to Vande weghe (2004), in French Equatorial Africa this amounted to 40 concessions aimed at extracting resources at the lowest costs; initially rubber and ivory using inexpensive local manpower, and eventually agricultural products and timber. The French used repressive means to recruit workers by force, often by means of sending armed soldiers to raid villages. In the case of rubber, quotas

were established, which if not met could, as in the Belgium Congo (*Congo Belge*, today's Democratic Republic of Congo/DRC), result in beatings and forced labor without pay. This encouraged over-exploitation, so as to meet quotas at all costs. Those who did meet quotas were often under-paid by company agents using rigged balances. Profits were made by concessionaries paying Africans a pittance for the resources they harvested. Worker revolts were not uncommon (Giles-Vernick, 2002). Similarly, in German *Kamerun* (Cameroon) wild rubber quotas were established as part of a head tax, peaking in 1914 at 47,345 tons valued at US\$ 100 million (11.5 million *reichsmarks*) (von Meurers, 1999).

Indirect Rule

Where there were few resources, attempts at governance through indirect rule were made to administer the French colonies. This was accomplished through a limited presence using pre-existing political structures and traditional rulers as in Mauritania, Upper Volta (Burkina Faso), Chad and Niger. Zones occupied by nomadic groups living subsistence lifestyles with little economic value, *Afrique inutile*, were often left to govern themselves. People living in isolated largely inaccessible areas such as the desert and Sahelian regions (e.g., the Tuareg of Algeria, Mauritania, Mali, Chad, Niger and Nigeria) or the great lowland tropical hardwood forests (e.g., the Gold Coast, home of the Pygmies such as Southeast Cameroon and Congo Brazzaville) managed a considerable degree of autonomy, or indirect rule through non-incorporation as described by Boone (2003). In recent times, as is seen in this and later chapters, as their land becomes important for creation of parks and protected areas and/or logging, even these groups have been imposed upon by the state apparatus, often through usurpation and administrative occupation of their lands, resulting in further marginalization.

Indirect rule was based on the theories of Irish philosopher Burke, “Never entirely nor at once depart from antiquity” (Edmund Burke *In:* Elliot, 2001; Kurtz, 2003). Preserving existing political systems through co-opted traditional leaders calcified the evolution of indigenous political systems. Burke’s gradualism made colonial management easy. Nothing was supposed to happen, while the British plundered the resources of their colonies.

Indirect rule was employed by both the French (Dumont, 1966) and the English (Musah & Fayemi, 2000) with little understanding for the existing, deep-rooted social control of the residence groups, lineages, or ethnicities with regard to resource allocation (Kirk, 1997: *In:* McCarthy, Swallow, Kirk & Peter Hazell, 2000). Catherwood (2004) describes indirect rule as a means of minimal investment in manpower and money, used by the British in the form of the British Raj in India, sultans in Malaysia, Arab kings, to tribal chiefs in Africa, giving the appearance of independence, but controlled by Britain both to extract raw resources as cheaply as possible and to provide a market for British produced goods.

“With their ‘indirect rule’ and ‘native administration,’ the British recognized bundles of autochthonous rights at an early date. They thereby strengthened the position of kings, paramount chiefs, or ‘sheiks’ in pastoral societies, which they regarded as the legitimate authority system. This indigenous enforcement system intervenes as a third party with coercive power to defend the rights of individuals and groups...” (Kirk, 1997 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

Indirect Rule in Senegal

In Senegal, the residents of urban centers “The Four Communes” of Dakar, Goreé, Rufisque and Saint Louis were treated as French citizens; they were given the same education and rights, and competed and worked together with the French

in politics on an equal and integrated basis. This was maybe the only colony in tropical Africa where this occurred (Martin & O'Meara, 1995).²⁶ According to July (1970), this assimilation occurred mostly among *métis* (mixed African/European offspring) and a few Africans. However, the African elite from “The Four Communes” were more concerned about the rights of people in these urban centers than those in the rest of Senegal where 95% of the people lived (Martin & O'Meara, 1995). As in much of Africa, what happened in the urban centers had little impact on rural people (July, 1990). Eventually, Senegal’s first President, Léopold Senghor would sweep to power by aligning himself with the powerful rural Mouride *marabouts* of the Groundnut Basin and their followers, which contained over half the country’s population. This was done at the expense of the urban minority elite; a form of indirect rule through power sharing (Boone, 2003).

In the rural areas, the French dismantled the Wolof states [see Chapter 1, Section 1.4.7, Wolof (Djolof) Empire] and chose chiefs themselves based on knowledge of French and submissiveness to the Colonial power. With this, the traditional modes of social dependency were broken down, allowing Sheikh Amadou Bamba and his followers, under the Islamic Mouride Brotherhood to move in and take control over a large part of Senegal (BCC, 2006). Boone (2003) describes a rivalry between the rural *marabout* elite of Senegal’s Groundnut Basin and the urban bureaucratic elite that along with progressive planners, developers and agricultural experts in Dakar devised the idea of *animation rurale*. This was to free the suppressed peasants from the oppressive Wolof *marabouts*. Demonstrating the political power of the rural marabout elites, attempts at

²⁶ This practice continues in the 21st century in Cameroon where high level government officials (e.g., the president and his family, key ministers and their families) have dual citizenship (Cameroonian/French) and their children are educated in France (Biko'o, *pers. comm.*). It would be interesting to know how widespread this practice co-opting the political elite, is in former French/European colonies.

*animation rurale*²⁷ ended in the political crisis of 1962 in which the prime minister, progressive economist and ally of Senghor, Mamadou Dia, was removed from office, imprisoned and his followers purged from the ruling party and government bureaucracies. Usurpation by central government was extinguished in favor of power sharing between Dakar and the *marabouts* of Senegal Groundnut Basin. Unfortunately, in the case of Senegal, the rural elite, marabouts, were/are every bit as exploitative as the colonizers and urban elites (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal).

In addition, Senghor's wife was French. Jean Collin, was a Frenchman who took Senegalese nationality and married into the Senghor family (Mortimer, 2002). He was an advisor to both Presidents Senghor and Abdou Diouf, holding key positions from 1964 to 1988 and rising as high as *Ministre d'Etat, Secrétaire Général de la Présidence* under Diouf. Collin had previously served as Minister of Finance, Minister of the Interior and Minister of State in charge of the Interior (ANON, 2006). Also, Senghor's and Diouf's director of national parks until the mid-1980s was Andre Dupuy, a tough and dedicated ex-foreign legionnaire known as *mi colonel*. In most ministries, behind the scenes there was a French advisor. Thus, indirect rule existed between independent Senegal and the *marabouts*, and between France and its former colony. This relationship between France and its former colonies was probably stronger than between other newly independent states and any of the other former colonial powers in Sub-Saharan Africa.

²⁷ In the 1980s, the U.S. Peace Corps had an *animation rurale* program that placed Peace Corps Volunteers in villages, who were then to animate the village and seek small grants for "development projects". This program may have coined the words, *animation rurale* but had nothing to do with earlier politics. The impact of the U.S. Peace Corps program on rural livelihoods, though laudable, was negligible.

Usurpation/Direct Rule, the Casamance, Senegal

The usurpation of power in the Casamance of Senegal occurred as the Jola (Diola) culture lacked a political hierarchy of elites. The system consisted of very independent and decentralized villages linked through extended families and descent groups overseen by a patriarch/elder and intermediaries of spirit shrines that controlled land, agricultural production and social life. The extended family controlled access to its rice land and each nuclear family headed by a married man had control over its own share of family land. There was no land-controlling elite. With no elites with whom they could develop allegiances and administrative patronage systems, as a means of controlling peasant production systems to generate wealth for the mother country, the colonial (France) and post-colonial powers imposed military-like direct rule. This was exacerbated by the 1979 land rush by outsiders to the Lower Casamance. This action bypassed traditional allocation systems and had partially been provoked by government structures. Violence broke out in 1981 and continues in the 21st century as the Jola (Diola) of the Casamance are revolting against centralized rule from Dakar, with a guerrilla separatist movement vying for autonomy (Boone, 2003).

3.1.4.2 Anglophone Africa

In Nigeria, the “divide and rule” guided British policy. Disparities in education and religion were reinforced. In the north, the British limited Christian missions, restricted education, and strengthened the feudal rulers. In 1939, they divided Nigeria into three regions, each dominated by an ethnic group - the Hausa-Fulani in the north, the Yoruba in the southwest, and the Igbo in the southeast. The system fostered rivalries between regions and between the dominant ethnic group and minorities within each region (Booker & Minter, 2003). These examples are typical of what happened across the Continent in the non-settler colonies.

In what was to become part of Ghana, after fighting three wars that ended in defeat for the Asante (see Chapter 1, Section 1.4.8.1, Ashanti (Asante) Kingdom, modern day Ghana) in 1901, the British recognized the Asante Confederacy of states under control of a king (*asantehene*). The British governed through the existing political units and administrative hierarchies consisting of the paramount chief and a web of subordinate authorities. The system was held together by kinship and bonds of fealty between the paramount chief, divisional or wing chiefs, and village heads. The confederacy was reintegrated and strengthened by the British, who used it to govern the cocoa producing peasantry of Southern Ghana. The British enshrined into law the chiefs' claims over land and the right to demand land tribute from subjects, and the chiefs' ability to appropriate agricultural wealth indirectly in the form of political tribute and directly in the form of rent, interest and profit from cocoa growing peasants. This form of power sharing through indirect rule accentuated an indigenous social and political hierarchy in what is today south-central Ghana (Boone, 2003)

“The use of local authorities by the British (and French) colonial administration to exercise an indirect control over land led to a weakening of traditional structures” (Berry, 1992 *In:* Vanderlinde, 2000 *In:* McCarthy, *et al.*, 2000), sometimes because of their “*reconstruction*” (Cheater, 1990 *In:* Vanderlinde, 2000 *In:* McCarthy, *et al.*, 2000) as described above. Africans began to regard chiefs as agents of the colonizer (Mair, 1977; Martin & O’Meara, 1995). Both France and Britain also used African troops to fight their wars and to put down revolts in the rest of Africa; the West African troops such as the *Tirailleurs Senegalais* (Senegalese Riflemen) and the *Soave* (French colonial army, North Africa) of Francophone Africa or the Kings African Rifles in the British system became famous as fighting forces. Tens of thousands of Africans were recruited for WWI. However, for the masses, the colonial state was a foreign institution,

which operated according to unfamiliar rules and norms (Martin & O'Meara, 1995). Proxy wars, fought with African troops on the subcontinent, continue into the 21st century and are described in Chapter 13.

3.1.4.3 Portuguese Africa

The educated elite known as *assimilados* in Portuguese Africa, the *evolués* in the Belgian Congo and the “*mission-educated*” in British West and Central Africa were not allowed to engage in electoral politics (Martin & O'Meara, 1995). This was typical of the European presence in West Africa, rarely penetrating beyond the coast (July, 1970).

Thus “the configuration of rural society had a predictable effect on state building” often determined by endogenous political realities on the ground rather than by offices in Dakar, Paris, London (Boone, 2003) and Lisbon, and the value of the resources on their lands. This process of vying for control of valuable resources between central government and rural populations/factions continued through independence, is still being played out at the beginning of the 21st century and will be observed in case studies throughout this book.

3.1.5 Post WWII Sub-Saharan Africa

Following World War II, the European colonizers began improving the educational systems beyond primary schools. Britain's African colonies saw the establishment of high schools and universities, while the French government tended to send its students from its colonies off to France for their secondary and tertiary studies (Martin & O'Meara, 1995), thereby creating black Frenchmen (Rosenblum & Williamson, 1987). In the case of the French, this helped maintain the *francophonie* culture in Africa and trained Africans who were to become

functionaires (bureaucrats) in order to continue colonization from afar. In addition, this resulted in the strong ties that France still maintains with its former colonies to this day, more so than any other colonizer on the subcontinent.

From the principal author's own experience, as late as the 1980s in most of West Africa, the independent governments were hardly understood by the masses. In many instances, the children were provided with a more relevant education in the village koranic schools than in the government sponsored schools that mainly prepared them for work in "Western urban centers" (with limited opportunities in a non-existent private sector), and in over-staffed French installed bureaucracies. Koranic schools taught children how to better manage their land and their resources; little of this was initially known to the colonizers. The koranic schools were seen by the French to be backwards and repressive. In addition to religion, morality and discipline, something that 21st century schools in the West are lacking, koranic schools served as vocational schools teaching basic farming and resource management skills and passing on traditional knowledge to the next generation. Such training has unfortunately become somewhat passé as ever-growing rural populations have resulted in many traditional farming techniques, especially fallow agriculture, becoming redundant due to land scarcity.

In Senegal, the government had an impact on major urban centers such as Saint Louis, Dakar, Kaolack, and Tambacounda. This was the government created at the end of colonialism, which the West related to, but which had little impact on the day-to-day life of the majority of people living subsistence lifestyles. The rural areas had their own systems of governance dominated by *marabouts* or elders, and unless there was a need for food aid because of a drought or locusts, most people hardly needed or even understood what central or even provincial government was all about, though as noted above, with the displacement of traditional rulers, many *marabouts/rural elites manipulated/manipulate rural*

policy to their advantage in cahoots with central governments. “For most Africans, the state continues to have little meaning, as many people continue to operate outside of the ambit of its clutches” (Mohan & Zack-Williams, 2000 *In: Zack-Williams, 2002 In: Zack Williams, Frost & Thomson, 2002*). Parallel underground economies are more important to the majority than formal markets, something that is not easily measured by the World Bank/IMF and United Nations Development Program (UNDP).

3.1.6 Failure to Understand the Complexities of African Societies

Even the French, who attempted to use traditional rule, often failed to understand the complexities of African societies. This has impacted on how rural people relate to the Western governments left behind after colonialism. The French approached the royalty of the various ethnic groups in Senegal (Toucolor/Toucouleur, Serere, Wolof, Dioula/Dyula, Mandingo, Fulani/Peul, etc.) and asked them to give them their sons to be sent off for “*Western education*”. The elders and *marabouts* feared that they would never see their sons again and thus sent the sons of slaves to the French. This is believed to have been the case across much of West/Central Africa, in those areas where slavery was practiced.

The sons of slaves were trained as petty bureaucrats or soldiers, overseen by their colonial masters. Even to this day, slavery exists in West Africa among both whites (Mauritanians) (Tran, 2007) and blacks, even though it is officially outlawed. Thus, many of the high level government bureaucrats “*fonctionnaires*” who became the political elite were the descendants of slaves and were not readily accepted by the rural community, especially the descendants of royalty. Even in the 1980s, there was a well known Senegalese politician, a descendant of slaves, who was required to remain at the edge of villages and shout out his speeches during political campaigns, since as a descendant of slaves he was not allowed to

speak openly before the community under the village tree where important meetings were normally held. Thus, an educated and urbanized bureaucratic elite or *petite bourgeoisie* evolved, which stood in conflict against a rural uneducated royalty.

The creation of such relationships made it difficult for rural people to accept the authority of the state over the management of what most rural Africans saw as natural resources confiscated from them and mismanaged by petty bureaucrats, often to the latter's benefit. In addition, many of the bureaucrats, while descendants of slaves came from urban centers where the chances for secondary and tertiary education were the highest. Meanwhile, the descendants of rural royalty were not afforded equal access to Western education. Thus the cultural and social chasm between rural and urban areas, and between governments and resource users can be linked to how the colonizers related to the conquered; inadvertently educating the sons of slaves, and in more recent times educational systems favoring urbanites over rural people. These urban educated elite were and even today are being trained in Western conservation paradigms, often in Europe and the U.S., and placed in positions of power within resource management agencies with little or no sympathy or understanding for rural people and their ties to their resources. Though things are changing, the management style left behind in most of Francophone Africa from independence in the 1960s until the early 1990s was one of conflict, including separation from resources, repression and anti-poaching. This relationship, with few exceptions, was typical across the colonized subcontinent. Very often, one of the first steps that the urban-bureaucratic descendants of slave elite undertook at independence was to further marginalize any chance of the rural royal elite to impact on the politics of these countries.

René Dumont (1966) notes that “the most distressing result, from the viewpoint of African development, is the almost total lack of educated peasant elites”. He gives as an example an anti-peasant discrimination, where 75% of Bamako’s (capital of Mali) children were in school, but only 3% of the rural areas had children in Western style schools as opposed to Koranic schools. René Dumont believes the most profound evidence that Africa has made a “*false start*” is that in virtually every African country the socio-economic gulf between the peasant masses and the urban elites is greater than between these elites and the European and North American norm.

Ultimately, while the European settlers demanded all the rights of citizens living in democratic societies, they denied these same rights to Africans. This resulted in African hostility towards colonial rule and European domination, and is believed to have fueled the foment and discontent that led to the liberation wars of the 1950s to the 1980s (Martin & O’Meara, 1995).

3.1.7 Colonial Economies

Once Africa had been carved up among the colonial powers, the main objectives of colonization were to extract raw materials, create markets for European goods, and keep government costs and commitments low (Harper College, 2002; Lowenthal, 1997 *In:* Griffiths & Robin, 1997). Everything was reduced to crass materialism, which became the bane of parasitic colonial capitalism (Mafeje, 1994 *In:* Leistner, 2004). As is seen in Chapter 11, the ruling political elites at independence quickly adopted this culture of materialism, and as with colonialism do so at the expense of the masses, more often than not in collusion with the former colonial powers.

Men in charge of colonial lands tried in vain to stem the gutting of resources for short-term benefits, “making rich parents but poor children”. Many entrepreneurial practices were harmful to soils, vegetation, wildlife and even climate out of ignorance, greed or unconcern (Lowenthal, 1997). This attitude often continues in the 21st century, where multi-nationals are mining Africa’s timber, agriculture, wildlife, oil and minerals for short-term benefits with little regard for the people or the environment (see Chapters 5, 9, 11 and 13).

Peasant crops and livestock production were all but ignored in favor of export crops such as sugar, cotton, coffee, cacao and bananas produced as cheaply (meaning cheap labor) as possible for the home market. Land management and local employment were based on plantation regimes, which when abandoned often resulted in environmental and human tragedies (Lowenthal, 1997 *In:* Griffiths & Robin, 1997).

Many countries, such as Senegal and the Gambia, had their natural systems virtually eliminated as they were turned into mono-cultural economies to serve the needs of their colonial masters back home, in this case peanuts for cooking oil. Uganda and Kenya became coffee and tea estates, while the Ivory Coast grew bananas, coffee and cocoa (even in 2003 it was still the largest exporter in the world until the start of its civil war) and Liberia served as a rubber plantation.

Europeans were often subsidized, giving them a competitive advantage over emerging African entrepreneurs (e.g., Senegal) or emerging black commercial farmers (e.g., South Africa). In Kenya, African farmers were not allowed to grow coffee and other cash crops produced by white settlers. In Ivory Coast, French planters were paid a higher price for cocoa than African producers. They also used non-indigenous middlemen such as the Lebanese in West Africa or Asians in East Africa, to stifle African competition (Martin & O’Meara, 1995).

The white settler population was primarily concerned with acquiring land for plantation agriculture in attractive climates and having access to cheap labor for the mines and urban centers. In Southern Africa (e.g., Zimbabwe, Zambia, Namibia and South Africa) and East Africa (Kenya and Tanzania), the white farmers took the best agricultural land and crowded Africans on to “native reserves” similar to the Indian reservations of North America. Limiting opportunities for Africans to sell their produce on the world market, forbidding the cultivation of certain cash crops, head taxes, and compression into unsustainable land masses forced many young men to seek salaried but low paying wages on plantations, in mines or other European enterprises (Martin & O’Meara, 1995; Harper College, 2002). This is discussed in more detail in Chapter 5.

In West Africa and the Ugandan Protectorate, where colonial policies precluded large-scale European settlement and seizure of African communal lands, indigenous farmers were encouraged to grow cash crops to supply cocoa, coffee, cotton, peanuts and palm oil to European markets. The Europeans concentrated on controlling the export-import trade. However, the main beneficiaries tended to be “chiefs” and religious leaders who used their powers to allocate communal land and labor to become wealthy (Martin & O’Meara, 1995) (see Chapter 5, Section 5.6.1.8, Impacts of colonialism on traditional agriculture in Uganda). In the Groundnut Basin of Senegal, as late as the 1980s, some of the richest people in the country were the marabout holy leaders who extracted large payments from their peasant followers (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal), drove Mercedes Benzes (these elite called *Wa-Benz* in the Swahili of East Africa) and controlled the country’s politics (see Section 3.1.4.1, Francophone colonial Africa, Indirect Rule in Senegal).

As is discussed in forthcoming chapters, this resulted in the production of foodstuffs and raw minerals for the world market, most countries becoming reliant on one or two key export commodities (Martin & O'Meara, 1995) making them extremely vulnerable to volatile global market prices, which tended to favor the Western importing countries over the African producer exporting countries. As is discussed in Chapter 5, which deals with agriculture, development of cash crop economies on fragile soils, especially those of Sub-Saharan Africa's savannas had a profound effect on long-term soil fertility, social relations, nutrition, land ownership and distribution.

The increased demand for Africans' labor and/or control over how Africans used their land tended to provoke resistance rather than increase outputs and helped contribute to the rise of anti-colonial movements (Berry, 1993 *In:* Martin & O'Meara, 1995). Following the Great Depression of 1930 through to the 1950s there was a great demand for agricultural products and raw materials from Africa. By the mid-1950s and into the 1960s things began to change. World prices for African commodities began to fall. Foreign exchange fell as the price paid for raw products decreased, which in turn limited the ability to import finished products (Martin & O'Meara, 1995) (see Chapter 12, SUBSIDIES, FREE-TRADE, STRUCTURAL ADJUSTMENT AND DEBT RELIEF IN AFRICA IMPACTS ON RESOURCE EXPLOITATION).

3.1.7.1 Colonial investment in Africa

Although the colonial powers sought to induce or coerce Africans to produce crops and minerals for European markets, their effect on African economic growth was minimal. The colonial governments sought to secure a favorable environment for colonial enterprises. In East and Southern Africa, Europeans

acquired direct control of arable land, forests and minerals, and exported mostly primary products produced by European concerns. Nearly 75% of private European capital investment in Sub-Saharan Africa went to mineral exploiting regions, the Union of South Africa, South-West Africa (Namibia), Northern (Zambia) and Southern (Zimbabwe) Rhodesia and the Belgian Congo (Frankel, 1938 *In: Martin & O'Meara, 1995*).

3.1.7.2 Cultural genocide

Trevor Manuel, South Africa's finance minister, once quoted an African proverb; "Until the lions have spoken the only history will be that of the hunters" (Commission for Africa, 2005).

"In exchange for slaves, gum, ivory, gold and other 'real' riches, Europe introduced Africa to knick-knacks and trinkets, loincloths, jewels and tobacco, gunpowder and firearms (obsolete models) and worst of all alcohol" (Dumont, 1966).

Europeans began colonizing Africa over 500 years ago. The flow of wealth is still out of Africa, leaving it impoverished and often at war with itself.

As in North, South and Central America, the history of colonialization was devastating to African populations and cultures. Invading colonizers, from Arab Slave traders to European settlers, destroyed traditional ruling and social structures. This resulted in regressive societies. Societies were pushed into evolutionary dead-ends, in which both ruling elite and subjects were turned into rural subsistence peasants on lands that could not support them.

"In virtually every area of the world where colonization took place, indigenous peoples were subjected to intensive pressures to assimilate,

to become non-indigenous and therefore, to disappear...Indigenous peoples did not disappear, but rather they have endured. The pressure of assimilation efforts, however, often fractured their identities. These identities have been fortified in recent years as indigenous peoples have re-asserted their rights to traditional homelands and challenged the assumptions and mechanisms that resulted in their dispossession. In doing so, they have extracted concessions from the still-colonizing powers (often African governments manipulated and controlled by the former colonial powers, Western governments and donors or their multi-nationals) that govern them" (Hitchcock, 2003a).

In other instances, colonialization eliminated populations from possible competition with the colonizers. The human population in the Democratic Republic of Congo (DRC), the former *Congo Belge*, was cut in half from 20 to 10 million people between 1890 and 2020, while destroying traditional ruling systems. The DRC is still recovering from this trauma (Hochschild, 1998). Vande weghe (2004) states that the treatment of Africans in French Equatorial Africa/*Afrique Équatoriale Francaise* (AEF) in the sinister quest for rubber was every bit as cruel as in Congo Belge (DRC) resulting in the "rubber war" that raged until 1928 in the French colonies. For instance, found just south of the Franceville region along the Congo-Gabon border the Tsayi ethnic group was annihilated with only three out of 135 villages surviving. In fact, although the colonial period in Central Africa hardly lasted three-quarters of a century, in about a 40 year period ending around 1920, colonialism wiped out nearly 50% of the population of Central Africa from a combination of war, destruction, epidemics and famines (Vande weghe, 2004). In Namibia, the German colonizers cut the Herero population from an estimated 80,000 landed people to fewer than 20,000 landless people between 1903 and 1906 (Hochschild, 1998). Woods (2007) provides a figure of 65,000 Herero killed by the Germans, with 45% of those remaining (not going into exile) in Southwest Africa (Namibia) dieing of "malnutrition, disease, exhaustion, exposure, neglect and brutality". Similarly, a 1901 population of 20,000 Nama was reduced by the Germans to 9,810 by 1911 (Woods, 2007).

One of the worst tragedies in modern history was the supplying of slaves to the plantations of the New World. It is estimated that approximately 50 million Africans were torn from their motherland and taken to America as unwilling instruments in laying the foundations for Western capitalism. They were uprooted from their families and cultures, and sold off as chattel to become beasts of burden, to supply cotton from the emerging American colonies, or fruits, spices, and sugar cane from the Caribbean islands, Central and South America. Unequal exchange became characteristic of international commerce with Africa always at a disadvantage. African wealth from human beings to crops and precious minerals was exchanged for worthless articles like trinkets, mirrors and beads (Museveni, 1997). Leistner (2004) estimates that 22 million people were sold into slavery between 1500 and 1890 to the Americas, Middle East and elsewhere. The actual number of slaves arriving in the New World from the West Coast of Africa ranges from 10.2 million (Lovejoy, 2000) to 11.3 million (Thomas, 1997) to 15 million (Leistner, 2004), these numbers representing from 10% (White, 1993) to 70% (Mintz, 2003) of the actual number that survived between capture and arrival in the New World. Inikor (1992 *In:* Leistner, 2004) provides two estimates for the East Coast slave trade: 10 million sold into slavery from 1400-1900, the other 6,856,000 between 1500-1890.

When the colonial penetration into the interior of Africa began in earnest in the 19th century, it was evident that the slave trade had resulted in tragic social disruption and ethnic strife. Thus, the slave trade was finally stamped out at the end of the 19th century, not entirely on a moral basis but to help create peace, stability and an orderly administration, which could then efficiently supply raw products to the Mother country (Leistner, 2004).

3.1.8 Ecology, a Science of Empire

The establishment of ecology as a formal science occurred in 1866 and is associated with German zoologist Ernst Haeckel. Ecology is a combination of two Greek words, *oikos* meaning domicile of a planet and *logos* meaning origin or root – in this case of scientific knowledge. Thus, ecology is “the scientific study of the early dwelling place” or “home”. Haeckel used ecology to imply the study of organisms and how they relate to the natural environment as opposed to the laboratory. This then distinguishes ecology from biology, which is more about the structure and function of an organism and its systematics. The first professional society, the British Ecological Society was established in 1913 (Keller & Golley, 2000).

In America, the science of ecology was born in Midwestern agricultural colleges in the late 1800s as a means of studying changes in plant communities. In 1920, the American Ecological Society’s new journal, *Ecology*, first appeared, broadening this science to animal ecology, and changing it from a “pure” to an “applied” interdisciplinary biological science (Robin, 1997 *In: Griffiths & Robin, 1997*).

Contemporary ecology relies on physics, chemistry, molecular biology and the biology of the organism to discover natural patterns and processes that describe how organisms, groups of organisms, and interactions between organisms (e.g., predator – prey relationships) interact with and relate to the physical, chemical and biological components (e.g., vegetation, soils, climate, etc.). Discussed as an entity, these interactions are defined as an ecosystem.

Ecological imperialism suggests superhuman achievements of European expansion into the colonies, which brought with it the imposition of values and

management systems based on the Linnaean classification of plants and animals, and the concept of reserves and parks (i.e., preservation), which separated humans from nature. Indigenous management systems and knowledge were ignored (Keller & Golley, 2000).

Imperial settlers were hardly aware of the manipulation of nature by indigenous peoples. They assumed that the landscape they encountered for the first time was untouched “virgin territory”, “almost fresh from the Maker’s hands”. The French called what they believed to be unoccupied and unused lands ‘*terres vacantes et sans maître*’ even though they served as important reserves in the bush fallow agricultural cycle and/or for hunting and tree crop gathering (Zeba, 1998).

That indigenes without permanent farms or advanced tools, over millennia, profoundly altered New and Old World landscapes (including Africa), and were still doing so, went unrecognized. It suited colonial incomers to overlook signs of native alteration; the apparent absence of indigenous improvements, helping to justify the removal of indigenes from tribal lands to make way for the sophisticated European settler. European settlers were ill equipped to judge the impacts of semi-nomadic hunter gatherers, migratory pastoralists and shifting cultivators on the environment, especially the cumulative impacts of fire on vegetational communities. Indigenes, unable or unwilling to abandon “*primitive*” practices for permanent settlement were doomed to give way to the superior races with advanced technologies (Kjekshus, 1977; Lowenthal, 1997 *In:* Griffiths & Robin, 1997). In July, 1895 the Frenchman Jules Ferry declared that “ ‘The Declaration of the Rights of Man was not written for the Blacks of Equatorial Africa’ ” (Dumont, 1966). General Meynier (Meynier, 1911 *In:* Dumont, 1966) wrote,

“ ‘From the first day of their encounter, Europeans affirmed the principle of their superiority over the black race...They have forced

the Africans into slavery, justifying it on the basis of superior strength...To open markets for their trade in Africa, they have stamped out the last vestiges of African civilization. If one compares their (European) methods to the Berbers and even the Arabs, the parallel to this day does not favor the Europeans' ”.

This envisaged Europeans, moving out of Europe into Africa, North America, South America, Australia and New Zealand, creating Neo-Europe, unleashing an ecological/biological imperialism of crops, weeds, germs and pests that were imperialistic because of their ability to reign supreme over competitors and establish ecological dominance (Williams, 1997 *In:* Griffiths & Robin, 1997). In many instances, the European colonizer brought in anarchy and chaos, disrupting traditional management systems, imposing Western systems of governance on other cultures, while bringing indigenous systems to an evolutionary dead end, and ultimately taking away the self-respect and dignity of a once proud people through the creation of second class “indentured servants” to European settlers, a stigma that to this day may still be holding back the continent from the envisioned “African Renaissance”.

The Scottish missionary Robert Moffat perceived environmental control as the distinctive characteristic of the Christian, contrasted with the heathen African's alleged helplessness. For Sir Charles Eliot, Commissioner of the East Africa Protectorate at the turn of the 20th century, the problem with Africa was that the environment needed to be controlled and transformed. Eliot stated that

“Nations and races derive their characteristics largely from their surroundings, but on the other hand, man reclaims, disciplines and trains nature. The surface of Europe, Asia and North America has been submitted to this influence and discipline, but it has still to be applied to large parts of South America and Africa. Marshes must be drained, forests skillfully thinned, rivers taught to run in ordered course and not to afflict the land with drought or flood at their caprice; a way must be made across deserts and jungles, war must be waged

against fevers and other diseases whose physical causes are now mostly known" (MacKenzie, 1997 *In: Griffiths & Robin, 1997*).

The blind arrogance of the European colonizer failed to realize how advanced some of these societies were, favoring the pre-conceived prejudiced opinions of the early explorers and hunters that the Continent was a land of savages who would require the Judeo-Christian value system, work ethic and technologies to advance their civilizations. They failed to realize that the African landscape had already been modified, manipulated and controlled by humans through the use of fire, livestock and even iron tool technologies.

3.1.8.1 Ecology of an empire in Tanganyika and Kenya

Prior to 1890, pre-colonial Tanganyika (Tanzania) had an advanced agricultural society and, one could argue, the beginnings of an industrialized society. As described in the previous chapter a combination of livestock, fire and hunting had been used to "push back the bush" and the associated wildlife and tsetse fly, many of today's parks and protected areas having more people and cows than game during the pre-colonial period. Man had dominion over nature.

Comfort and plenty characterized the life among the majority of the people in 19th century Tanganyika. The skilled craftsmen, or *fundi*, were considered every bit as skilled as the best European craftsmen and ranged from forgers of spears and arrowheads to makers of shields, bows and arrows, hoes and tools, to cotton and bark cloth weavers, to boat builders, specialists in making traps, fishnets and sails, to gunsmiths. The transformation of raw products gave added value to these commodities and stimulated the local and regional economy. Irrigation was highly developed in the mountainous regions. Blacksmiths were known in every tribe; the transition from wood to iron hoes occurred in the early 19th century and is believed to have taken place in areas where a transition was made from "slash-

and-burn" agriculture with a long fallow period to a more sophisticated agriculture. The development of an inorganic salt industry is correlated to the development of agriculture and a diet dominated by vegetables as opposed to meat (Kjekshus, 1977).

Until out-competed by cheaper imports from America and Asia in the 1850s, cotton was grown with cotton-weaving industries beginning in Zanzibar and spreading to Kilwa on the East Coast, along the Rovuma River west to Lake Nyasa (Malawi) and in a border corridor from Lake Nyasa to Lake Tanganyika northward to Lake Victoria Nyanza. Additional commodities included pottery, cattle, donkeys, tobacco, bananas, robusta coffee, fish, grain (maize, millet, sorghum and rice) and ivory (Kjekshus, 1977).

Women-driven trading took place within ethnic groups. Border markets existed, where an exchange of goods took place between ethnic groups. Internal trade was believed to be more important than the external trade of slaves, ivory, etc., and indicated a relatively sophisticated agricultural economy in which food surpluses were marketed. The caravan trade from the coast even resulted in a regional market of 10,000 residents at Taveta (Kenya) around Mount Kilimanjaro. While introducing new crops and stimulating agricultural production, the caravan trade was nonetheless dwarfed by the number of people involved in the local markets and indigenous commodity trade (Kjekshus, 1977).

However, by the time the Europeans arrived in East Africa in the 1890s, this life had changed, mainly due to human, livestock and wildlife diseases inadvertently introduced by the colonizers, helping to solidify the latter's prejudices concerning the backwardness of the "natives". These catastrophic events combined with misdirected colonial policies from the 1890s through the mid-1900s resulted in

rural Tanzania's loss of control over nature and the eventual spread of bush (Kjekshus, 1977; MacKenzie, 1997; Chrétien, 2003):

- Rinderpest, believed to have been introduced by Europeans, devastated wildlife and cattle throughout East and Southern Africa;
- Small pox was introduced by Europeans/outsiders;
- The sand flea was introduced by Europeans through Angola;
- Locusts were linked to drought – wet cycles;
- The Maji Maji Rebellion of 1905 against colonialism;²⁸
- Food procurement for military purposes by Europeans linked to WWI;
- Colonial warfare with the Germans in WWI presented another European intervention;
- Forced labor by the Germans/Europeans;
- Famine associated with the above;
- Eventually, European imposed wildlife reserves; and
- Eventually, villages were concentrated as part of a tsetse control imposed by Europeans.

Vande weghe (2004) places the introduction of rinderpest via Djibouti in 1880. Wildlife, as it recovered quicker than livestock from rinderpest and sleeping sickness was favored over cattle. By 1937, 66% of the country, and thus prime wildlife habitat, was occupied by tsetse fly compared to 33% in 1913 (Kjekshus, 1977).

²⁸ “The *maji* or magic water, which was reputed to prevent German bullets from killing, came from a shallow well called Kisima Mkwanga just by Kingupira in the eastern Selous. The Germans applied a scorched earth policy – burning huts, laying waste and destroying crops. The Maji Maji fighters did the same against villages which did not join them” (Rodgers, 2005 *In: Baldus, 2005*).

The combination of these events resulted in the de-development and impoverishment of rural Tanzanians. It is estimated that 750,000 people died of hunger between 1894 and 1899. Also, it is estimated that human populations in the East Africa/Great Lakes region did not return to pre-1890s levels until the 1950s (Chrétien, 2003). At a crucial stage in the retreat of man and cattle from the advancement of nature, a new ecological balance was established in which “nature” and “not man” was in control (Kjekshus, 1977; MacKenzie, 1997).

The arrival of the colonial powers at this time failed to realize the changes that had taken place, resulting in a breakdown in interaction between the two civilized societies. The colonizers saw East Africa as nothing but ‘blank, uninteresting, brutal barbarism,’ mistakenly judging the conditions of life in this period to represent the height of East African development (Eliot, 1903 *In:* Kjekshus, 1977). What had been a peaceful relationship between herders and agriculturists, in which trade was implicit and mutually beneficial, broke down, as starving pastoralists began raiding to survive (Sander, 1893 *In:* Kjekshus, 1977). Kjekshus (1977) believes that the intense tribal raiding the Germans experienced was the direct consequence of economic losses suffered initially through rinderpest. Similar events also occurred in Kenya (Dublin, 1991 *In:* McCann, 1999) and Uganda (Hulme, 1997) resulting in comparable disruptions in the society and ecology.

Spreading southward, it is estimated that around 1896 rinderpest killed 500,000 cattle in Rhodesia, 600,000 cattle in the land of Khama (Botswana) – 90% of the livestock population, 1 million cattle in the Transvaal – 67% of the livestock population (Doctari, 2005) and 60% of Southwest Africa’s (Namibia) cattle (Woods, 2007). The disease broke through the fenced Orange River barrier in March 1897. By that time, Drs. Koch and Theiler²⁹ had developed both a bile

²⁹ Founder of world-renowned Onderstepoort Veterinary Research Laboratory, South Africa.

method and a serum virus method of immunization. Quarantine, control and immunization allowed 67% of the cattle in the Cape Colony to survive. Although this disease pandemic was finally stamped out in 1898, it re-appeared in 1900 in South West Africa (Namibia) and in 1901 in Basutoland (Lesotho). It was finally eradicated from South Africa in 1905, after a total loss in South Africa alone of 2.5 million heads of cattle (Doctari, 2005).

Rinderpest was seen as a subduing force aiding the colonial takeover, by taking the fight out of the war-like Maasai (Lugard 1893 *In: Kjekshus, 1977*). Because the Maasai were totally dependent upon cattle for food, an estimated 66% of the Maasai tribe died (Baumann, 1894 *In: Kjekshus, 1977*). While Baumann found that the warriors survived through hunting and petty thieving, the majority of the Maasai lived as beggars among neighboring peasants. Lugard (1893 *In: Kjekshus, 1977*) found that 90% or more of the cattle died in Kenya and Uganda. While agricultural societies could avoid starvation with their crops, the nomadic pastoralists were starving to death. It is estimated that 95% of all cattle died in East Africa (Sharpe, 1893; Stuhlmann, 1894 both *In: Kjekshus, 1977*), resulting in one of the “twin pillars” of the traditional economy – the lifeline of the people – being torn away (Kjekshus, 1977).

Further south, the vision of the famed missionary David Livingstone was one of vast cotton fields down the banks of the Zambezi River populated by the poor of central Scotland (MacKenzie, 1997 *In: Griffiths & Robin, 1997*). Was it this same eco-imperialistic vision of man’s ability to control and manipulate his environment in the 1970s/80s, that led planners to ignore traditional production systems, resulting in the displacement of between 500,000 and 800,000 people on the Senegal River from the construction of dams and planned irrigation which ended up proving economically and ecologically unviable (see Chapter 7, Section

7.9.1, Dam Impacts on Displacement of People and Section 7.9.1.1, Senegal River)?

All of this was occurring at a time when the sciences were professionalizing and the ideology was developing of scientific colonialism that could socially engineer African societies to improve their lifestyles. Colonialism conferred tremendous power on the sciences, which became tools of the empire to solve human and administrative problems and increase human progress. Ecology was seen as a means of linking the fields of natural and social sciences. In 1929, the African Survey carried out by British ecologists, botanists, entomologists, zoologists, soil scientists and veterinarians emphasized the importance of local knowledge and the ability of Africans to sustainably manage their environment, contrary to popular belief. This included an intimate knowledge of soils and other factors that once lost by the imposition of often inappropriate colonial practices, was difficult to recover. In some cases traditional slash and burn fallow agriculture (*chitemene/jachère*) of nutrient poor soils provided better yields than imported European methods, assuming the area of land relative to the population was large enough. Africans practiced crop rotation, anti-erosion methods and fertility enhancing practices (Tilly, 2003 *In:* Beinart & McGregor, 2003) (see Chapter 2, Section 2.3, TRADITIONAL MANAGEMENT OF LAND, AGRICULTURAL AND PASTURE).

Lately, the view of indigenes' impact on nature has been turned upside down, with tribal people across the world being heralded as ecological gurus whose reverence for nature is held necessary to repair the ravages of technological greed. However, just as indigenes changed their environment more radically than settlers realized, they also wrought environmental havoc such as the extinction of the moas in New Zealand, soil exhaustion in central Mexico, salinization in the Tigris/Euphrates and wholesale ecocide among Arizona's Anazasi and

Guatemalan Mayans. To view indigenes as incapable of harm is as dehumanizing as earlier notions that they could do no good. Romantic primitivism jeopardizes the ability to rationally assess the impacts of peoples on their environment (Lowenthal, 1997 *In:* Griffiths & Robin, 1997; Diamond, 2005). Sahelian civilizations (see Chapter 1, Section 1.4, WEST AFRICAN KINGDOMS AND EMPIRES) and Mwanamutapa (Great Zimbabwe) (see 1.7.3.2, Chapter 1), among others, provide examples in the demise of Sub-Saharan African civilizations from apparent over-population and mismanagement of natural resources, ultimately a major reason for the Bantu migrations off the Adamoua Plateau of Central Africa and their continued movement east and southward to the Cape (see Chapter 1, Section 1.7, BANTU AFRICA).

3.1.8.2 Natural resources in early colonial Africa

“At the time when explorers established contact with Africa and pushed further inland and developed a lucrative trade in spices, ivory, and forest products in exchange for alcohol and various manufactured goods, the prevailing development ideology in Europe was based on the Old Testament idea expressed in Genesis (1:26-28) that God gave man ‘dominion over the fish of the sea, over the fowl of the air, and over every living thing that moveth upon the earth’” (Benneh, Morgan & Utto, 1996). “‘The fear and dread of you will fall upon all the beasts of the earth and all the birds of the air, upon every creature that moves along the ground, and upon all the fish of the sea. They are given into your hands. Everything that lives and moves will be food for you. Just as I gave you green plants, I now give you everything’” (God to Noah, *In:* Genesis 9:2-3, *In:* Giles-Vernick, 2002). “Consequently, it was generally believed that humans (synonymous with Europeans) had the right to exploit the natural resources of Africa and other parts of the world as desired” (Benneh, *et al.*, 1996).

“No serious effort was made to conserve natural resources until late in the 18th century when it was observed that with the extinction of the dodo in Mauritius it became necessary for measures to be taken to ensure the survival of diverse species of

organisms through the establishment of reserves. The establishment of colonial spheres of influence and the arrival of Christianity, which in some areas preceded colonial administrations, dealt a death blow to the appreciation of ecologically sound sustainable traditional or indigenous resource management strategies, practices, systems, attitudes, and behavior patterns in African culture. This was most pronounced where these practices were applied as taboos associated with traditional African religion. It is not surprising, therefore, that taboos dealing with hunting and fishing were abolished outright and in agriculture such practices as inter-cropping were regarded as primitive. With colonialism came changes in the African perspective of looking at things, Westernization, and the propensity for consumption patterns of a more materialistic kind that are satisfied only with imports of food and manufactured goods, leading to increasing dependence on the developed countries" (Benneh, *et al.*, 1996).

Thus, much of America and Africa were "conquered" by Whites through chopping down forests, fencing and creating a mosaic of rectangular landholdings. Europe's landscapes, culture and values were exported to and imposed on the rest of the world. These continents were tamed with a bible and a gun in the name of God. "The Judaeo-Christian doctrine of much of the Western world dictates that man is separate from, and master of the environment and all living things, whereas many other cultures tend to view themselves far more as an integral part of the environment" (Suchet, 1998 *In:* Roe, Mayers, Grieg-Gran, Kothari, Fabricius & Hughes, 2000). Vande weghe (2004) argues that the destruction and manipulation of traditional cultures and beliefs/rites that tempered the taking of natural resources and the adoption of a Christian philosophy encouraged over-exploitation in the name of God as both the right of man and a gift from the Creator that no one dares refuse and that is "appropriate to gather before someone else does".

3.2 WILDLIFE AS A TOOL OF CONQUEST, PLUNDERING AFRICA'S WILDLIFE RESOURCES BY EARLY EUROPEAN SETTLERS

“What a century it had been! What a shoot! There had never been anything like it before – and there would never be anything like it again. The mood was set in the first year of the 1800s when the British Governor at the Cape, Sir George Young, granted ‘liberty to all persons beyond 30 miles from Cape Town to kill game at all seasons without license or prohibition’ (*Pringle, 1982*).

Wildlife became a resource of European conquest (MacKenzie, 1997), providing income (e.g. ivory and skins) (Dorst, 1970; MacKenzie, 1997), a cheap source of meat and a means of “penetrating the country by feeding the natives” (Bell, 1923 *In: MacKenzie, 1997*) – a temporary subsidy in opening up the Continent. Wildlife was also seen to stand in the way of “Civilization and Christianity”, competing for space and pasture with livestock, its eradication being a necessary prerequisite to European imperialism. Books by explorers, ivory hunters and adventure seekers, mostly English and Scottish, many ex-military officers and royalty such as William Cornwallis Harris (1844), R. Gordon Cumming (1850), William Charles Baldwin (1863), Frederick Courteney Selous (1881), Arthur H. Neumann (1898), Arnold W. Hodson (1912), James Sutherland (1912), Owen Letcher (1913), C.H. Stigand (1913), William Finaughty (1916), W.D.M. Bell (1923) and Dennis D. Lyell (1924) promoted the myth of wild, untamed Africa, a savage land, adventure, manliness, nobility and courage. This served as a magnet to draw the hopeless European masses to this land of plenty, where with only a gun and oxcart one could get rich quickly or find wide open spaces on which to settle, where a nobody could become somebody, a luxury in over-populated and class-conscious Europe. A similar cry in the 1800s, “Go West Young Man, Go West”, encouraged European immigrants to America to seek their fortunes, pushing aside the Red Indian and slaughtering the wildlife (e.g., bison and beaver)

for meat and money with ox-cart and musket/long-rifle in seeking their fortunes. In both cases, some became rich, and many died along the way from resisting indigenes, disease and thirst (see Section 3.12, COMPARISON WITH EUROPEAN COLONIZATION OF NORTH AMERICA).

3.2.1 Wildlife as a Tool of Conquest in Southern Africa

In Southern Africa, this attitude towards wildlife resulted in the asset stripping of game, being worked out like a mineral seam (MacKenzie, 1997). In 1652, van Riebeeck reported that a French ship in Saldanha Bay had harvested 48,000 seals for their skins and oil over a six month period from around Dassen Island. By 1656, there were no more seals to be caught in that bay, taking van Riebeeck's men of the Dutch East India Company three years to harvest 48,000 seals that the French had taken in six months (Pringle, 1982).

The Africans, and Boer Afrikaner settler of Dutch, German and Huguenot descent, who often collaborated in market-hunting, saw wildlife much differently than the “sporting” English gentlemen that were to follow in their footsteps. To the Boers, wildlife had a utilitarian value for trade and food, and was viewed as an obstacle to modernization and agriculture. Boer hunting parties usually consisted of numerous armed *zwarteskutters* (black shots) or *jagtkaffers* (hunting *kaffirs*), in an equitable partnership. They could not understand how anyone could kill for pleasure, keeping only the trophy while foregoing the value of the meat and skin. Commercially valuable wildlife provided the Boers with a viable economic base, which allowed them to assert their independence as they moved into the interior to escape the ever-increasing authority of the British in the Cape (Carruthers, 1995).

Only three large mammal species in Southern Africa have been driven to extinction in the past 300 years (Cumming, 2004 *In: Child*, 2004a). The bluebok (*Hippotragus leucophaeus*) of South Africa was extinct by 1800 (Bonner, 1993), and the quagga (*Equus quagga*) by about 1870 (Dorst, 1970; Pringle, 1982; Bonner, 1993). By 1860, the Cape warthog, *Phacochoerus aethiopicus aethiopicus*, was also extinct (Grubb, 1993 *In: Oliver*, 1993).

When the Scottish hunter and adventurer Gordon Cumming began his travels in 1843 he observed, “I was astonished at the number of skeletons and well-bleached skulls with which the plains were covered. Hundreds of skulls of springbok (*Antidorcas marsupialis*) and black wildebeest (white-tailed gnu) (*Connochaetes gnou*) were strewed around wherever the hunter turned his eye” (Pringle, 1982). It is believed in the 1700s there were 500,000,000 springbok between the southernmost limits of the Karoo and the Kalahari Desert of South Africa and Namibia (Cattrick, 1959). They often migrated in herds from 100s of thousands (Skinner & Smithers, 1990) up to 10,000,000 animals (Cattrick, 1959), forming bands as much as 161 kilometers (100 miles) long by 24 kilometers (15 miles) wide in an unbroken mass. This gave the veld a whitish tint as if covered with a light snow fall (Cronwright-Schreiner, 1925 *In: Skinner & Smithers*, 1990). In the Orange Free State, in the 1870s, 1 million antelope skins were being exported annually (Mackenzie, 1997). Although the exact figures may be debated, what cannot be disputed is that these great springbok migrations had nearly come to an end by 1896, victims of guns, clubs, advancing civilization, and the cows and sheep that devoured their pasture (Cattrick, 1959).

South Africa was estimated to have had 100,000 elephants (*Loxodonta africana*) in the 1650s (Wels, 2000). In the Old Transvaal, an estimated 90,000 kg of ivory was exported in 1855 alone, as well as vast quantities of hide and horn (Carruthers, 1995). The elephant, white rhino, Cape Mountain Zebra, bontebok

and black wildebeest were on the verge of extinction in Southern Africa by the turn of the century (Dorst, 1970; African Advisory Board, 2000a), (Table 3.1).

Table 3.1 Dates and estimated numbers on the near extinction of key mega-fauna in Southern Africa				
MEGA-FAUNA	DATE	NUMBERS	SOURCE	SPECIES
Elephant South Africa (SA)	1920s	120	Hall-Martin, <i>pers. comm.</i> (1)	<i>Loxodonta africana</i>
Zimbabwe	1900	<4,000	Cumming, <i>pers. comm.</i> (2)	
Namibia	1900	300	Lindique, 1995	
White Rhino (SA)	1895	20	Emslie & Brooks, 1999	<i>Ceratotherium simum</i>

With little regard for the law and few people bothering to acquire hunting licenses, by the mid-1890s the possibility of extinction of all game in the Transvaal had become a real concern (Carruthers, 1995). By 1893, there was so little game left in South Africa that many Afrikaners had to revert to target practice to replace hunting (Bryden, 1893 *In: MacKenzie, 1997*). With the loss of most of the livestock from rinderpest, which swept down from East Africa in 1896, drought and a locust plague, the Transvaal was obliged to suspend hunting restrictions to allow the destitute public access to wildlife as a means of survival. The destruction of wildlife was condoned and even encouraged in the belief that it

was implicated in the spread of disease (Carruthers, 1995). An incredibly rich fauna was thus systematically destroyed in less than a century.

The rest of the African subcontinent followed, large mammals vanishing with the advancement of European civilization (Dorst, 1970). Even as late as 1917, hunters flocked to Natal in a free-for-all slaughter of wildlife to clear the bush of tsetse fly and the carriers of sleeping sickness so that cattle could be maintained. An estimated 25,000 (blue) wildebeest (*Connochaetes taurinus taurinus*) alone were exterminated in a single campaign. In 1929, 15,130 zebras were exterminated, the total numbers of wildlife killed in the name of tsetse control amounting to 138,529 (Rosenblum & Williamson, 1987). This slaughter continued into the 1950s when chemical traps and biological control were able to virtually wipe out the tsetse fly in South Africa (Rosenblum & Williamson, 1990). In attempting to control the tsetse fly, nearly a million head of wildlife were removed in Zimbabwe, a process that continued into the 1970s (Bond, Child, de la Harpe, Jones, Barnes & Anderson, 2004 *In: Child, 2004a*) (also see Chapter 7, Section 7.8.10.2, Kariba Reservoir, Zimbabwe, Zambezi River). It was only after wildlife had served its role as a subsidy of conquest that the colonial powers began to restrict the harvest of wildlife for “sport” (MacKenzie, 1997).

Southern Africa was not alone.

3.2.2 Wildlife as a Tool of Conquest in Francophone Africa

Hunting casts (guilds, *confréries de chasseurs*) existed among all tribal groups (see Chapter 2, Section 2.1.6, Hunting Guilds as a Means of Controlling Access to Wildlife). They provided meat for the community managed as a “*Common Property Resource*”. Apprenticeships limiting access, taboos, totems and primitive weapons made over-harvest difficult. The coming of the Europeans and their modern firearms resulted in a slaughter of the game: 1) to feed workers in

“developing” and opening up Africa, and 2) for commercial purposes (Tré-Hardy, 1997; Giles-Vernick, 2002). It is estimated that between 1608 and 1612, 23,000 kg/year of ivory was imported to Holland alone, mostly from West Africa (Wels, 2000). In 1909, just one forest concessionaire, the N’Goko-Sangha Company from the Sangha Basin of French Equatorial Africa/*Afrique Équatoriale Francaise* (AEF), exported 6,625 kg of ivory. When another company, *Compagnie Forestière de la Sangha-Oubangui* (CFSO), took over this concession, its annual exports fluctuated between 2,694 kg in 1911 to 4,105 kg in 1917 (Giles-Vernick, 2002). Ivory exports from German *Kamerun* (Cameroon) were valued at US\$ 5 million (530,000 *reichsmarks*) in 1914, while at the same time in German East Africa (modern Tanzania) exported ivory was valued at only US\$ 3.4 million (360,000 *reichsmarks*) and US\$ 400,000 (40,000 *reichsmarks*) from Togo. The peak export of ivory from Kamerun was valued at US\$ 10 million (1.27 *reichsmarks*) in 1905 up from an average of US\$ 8.5 million/year (900,000 *reichsmarks*/year), a consequence today being that Cameroon has few if any big tuskers (von Meurers, 1999), making one wonder if such harvests resulted in elimination of the genetic trait for large tusked elephants. Between 1937 and 1939, 200,000 elephants were killed in the Belgian Congo (today’s Democratic Republic of Congo) for ivory (Wels, 2000). As late as 1953, 750,000 skins, chiefly duiker were exported out of the French Union in Africa (Marty, 1955 *In:* Dorst, 1970). It is estimated that 2 million duikers were being killed annually for their hides in Francophone Africa south of the Sahara during this same period (Dorst, 1970). One concessionaire in the Sangha Basin, *Maison Coulon et Wiart*, exported 10,351 antelope (most likely duiker since this is largely a forested environment) skins in the second trimester of 1934 to as many as 33,248 in the final trimester of 1935 (Giles-Vernick, 2002). Wildlife became an “open access” resource in which harvests went uncontrolled. This same “*get rich quick*” mentality is believed to exist today in the exploitation of Central Africa’s timber and bushmeat resources.

3.2.3 Wildlife as a Tool of Conquest in East Africa

In colonial Kenya until 1976, there was a legitimate trade in valuable skins such as leopard and zebra, legally harvested by landowners from animals killed in defense of property. During WWII, zebra and wildebeest were harvested to feed prisoners-of-war; the first time that sustainable harvesting of large numbers of plains game was proven feasible (Blankenship, Parker & Qvortrup, 1990).

“When Germany, a latecomer to European colonial expansion, declared Tanganyika a Protectorate in 1885, the slaughter of the elephants had already surpassed its peak and elephants were becoming rare. Two hundred tons of ivory was exported every year from Zanzibar, the equivalent of some 12,000 elephants. Commercial hunters could buy licenses to shoot elephants for their ivory” (Baldus, 2005 *In:* Baldus, 2005).

From 1903-1911, a total of 256 tons of ivory was exported from Tanganyika (today’s Tanzania), representing approximately 1,200 to 1,500 elephants killed/year with the likelihood that significant amounts of ivory were smuggled out of Tanzania on *dhow*s in order to avoid the 15% export tax of the Kaiser. During this same period (1902-1911), 53 tons of rhino horns were exported, representing 2,000 to 2,300 rhinos shot/year, while 1,000 live animals, 50 tons of antelope horns and 2.7 tons of valuable bird feathers were exported to Germany (Baldus, 2001).

In Somaliland alone 350,000 dikdik skins/year (*Madoqua sp.* and *Rhynchotragus sp.*) and about 70,000 antelope skins/year were exported, 80% of which were giraffe (*Giraffa camelopardalis reticulata*), gazelles (*Gazella spp.*) and gerenuk (*Litocranius walleri*) (Funaioli & Simonetta, 1961 *In:* Dorst, 1970). Even as early as 1905, Commissioner E. J. Swayne observed a major decline in game populations, not attributed to disease or native hunting but modern rifles used

mostly by 500-600 European sportsmen and military officers and their *Sepoys* (soldiers from India), who shot as much as they wished (MacKenzie, 1997).

3.2.4 Other Causes for Decline in Wildlife

Between 1889 to the early 1900s, the rinderpest epidemic nearly wiped out buffalo, giraffe, eland, etc. in East and Southern Africa (MacKenzie, 1997) (see Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya).

3.3 PERCEPTION THAT AFRICANS WERE THE CAUSE FOR WILDLIFE DECLINE

“Thus although Africans themselves played no direct part in shaping the conservation laws which were framed in the early 20th century Transvaal, white perceptions that Africans destroyed vast numbers of wildlife, that they trespassed in order to do so, that they killed in a cruel manner, that they spoilt the recreation of sportsmen and managed to evade wage labor by subsisting on wildlife, determined to a considerable extent the kind of protectionist ethos that emerged” (Carruthers, 1995).

Beinart (1989, *In:* Fabricius, Koch & Magome, 2001) draws similar conclusions, namely that biltong hunting by poor whites and Africans was perceived as laziness and a desire to avoid wage labor.

The perception of the colonial masters was that Africans were the reason for declining wildlife numbers (MacKenzie, 1997; Carruthers, 1995, Adams, 2003 *In:* Adams & Mulligan, 2003). Even though Africans had co-evolved with wildlife as described in Chapter 1 (Section 1.3, CO-EVOLUTION OF MAN AND WILDLIFE IN SUB-SAHARAN AFRICA) and had sustainably used their wildlife for 1000s of years (see Chapter 2, Section 2.1, TRADITIONAL

HUNTING AND WILDLIFE MANAGEMENT), the colonial powers failed to recognize that it was the coming of the European, with superior technology, the “modern firearm”, and the commercialization of wildlife in a way that Africa had never seen, along with his desire to have dominion over nature (e.g., fencing the land, conversion of natural systems into cultivated land and competition with livestock for pasture) that brought a number of species to extinction or near extinction. This was eventually compounded by the human and corresponding livestock population explosions on the subcontinent in the 20th century.

However, in the early 1900s game wardens of the British East Africa Protectorate (Kenya) were concerned that European settlement, not rural Africans, whom they considered co-existing with wildlife, were the real problem, “...it was no longer possible to continue the compulsory preservation of large herds of gregarious species of game on the areas which were occupied by white colonialists...If success is to be attained, it is essential that the regulations dealing with the preservation of game should meet with the approval and support of the body of colonialists who have to live under such regulations...” (ANON, 1911 *In: Blankenship, et al.*, 1990). By the 1909 Game Ordinance, landowners were allowed to destroy animals competing with them, and indigenous people reliant on wildlife for food were allowed to continue traditional hunting (Blankenship, *et al.*, 1990). Only hunter gatherers were allowed to hunt game, while it was considered regressive for African agriculturists and pastoralists to hunt (MacKenzie, 1997) without any regard for cultural ties to the hunt or game as a hedge against disease and drought. However, according to Blankenship, *et al.* (1990) indigenous people were never accorded the liberal policy implied in this ordinance, later ordinances completely ignoring their traditions, with Africans being blamed for the demise of wildlife. “Every African is a poacher...in Kenya one recognizes no customary hunting rights though certain sub-tribes such as the Tharaka in Kitui, the Teita in Voi and the Wasanye (Waliangulu) in the Coast

Province, not to mention the forest dwelling Dorobo are nearly all full time hunters" (ANON, 1955 *In Blankenship, et al.*, 1990). Since about 1920, despite the importance of subsistence hunting, people in Kenya were prosecuted for poaching, while licensed hunting was too expensive for most Africans and access to modern firearms was greatly restricted (Blankenship, *et al.*, 1990).

In French Equatorial Africa/*Afrique Équatoriale Française* (AEF) after 1910, colonial officials began to express concern over the fate of game. By 1930, Saint Floris, the inspector for hunting in the AEF raised concern that elephants had nearly disappeared in the AEF, while exploitation continued despite the lack of big tuskers. Africans were blamed for this over-hunting, and not the private commercial companies mining the region's rubber, ivory, skins, soils and eventually timber, who used and exploited Africans to harvest game (Giles-Vernick, 2002).

Similarly, excerpts from James Stevenson-Hamilton (1937) describe South Africa's lowveld hunters of the late 1800s operating in and around today's Kruger National Park as far from being ethical and a major reason for the decline in wildlife.

"Among the real old timers of the low-veld, of whom Bill Sanderson was typical, no characteristic was so prominent as was the pride which they took in their skill with the rifle. They were as proud of their shooting powers as any society belle of her personal attractions, and were as jealous of their rivals in this respect as a young man might be of a competitor in love. You might asperse their morals, their personal appearance, even their honesty, and be pardoned; but to cast a slight on their marksmanship was an insult not to be forgiven. Men of both British and Dutch race were numbered among these old hands...Their methods were not always such as recommend themselves to sportsmen; they had seldom regard for sex or age, or for the number of animals they might kill, in fact the main consideration was the largest number killed in the

shortest time, with the least expenditure of ammunition, subject to it being deemed unbecoming to fire at any but a running buck...All these old hunters (Erasmus, the Glynnss, Schoeman, etc.) were invariably equipped with the best and most modern of breechloading firearms, in those days Westley Richards and Martini-Henry falling block or double-barreled express rifles, firing black powder. Smokeless powder and magazine small-bore rifles had not yet come into use – happily for the game, which otherwise would no doubt have been entirely exterminated, for all were magnificent shots, splendidly mounted and quite ruthless in their methods, while trek Boers who came down in large numbers each year for winter grazing, also shot everything they could come across...There was no hunting ethics whatever. If a man did not succeed in killing an animal he had fired at, the next best thing for his own glorification was to have wounded it. 'Well I did not actually get anything to-day, but I wounded a lot of them,' was quite an ordinary remark to hear in a bar in 1902...Buffalo were the most profitable game, and as they were numerous in fly country, it was against them that the chief efforts were directed...Professional hunters in the old days had no use for lions as game; the skins having no marketable value, they were regarded merely as vermin, killers of creatures which should rightfully belong to the human predatory animal; when shot, they were generally left where they fell".

3.4 DEVELOPMENT OF AN ENVIRONMENTAL CONSCIENCE AND EXCLUSION OF AFRICANS FROM LEGALLY ACCESSING WILDLIFE

"African communities have hunted for many years. One could even say we were the first hunters. However, over the last two centuries the colonial governments outlawed the way we hunt, as they took control of our natural resources. It must be remembered that it was only after the arrival of white hunters with their vast firepower and greedy hunting zeal that we needed to create protected areas to stop the killing to extinction of the big five" (RSA Community Organizations, 2005).

Once the scramble for Africa was over and the continent had been carved up, it belonged to everyone but native Africans. At the beginning of the 20th century,

an “*environmental conscience*” began to develop and the European, especially the British ideas of “*sporting*” and “*fair chase*” were put forth upon which eventual game laws would be based.

The culture of hunting in Europe was turned into part of the culture of European Imperialism in Africa. This imperialism was largely masculine and elitist, symbolized by the “mounted trophy” from the hunt. The taking of life through hunting was viewed as a necessary training for European conquest and war (MacKenzie, 1997). Hunting was also closely connected to the study of natural history, with expeditions collecting specimens from the imperial world for “European” museums and taxonomists (MacKenzie, 1997).

European imperialism also excluded Africans and their traditional hunting methods as “un-sporting”, and “not fair chase”, failing to recognize that the Africans had always conserved wildlife and habitat as part of their cultural heritage and survival network (see Ethics below).

3.4.1 Centralized Control of Natural Resources and the Arrival of Conservation

Subjecting natural resources to some measure of central control has been an important element in the establishment of most Western states and in the formation of colonial states in particular. Such interventions have been designed to regulate use, to privilege access for particular, often dominant, social groups (in colonial times European settlers, today Western NGO’s and rich tourists from America and Europe) and in some cases to conserve resources. This has cut across existing patterns of resource use and conceptions of legitimate access (Beinart, 2002a; 2002b both *In:* Dovers, Edgecombe & Guest, 2002; Murombedzi, 2003b *In:* Adams & Mulligan, 2003).

Beginning in the colonial era and continuing into independence natural resources, including wildlife and related habitat were

“incorporated into the public domain of the state, such as national parks and protected areas (e.g., game and forest reserves, hunting blocks), as well as water resources. Here, administration and usage is exclusively in the state’s hands (Kirk & Adokpo-Migan, 1994 *In: Kirk, 1997 In: McCarthy, et al., 1997*), which has led to a well-documented ‘tragedy of the state’ (Baland & Platteau, 1996 *In: Kirk, 1997 In: McCarthy, et al., 1997*) - with resource plundering, only rudimentary management and enforcement capacities, and thus high transaction costs” (Kirk, 1997 *In: McCarthy, et al., 1997*, Excerpted with permission from the International Food Policy Research Institute).

The colonial masters of England, France, Belgium, Portugal and Spain signed the first international conservation treaty in 1900, “The Convention for the Preservation of Animals, Birds and Fish in Africa”. The goal of this treaty was to save African wildlife for hunting by royalty and upper class Europeans, and for ivory. Its objective was to protect the elephant and wildlife from Africans (Bonner, 1993).

“It soon became apparent that nationalization undermined customary tenure regimes without replacing them with comparably effective systems of state management and administration” (Kirk, 1997 *In: McCarthy, et al., 1997*). Africans had their traditional governance and resource management systems usurped by Western laws. Traditional hunters and resource exploiters were turned into poachers (Crush, 1980 *In: Fabricius, et al., 2001*) and alienated from these imposed management systems.

The degradation of wildlife and its habitat was used by colonial officials to justify conservation. In the case of wildlife this meant the creation of parks and

protected areas given over to government game wardens and “Great White Hunters”, while in forestry, this justified the transfer of user rights from local communities to extractive firms. In almost all cases, wildlife conservation meant the expulsion of Africans from territory to be preserved and the almost complete extinction of African user-rights to the resources. Colonization of the South (e.g., tropics) by European powers in the 18th and 19th centuries and the accompanying spread of conservation did not bring with it this respect for traditional rights (Colchester, 1994 *In: Roe, et al.*, 2000).

The concept of modern day parks had a lot to do with John Muir, founder of the Sierra Club in America (see Section, 3.12.3, Beginning of the Green Movement) although this is an Anglo-Norman concept dating back many hundreds of years (see Section, 3.4.2, Origin of Parks and Game Reserves). The model for wildlife conservation that was globally adopted was based on the American approach with local people's traditional rights of use and access classed as poaching and encroachment (Colchester, 1994 *In: Roe, et al.*, 2000).

3.4.1.1 Cape Colony, South Africa – some of the earliest legislation

Being the main land base for European expansion in Southern Africa and settled since the mid-1600s, the Cape Colony was one of the first places in Africa to experience wildlife depletion from over-hunting and the expansion of civilization – Europeans and their agrarian systems. By 1822, the Cape Colony had enacted sophisticated hunting restrictions including: 1) closed seasons, 2) special protection for elephant, hippopotamus and bontebok, 3) restrictions on killing pregnant and immature animals, 4) stringent anti-trespassing provisions, and 4) embryonic state game reserves (Carruthers, 1995).

The Game Law Amendment of 1891 and the Game Preservation Ordinance Act of 1899 brought about the end of frontier exploitation by adventurers like ivory hunters in Southern Africa (Bond, *et al.*, 2004 *In: Child*, 2004a; Murombedzi, 2003a). Though passed in the Cape of Good Hope (a British colony), the game legislation was imposed on the British South African Company (BSAC) in its charter by the imperial state. Thus the game laws would be applied to the (BSACs) territory, later (in 1923) to become Northern Rhodesia, Southern Rhodesia and Nyasaland.³⁰ “The ordinance further declared elephant, giraffe, hippopotamus, white rhino, eland, zebra, Burchell's zebra, quagga, kudu or ostrich royal game and prohibited their killing, hunting pursuit or capture, unless they were bona fide required for scientific or farming purposes” (Murombedzi, 2003a). A closed season was established linked to breeding (October 30th-April 30th). Hunting required the purchase of game licenses; “A” for general hunting during an established season, while game on a “B” license required special permission before hunting (royal game such as elephant). Certain wildlife controls were allowed as a means of regulating disease linked to game and predators. A species could be protected from hunting for a period of up to five years in order to allow its population to rebuild. People traveling through the area, such as farmers and police, were exempt from the ordinance and allowed to hunt game to feed themselves if they were 20 miles or more from a town. However, the meat could not be brought to town and sold commercially. This also made it easier for farmers to undertake vermin/disease control. The taking of game by policemen was considered excellent training for military/war (Murombedzi, 2003a). Many of these laws were poorly enforced (MacKenzie, 1997).

³⁰ The BSAC charter was granted to John Cecil Rhodes in 1889. The BSAC handed over its territory to Britain in 1923. In 1953, the Federation of Rhodesia (North and South) and Nyasaland was created. This did not include Bechuanaland (Botswana) or the *Zuid-Afrikaanse Republiek* (Transvaal) or Orange Free State.

3.4.1.2 Centralization of control over wildlife, South African Republic

With the creation of the semi-unified Transvaal, consisting of five autonomous republics that became unified in 1853, concern was already beginning to take hold that the resource driving the economy, wildlife was rapidly being depleted like a seam of gold being played out. In 1846, the Volksraad (parliament) of the Andries Ohrigstad district passed a resolution exhorting *burghers* (citizens) not to kill more wildlife than one could use at any one time (Carruthers, 1995). By 1858, the wildlife economy of the Old Transvaal had begun to suffer from the depletion of game, resulting in the passage of the first hunting legislation in the *Zuid-Afrikaansche Republiek* (South African Republic). Its objectives were: 1) sustainable use of wildlife as a means of perpetuating economic welfare and security of the state, 2) as wildlife was becoming less abundant, to start controlling and restricting African access to wildlife and firearms unless under the control of a white, 3) reducing the African communities' ability to live from wildlife as a means of forcing them to become laborers on white-owned farms and mines, and 4) disarming "bands" of Africans who could have posed a military threat to the nascent Transvaal Boers. The law failed at the time due to the white's dependence on wildlife and the hunting power of their black colleagues (Carruthers, 1995), but it was ominous of things to come as sedentarized farming, urbanization and industrialization took over from the semi-nomadic lifestyle of the market hunter - similar to the buffalo hunters and beaver trappers (mountain men) in North America - who had opened up and provided access to the "Wild West" of Southern Africa – the Old Transvaal – which would become the gateway for European hegemony over the rest of the region.

By the 1860s, the landholding and urbanized elite began to take on "British" attitudes of recreational "sport" hunting that conflicted with those of the black and white market hunters. In 1870, new legislation was passed incorporating the 1858

legislation, in addition to recognizing the need for state gamekeepers to enforce the law, and the need to further restrict traditional black hunters by outlawing trapping. The belief in “hunting for pleasure” as being ethical and hunting for the market as “cruel” was reinforced with the annexation of the Old Transvaal by the British in 1877 (see Ethics, below). Seen as a loophole to conservation, the clause allowing whites to hunt (‘sufficient for one’s own consumption’) was changed against the wishes of the President of the Boer Republic, Paul Kruger, to an annual quota of 15 large head of game and 20 head of small game per hunter (Carruthers, 1995). In fact, Carruthers (1995) depicts Paul Kruger as being anti-preservationist, exuding the utilitarian “biltong” hunter mentality of his pioneering generation, far from being the “Father of National Parks” and the founder of the renowned “Kruger National Park”. This folklore was eventually useful in the late 1940s in creating the political movement of Afrikaner Nationalism. In other words, Kruger was a proponent of conservation (sustainable use as personified by hunting blocks/game reserves) over preservation (protection/no use as personified by parks).

3.4.1.3 Centralization of control over wildlife, Northern Rhodesia (Zambia)

First under the British South African Company (BSAC) in the late 1800s and then as the British colony of Northern Rhodesia in 1924, gaining control over wildlife was central to the plans of Northern Rhodesia’s (Zambia) colonial administrators. Despite the decimation of wildlife populations due to an outbreak of rinderpest, the British were convinced that the major cause for this decline was excessive hunting by Africans with black powder muskets.

The colonial administrators, in this case the British South African Company (BSAC), undermined the authority of the chiefs. The BSAC sought to dominate the lucrative ivory trade in the late 19th and early 20th centuries. The chiefs were

obliged to enforce European regulations, which decreased their popularity among Zambians, who had already witnessed the chiefs' impotence to stop white colonization (Gibson, 1999).

The BSAC struck at the heart of the chiefs' control over wildlife, and the access to wildlife by rural Africans. Africans were not allowed to own guns or powder (Marks, 1984) while areas designated as game reserves were declared off limits to Africans, and hunting restrictions such as quotas, game licenses, etc. were published under the 1925 Game Ordinance. The government assumed complete jurisdiction over all natural resources, and land use.

3.4.1.4 Centralization of control over wildlife, Southern Rhodesia (Zimbabwe)

Government appropriated formal control over all wildlife, providing hunting rights to resident whites and visiting sport hunters. Blacks, through hunting and firearms restrictions, were almost totally excluded from any legal use of wildlife. For communal land farmers, wildlife became a liability except for those who were willing to risk unsanctioned exploitation as "poachers". Even for the white owners of farms and ranches, wildlife was often seen as competition to crops and livestock, and thus eliminated illegally. Parallel to this alienation of wildlife from farmers, the state also created "game reserves" which were to form the basis of the parks and wildlife estate of today, covering 12.5% of the Country's land surface (Murphree, 1997); 14.72% in 2004 (see Chapter 11, Section 11.10.6.3, Few success stories with the 10% factor).

3.4.1.5 Centralization of control over wildlife, East Africa

By 1891, the first hunting regulations were issued in the Moshi District, Tanganyika, six years after it had been declared a protectorate. The first general wildlife ordinance for the then German East Africa dates back to 1896 and was issued by Hermann von Wissmann, the imperial governor, to avoid the extinction of species and to assure future generations “ ‘...the chance to find leisure and recreation in African hunting in future times’ ” (Baldus, 2001). At this time, the Governor announced plans to establish wildlife reserves for controlled hunting. “European settlers and hunters were quite frustrated by their own Government, which only interfered with traditional hunting by the local African population when it was seen as commercial” (Baldus, 2001). Commercial culling viewed as the biggest threat to wildlife, was stopped in 1911, while the concept of “*sustainable use*” or “sustainable offtake of wildlife” was evolving as a term. Hunting licenses could be obtained by indigenous Tanzanians, non-indigenous residents and visiting nonresidents with fees differing accordingly. Landowners could kill problem animals, but skin horns and tusks had to be turned in to government. All predators including lions, leopards, wild dogs or crocodiles were considered pests and could be killed on sight and for reward (Baldus, 2001).

Parker (2004) notes that natives were disallowed from hunting in white dominated Anglophone Africa, namely Kenya, Southern Rhodesia and South Africa (including what is now Namibia) as a security measure to keep firearms out of black hands. Access to firearms and the right to hunt was less rigid in non-white Anglophone Africa, with the majority of elephant in Uganda taken by African license holders and native game licenses being introduced by 1940 in Tanganyika (Tanzania) (Parker, 2004). However according to Majamba (2001), Section 28 of the Game Ordinance of 1940 allowed traditional hunting in Tanganyika for the purpose of acquiring food but without a firearm, and special permits were

required for certain species. It did not take into account hunting for specific species for cultural and traditional rituals. Local hunting tribes, including the WaTindiga, the Bahi and the Wanderobo who lived with wild animals did not require a hunting license under section 12 (ii) of the Fauna Conservation Ordinance.

“The selectivity in having in place legal provisions that permitted some community members to practice their cultural and traditional rituals pertaining to hunting while denying others reflects the application of the ‘divide and rule’ concept. This strategy was constantly applied by colonial administrative regimes to divide local inhabitants in order to ensure their continued control while using their labor to plunder the economies for the benefit of the Metropolis” (Majamba, 2001).

3.4.1.6 Centralization of control over wildlife, French Equatorial Africa/Afrique Équatoriale Française (AEF)

By 1916, the French administration introduced measures to protect big game from over-hunting in Africa. It was recommended that the hunting by *Babingas* (Pygmies) be monitored and that all Africans be prohibited from using guns. The view that the crocodile, leopard, hippo and rhino were pests was later amended to place the rhino and buffalo on the list of protected species. By 1929, AEF began issuing hunting permits. Eventually game was classified under small game (*petite chasse*), medium game (*moyenne chasse*) and big game (*grande chasse*) for sport hunters, plus commercial and native (*indigene*) hunting with the issuance of corresponding permits. Eventually, Africans were forbidden to use fire and poison to hunt and had to purchase a permit allowing the hunting and trapping of all unprotected wildlife. Big game commercial and sport hunting permits and selected native permits allowed hunting of protected big game species including elephant, hippo, forest buffalo, gorillas, bongo and sitatunga in the forest. Africans were allowed to have hunting arms but had to pay annual taxes and, as

noted, were extremely limited in what they could harvest legally. When given permission to hunt valuable species such as elephant for commercial purposes, Africans were taxed one tusk for each elephant harvested. However, it is believed that many Africans, as today, were not fully aware of these laws and/or chose to ignore them. In many cases, the logistics of going to a regional administrative town was just not practical. Finally, as all over Sub-Saharan Africa, French hunting laws usurped the traditional authority of chiefs, hunting guilds and “master (*tuma*) hunters”, who in the past controlled access to the to wildlife at the local level. This created a dual management system, namely a centralized one favoring white administrators, merchants, missionaries and in recent times “experts and technical assistants”. These centralized systems of control lacked the manpower at the local level to enforce their laws, while the traditional management systems that worked well at the local level were marginalized, forcing many Africans into poaching what they felt belonged to them (Giles-Vernick, 2002), thereby creating unmanageable “open access” resources that were mined by all for short-term gains.

3.4.2 Origin of Parks and Game Reserves

The concept of parks and game reserves carried by the European as he invaded the rest of the world dates back to the Normans (Franks) in the seventh century (Gilbert, 1977 *In:* MacKenzie, 1997). The Norman hierarchies and their complexities of forest law were more concerned with sport, class privilege and assertion of royal status than food supply. The king and his delegated officers had sole right of access to the forest with five animals reserved exclusively for their use; hart and hind (red deer), hare, boar and wolf (MacKenzie, 1997). The “chase and park” areas of unenclosed and closed land were preserves of the Norman lords who held the franchises for the hunting of buck and doe (fallow deer), fox, martin and roe (MacKenzie, 1997). It is interesting that the proletariat, upon the

fall of the Bastille, turned the wildlife back to the people – something that is written and mentioned even to this day in French game laws.

Meanwhile, the poor, the starving and landless peasants who were pouring out of an over-populated Europe into Africa and the New World, among others, imposed the very same laws, which had oppressed them on the indigenous peoples of these lands, which for the most part are still the laws of the land in most of Africa in the 21st century. They took away or greatly restricted the right to hunt and created “Norman/Sherwood Forests” in Africa and the USA and in many other places where they settled, disenfranchising the indigenous peoples and turning parks, game reserves and associated wildlife into resources available to the elite of the colonies, and which the African then and now must still access clandestinely. What had been rejected by “Robin Hood and his Merry Men” in Europe was expected to be accepted by Africans!

“As alarm about the decline of animals increased in the 1890s and the early years of this century, European hunters produced an apocalyptic vision which often produced equally apocalyptic solutions: the creation of vast reserves and national parks, the movement of peoples (out of parks and reserves), widespread culling of both domestic and wild animals, particularly so-called vermin, and the imposition of hunting bans (on Africans) that were highly culturally determined. Ultimately, many of these policies were as disastrous, to the interests of both humans and animals, as the problems they were designed to overcome” (MacKenzie, 1997 *In: Griffiths & Robin, 1997*).

Carruthers (1995) comes to similar conclusions regarding the application of these policies in South Africa. The African was blamed for the demise of wildlife, even though much had to do with the indiscriminate slaughter of wildlife for profit by the Europeans, and so the cure was imposed on Africans, separating them from the very resources on which they depended for survival and cultural purposes.

Parker and Amin (1983) best express these origins:

“The history of conservation in East Africa (Uganda, Kenya and Tanzania) over the past 90 years is a ‘bastard product of a union between one thousand years of Anglo-Norman game keeping and 19th century economic imperialism.’ Initially, the economic incentive to preserve game was directly tied to a desire to secure monopolies over ivory trading. The outward form of the laws was English history repeated. Instead of a Royal House and aristocracy enforcing their will on lowly Britons, the East African laws regulated the sport of imperial gentlemen at the expense of the indigenous people”.

3.4.2.1 Creation of parks and game reserves in Africa

“What the sportsman wants is a good trophy almost invariably a male trophy and the getting of that usually satisfies him...The position is not the same with the native hunter. He cares nothing for the species or trophies or sex, nor does he hunt for the fun of the thing” (Hingston, 1931 *In:* Adams, 2003 *In:* Adams & Mulligan, 2003).

In East Africa, many administrators and some settlers belonged to a higher social class than in Southern Africa (e.g., Lord Delemere), coming from the British and German elite/aristocracy and interested in conserving wildlife for “the hunt” which in Europe was reserved for the elite of society (MacKenzie, 1997; Adams, 2003 *In:* Adams & Mulligan, 2003). “Safari hunting” was born in East Africa where wealthy tourists paid dearly to be guided by professional “Great White Hunters;” what MacKenzie (1997) calls the “elite hunt”, as opposed to “traditional hunting” and “commercial hunting”.

“Game reserves” tended to be places for the European and American elites to hunt (MacKenzie, 1997; Carruthers, 1995). Game reserves were established in Kenya in the 1800s for hunting (MacKenzie, 1997 *In:* Griffiths & Robin, 1997). By the

early 1900s, Kenya was divided into three classes or land uses (Anon, 1911 *In: Blankenship, et al.*, 1990):

- Occupied Areas, inhabited by white settlers, who by the game ordinance owned the game on their land, and seen as areas where wildlife would likely disappear;
- Game Reserves³¹, over an absolute sanctum for wildlife; and
- Game Preserves, consisting of Crown Lands, closed districts and native reserves, all for shooting expeditions.

In Kenya, game regulations encouraged sport hunting, contributing a significant portion of the revenue to the protectorate. As early as 1910, the Kenyan Game Department income from licenses was £ 10,000/year (ANON, 1911 *In: Blankenship, et al.*, 1990). Many Africans, such as the Wakamba, were cut off from legally accessing the wildlife that they had traditionally hunted (MacKenzie, 1997). “Sport” hunting really took off after WWII when traveling became more affordable (Blankenship, *et al.*, 1990) and continued until its ban in 1977 in Kenya. It was made famous by novelist hunters such as Ernest Hemingway and Robert Ruark and U.S. President Teddy Roosevelt. In 1966 sport hunters to Kenya spent K£ 864,200 (US\$ 2,333,340) (Clarke & Mitchell, 1968 *In: Blankenship, et al.*, 1990). By 1972, photographic tourism in Kenya’s parks had become one of the top three money earners, bringing in US\$ 71.6 million, though by the late 1980s, it was estimated that wildlife was contributing 50% and Kenya’s beaches the other 50% of revenue from ecotourism (Blankenship, *et al.*, 1990).

³¹ Observe this term (reserve) and the next term (preserve) were either mixed up or the names eventually changed as game reserves became hunting areas over much of the 20th century, including in Tanzania. National parks became sites for preservation. Game reserves in South Africa in the 21st century may or may not be used for sustainable use at the discretion of the province.

In order to conserve wildlife the Government of Tanganyika had by 1911 officially declared 15 protected areas totaling approximately 30,000 km² or 5% of the colony. Some argue that as early as 1896, game reserves had been established north of the Rufiji River (now Selous) and on the west side of Mount Kilimanjaro (Baldus, 2001).

As is seen throughout this book, very little of the money from wildlife went/goes to the rural communities (see Chapter 9) who had co-existed with wildlife up until the arrival of colonialism. Increasing human populations in the 20th century with no concurrent benefits have put Africans in continual conflict with wildlife; many opting for other land uses as a means of survival since wildlife had/has lost its value economically and in many respects culturally.

Some of the oldest game reserves in Africa are the Groenkloof (1822) and Knysna (1856) in the Cape Colony, the Transvaal (now part of KwaZulu-Natal) Pongola Game Reserve (1894) (Carruthers, 1995), and the Tsitsikamma Forests in the Cape declared a game reserve in 1886 (Child, 2004b *In:* Child, 2004a). The Pongola Game Reserve played a strategic role in providing the Boer Republic access to Pongolapoort (port) at the mouth of the Pongola River, so as to allow it to be free of British intelligence and control. Though the strategic (militarily) and political role of this game reserve was more important at the time than “preservation”, it was the first time the Transvaal had set aside land which would exclude the public and disallow hunting (Carruthers, 1995). In essence, one could argue that this was one of South Africa’s first parks or exclusion zones.

In the South African Republic, after rinderpest and the accompanying extermination of wildlife, game reserves were created where vast tracts of government land around townships were declared closed to hunting for five years.

By 1889, the Volksraad gave the President of the Boer Republic authority to establish game reserves by proclamation, though proclaimed reserves did not enjoy the same legal status as statutes passed legislatively and could be repealed at any time. By 1902, the Transvaal decreed that game reserves were for sportsmen, and as antelope populations increased, hunting would contribute to the economy, as those who wanted the privilege of hunting would have to pay for it (Carruthers, 1995). The movement towards creating conservation areas marked a major change from the pioneering market and biltong hunters to one of a landed and urban elite. British culture also began to direct the politics of the emerging South Africa state (Carruthers, 1995).

In the final years of the South African Republic (e.g., before being taken over in 1910 by the British as the Union of South Africa), there was a major shift in thinking from legislation to conserve game countrywide through “sustainable use” towards legislation advocating rigorous preservation in the creation of game reserves. These reserves had the initial impact of removing depleted wildlife resources from the economy (Carruthers, 1995). The Sabi Game Reserve was established in 1898. It was rechristened Kruger Park in 1926, the first national park in Anglophone Africa.

The oldest African park, Albert National Park was established in the Belgian Congo (today's DRC) in 1925 to protect the mountain gorilla (*Gorilla gorilla beringei*). According to MacKenzie (1997), the Belgians took over from the Germans in prodding the English to create parks, which the English believed to be premature in their colonies, especially East Africa. By 1934, several hunting reserves and parks had been established in the Ubangi-Shari and Chad areas of French Equatorial Africa/*Afrique Équatoriale Française* (AEF) (Giles-Vernick, 2002). In Kenya, Lord Delamere was the first to push for the establishment of parks in 1900. In 1940, the first park was created in East Africa when the

Serengeti was upgraded from a reserve (where hunting could take place) to a national park (Bonner, 1993).

The momentum to create “national parks” in British Africa began in 1930, when Britain’s Society for the Preservation of the Fauna of the Empire sent a Major R. W. G. Hingston to look at wildlife conservation in Britain’s Central Africa colonies of Northern Rhodesia (Zambia), Nyasaland (Malawi), Tanganyika (Tanzania), Kenya and Uganda. He advanced ethical and moral as opposed to utilitarian motives for the formation of parks based upon a dual objective: 1) preserving nature and 2) doing so while not inconveniencing man. This could be accomplished by separating man from wildlife that is by establishing national parks, which excluded local people from living within the boundaries of the park. Hunting would be prohibited. Hingston believed the white rhino, gorilla, nyala and Grevy’s zebra to be on the verge of extinction, projecting their disappearance in 50 years without protection. The main causes were alleged to be: 1) cultivation, 2) trade, 3) hunting (exonerating the European while blaming the African) and 4) the menace of disease. Hingston believed there would be “‘no permanent solution’ ” to problems of crop and stock, of disease and the hunting instinct, until “‘the human life and the wild life are separated into two completely distinct compartments’ ” (MacKenzie, 1997).

In 1933, an International Conference for the Protection of Flora and Fauna of Africa, held in London, laid down the principles on which national parks were to be established, being defined under Article 2 as an area:

1. Placed under public control. The boundaries of which shall not be altered or any portion [thereof] be capable of alienation except by the competent legislative authority;

2. Set aside for the propagation, protection and preservation of wild animal life and wild vegetation, and for the preservation of objects of aesthetic, geological, pre-historical, archeological or other scientific interest for the benefit, advantage, and enjoyment of the general public; and
3. In which the hunting, killing or capturing of fauna and the destruction or collection of flora is prohibited except by or under the direction or control of the park authorities; thus “preservation” as opposed to “sustainable use” and “conservation”.

Human populations were moved off of and denied access to their traditional hunting grounds, burial sites, sacred forests, etc. This resulted in further alienation of Africans from these Western management systems, forcing them into clandestine parallel black markets and making it difficult if not impossible for colonial and then post-independence governments to sustainably manage resources in these parks.

For instance, in Northern Rhodesia (Zambia), vast tracts of land were declared protected areas. By 1959, 43% of Northern Rhodesia had come under some wildlife restriction: 1) the Kafue National Park, covering 22,403 km² (8,650 mi²), was created, 2) game reserves, where no hunting was allowed except by special license, covered 26,107 km² (10,080 mi²) and 3) Controlled Hunting Areas (CHAs), requiring a license, accounted for 273,322 km² (105,530 mi²). As all over Africa, entire villages were moved in creating these protected areas, alienating rural communities who saw these protected areas as exclusion zones benefiting only the white man and colonial governments (Gibson, 1999).

“Thus the establishment of reserves and national parks did not mark a reversal in shooting policies of the past, but the final working out of the tripartite division of land use; whites, blacks and game. If reserves had been the brain child of a hunting elite, identified with the imperial right, national parks were the

inspiration of the new (urban) environmental lobbyists, the forerunners of the Greens" (MacKenzie, 1997).

Parks and game reserves were “white inventions, which elevated wildlife above humanity, which served as instruments of dispossession and subjugation” in which Africans were non-partners who were neither able to continue their traditional subsistence lifestyles in conserved areas, nor were fully co-opted into the system of Western conservation imposed on them (Carruthers, 1995). Put another way, in Africa wildlife and conservation are supplied by poor countries, with opportunity costs borne by poor people (e.g., loss of access to natural resources in agriculturally marginal areas with few livelihood alternatives), and the benefits primarily enjoyed in wealthy countries (LWAG/DFID, 2002) (e.g., international tourists, big game hunters, NGOs and researchers). In more recent times, wildlife has come to be seen as a national, regional and international public good (LWAG/DFID, 2002) with minimal accommodation for the rural people who bear the burden and costs of living with wildlife and who have given up their lands for the “greater good of mankind”! Even in 2004, the average African will never see the inside of a park since you need a vehicle to enter, as traveling on foot is usually illegal. The average African has no access to motorized transportation, and he/she cannot afford the entrance fee, let alone the lodge fees needed to spend time in the park. Even Nairobi National Park, next door to a major metropolis can be considered an outdoor “zoo” mostly visited by whites. A recent analysis of the Kruger National Park in 2003/2004 indicates that only 10% of the visitors are black (Lowry, *pers. comm.*), and compared to the rest of Sub-Saharan Africa this should be considered high. Likewise, few if any Africans can afford the costs of hunting legally in safari areas, which are even more expensive and elitist than parks, relying on low volume high paying clientele.

But Africans did/do enter these areas, clandestinely as poachers, as common criminals, often on the very lands of their ancestors, often accessing the resources

they need for survival and in carrying out the cultural rituals that keep them in contact with their ancestors, the spirit world and more and more to generate a cash income from harvesting what they consider “their” natural resources that have been confiscated from them. Most Africans are alienated from game departments and their staff, though there are innovative programs under development, which will be discussed in forthcoming Chapter 9, attempting to overcome the hurdles and gaps between governments and their constituencies in rural Africa.

3.4.2.2 Creation of game and park departments

The imposition of European laws (e.g., open and closed hunting seasons, bag limits and limitations on the taking of mostly males of the species, minimum trophy size, where hunting could take place, minimum calibers for various categories of game, remaining in one’s vehicle except within the confines of camp while in parks, Problem Animal Control (PAC) and game population control, etc.), revenue collection and the disenfranchisement and separation of Africans from their wildlife resources, required rangers, game and park wardens to administer and enforce these laws.

The early history of most African parks is one of former military officers employing what was successful in combat, waging a war in what they perceived as a battle to save the animals from the surrounding residents. Is it any wonder that rural communities have little regard for classical parks and protected areas (DeGeorges, 1992) and their paramilitary forces (Fabricius, *et al.*, 2001)? Is it any wonder that in rural Africa, someone in uniform is usually seen as the enemy?

Creation of Game Department, Northern Rhodesia (Zambia)

In 1942, the Department of Game and Tsetse Control was established. The Game Department staff supplanted the chief in rural areas. Game scouts became

responsible for local access to game. Initially, their major roles were: Problem Animal Control (PAC) to protect cropland, control of animal diseases, and preservation of game “to the benefit and enjoyment of the public”, meaning whites, in national parks. In the early 1960s, the Fauna Conservation Ordinance gave incredible powers to central government. The governor could declare game reserves, Game Management Areas (GMAs) or Controlled Hunting Areas (CHAs). The minister could authorize individuals to hunt even in contravention of promulgated hunting regulations. The director of the Game Department could prohibit or control the number, species and gender of hunted game through the licensing system. Traditional hunting methods such as pitfalls, snares, poisons, bushfires, spears and nets were outlawed. All trade in “bushmeat” was prohibited, except for local barter between Africans or legally procured game meat (Gibson, 1999).

3.4.2.3 The legal exclusion of the African hunter from his wildlife

Thus subsistence (traditional) hunting had been displaced by elite “sport hunting” with codes (MacKenzie, 1997; Adams, 2003 *In: Adams & Mulligan, 2003*) of fair chase tending to be British in origin. There was no place for the traditional hunter who had become a poacher and whose methods (bow and arrow often poisoned, snares and game pits) of procuring wildlife were considered “*unsporting, unethical and inhumane*”. “The mentality of Georgian England, when under the ‘Black Act’ poachers were transported to penal colonies or hanged was recreated in Africa. African landscapes were conceptually (and sometimes physically) cleared of peasants as unthinkingly as any village moved to enhance the picturesque landscape of an English stately home...African hunters except when reformed as game scouts” (Adams, 2003 *In: Adams & Mulligan, 2003*) or as trackers and gun bearers by professional hunters were *verboten* (forbidden).

Loss of Hunting Rights, Northern Rhodesia (Zambia)

Wildlife was valuable to Africans, and central to their livelihoods, even though forbidden by colonial laws. They continued to kill protected species, fish and hunt in game reserves, and use traditional hunting techniques. Conflict between Game Department staff and rural residents was continuous and sometimes lethal (Gibson, 1999). As an “*Open Access Resource*” belonging to the state, the rural resident’s attitude was that wildlife was either meat “*nyama*” or a crop pest, and if he did not kill it, the next man would. Rural Africans were so irritated by the colonial restrictions to access over wildlife that African nationalists were able to use this as propaganda against European rule on the Continent. Restrictions placed on hunting bred contempt for colonial administrations (Gibson, 1999; McNeill, 2002 *In:* Dovers, *et al.*, 2002). Kenneth Kaunda used the freedom by rural Africans to hunt and fish without restrictions as a rallying call for the independence movement (Marks, 1984). Unfortunately, with independence, these hunting and fishing restrictions were kept in place in Zambia (see Chapter 9, Section, 9.6.1.1, Zambia) and most of Sub-Saharan Africa.

Loss of Hunting and Territorial Rights by “San” Bushmen, Botswana

In 2003, numbering about

“100,000 in Angola, Botswana, Namibia, South Africa, Zambia, and Zimbabwe, the San present a wide spectrum of social, economic and political conditions. Some continue to hunt and gather part time, while most others work for low wages on the farms of blacks or whites in southern Africa” (Hitchcock, Biesle & Lee, 2003).

The history of the Bushmen, among the most marginalized minorities in Africa, has in the main been one of extermination, expulsion, and racial absorption. They

were hunted down and sometimes killed for such actions as stock theft; and they were incorporated into the settler production systems as cheap landless labor (Gall, 2001; Hitchcock, 2003b). Since colonial times and also under the various independent governments in the region (Botswana, Namibia, South Africa, Angola, Zambia and Zimbabwe) the hunting and gathering rights of the San were reduced step by step, dispossessing them of their most important food sources and cultural heritage (Thoma, 2002).

In Botswana, when it was declared a Protectorate in 1895 as Bechuanaland, all residents retained hunting rights on tribal land with permission of the chief. Traditional leaders and eventually colonial governments gradually removed hunting rights from local people through the imposition of hunting regulations. Since the San had no chief, they had no say in public policy. By 1935 in the Ghanzi District, San were subject to prosecution under existing wildlife legislation (Hitchcock, 2001).

Following the placement of deep boreholes, which made communal lands available year round for the grazing of Tswana herds (Cullis & Watson, 2005), the 1968 Tribal Land Act of Botswana defined land rights and use in agro-pastoral terms at the expense of the San/Basarwa hunters and gatherers. The Botswana Tribal Grazing and Land Policy (TGLP) of 1975 aggravated over-grazing and promoted the expansion of livestock into communal areas (see Chapter 6, Section 6.1.4.3, Impacts on pastoralism and range ecology from boreholes) (Smith, 1992). It was based on the assumption that communal areas were over-grazed as a result of the “tragedy of the commons” rather than from private ownership, and that many of these communal lands were unused, even though much of this belonged to Basarwa hunter gatherers. The TGLP set aside the following areas (Cullis & Watson, 2005):

- Commercial land (private individuals or syndicates);
- Communal land (based on the ‘traditional system’, but promoting ‘better management’);
- Reserved areas (unallocated land ‘set aside for the future as safeguards for the poorer members of the population’); and
- Wildlife Management Areas (WMAs) (domestic stock permitted but wildlife is the primary form of land use). Added at later date.

“Mechanisms designed to protect the poor (such as the Reserved Areas, limitations on the number of ranches owned by an individual, enforcement of stocking rates by the Land Boards, addressing the issue of dual grazing) failed to be implemented” (Cullis & Watson, 2005). Portions of the communal areas were allocated on 50 year leases as commercial ranches. The National Policy on Agricultural Development (NPAD) of 1991 continued to promote the concept of the “tragedy of the commons” and the fencing of range lands for commercial use (Cullis & Watson, 2005). The dominant Tswana groups gradually took/are taking over the lands of the Basarwa (San/Bushmen), while immigrant Herero from Namibia and Koba from Zambia also used/use their pastoral resources. Under Tswana customary law, digging a well or sinking a borehole gave/gives a person *de facto* though not *de jure* rights over-grazing and water, resulting in many Tswana elites establishing cattle posts around boreholes and hiring Basarwa as second class stock keepers, a form of indentured servitude. The Basarwa would be given 100 head of cattle to herd and although each herder was to receive five cattle from the projected annual increase in the herd of 20% (e.g., 120 cows), carnivore predation would prevent this number from being achieved. The urban elite would then require the Basarwa herdsman to pay back the five lost cattle over the next season, which in essence meant that each year the herder was deeper in debt (Smith, 1992), not dissimilar to modern foreign aid (see Chapters 11 and 12) in which the interest on the “development” loan increases each year putting

African countries into spiraling debt from which they will never escape. Smith (1992) argues that even when the Basarwa obtained livestock, their egalitarian culture of sharing and pressure from the clan to immediately slaughter the livestock for food tended to prevent them from accumulating livestock in any numbers.

Human population growth, deep boreholes in the western Kalahari and eradication of the tsetse fly around the Okavango Delta compounded the problem of invasion by livestock and outsiders in traditional hunter-gatherer/wildlife areas. The 1978 Herbage Preservation Act prevented traditional San practices such as fire to open blocked river channels, control wildlife patterns and improve wildlife feeding. This further marginalized the San/Basarwa. The government created betterment schemes concentrating people into villages called Remote Area Dwellers (RADs) Settlements of up to 750 people/settlement, creating a sedentary situation for nomadic hunter-gatherers. This resulted in a breakdown of traditional cultural and social values, the San escaping through alcoholism, an increase in teenage pregnancies and conflicts between clans (Madzwamuse & Fabricius, 2004 *In:* Fabricius, Koch, Magome & Turner, 2004). Compression of the San into relocation zones would also have placed undue pressure on and likely would have resulted in the unsustainable exploitation of natural resources around such villages. This was exacerbated by the elimination of wildlife migrations and reduction in wildlife numbers as a result of cordon veterinary fences to control foot and mouth disease needed to meet European Union (EU) requirements for beef exports (see Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana).

By the mid-1970s, anthropologists combined efforts with wildlife biologists in an attempt to guarantee subsistence-hunting rights for San foragers. As one San

explained, the Bantu depend upon cattle and agriculture, and the white man on money.

“Meat is our life. We eat kudu, duiker steenbok and birds every morning. What we really care about are big animals. These are our food and depriving us of meat is depriving us of life and the tradition that God gave us” (Hitchcock, 2001).

In 1979, the free Botswana "special game license" enabled San and other "rural area dwellers" living outside of villages to obtain wild meat for subsistence, income generation and exchange purposes, without fear of being arrested for illegal hunting. Members of Parliament, Wildlife and National Parks personnel, ecological researchers and safari hunters opposed these licenses as being obstructive to game, while ignoring such factors as the Lomé Convention's subsidized beef, which has had a major adverse impact on Botswana's wildlife populations from fencing to control foot and mouth disease, making any adverse impacts from subsistence hunting insignificant by comparison (see Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana). Slowly, special game licenses were stopped and by 1998 only issued in the Kgalagadi and Ghanzi districts, forcing more and more subsistence hunter and gatherers to become welfare cases dependent on government food relief and cash-for-work projects (Hitchcock, 2002a; 2002b; Hitchcock, *et al.*, 2003). The 1991 Agricultural Policy continued to favor pastoral lifestyles over hunter-gatherers. The 1992 Wildlife Conservation and National Parks Act further reduced San access to traditional territories. For instance, the San were not allowed to gather wild resources in the Moremi Game Reserve. Slowly, the San found themselves compressed into areas that could no longer support traditional lifestyles. Hunting, a central marker of San pride and identity, became criminalized (Madzwamuse & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004). Taylor (2000 *In:* Madzwamuse & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004) found that this did not eliminate

traditional hunting but instead drove it underground, resulting in mismanagement of the resources since the government would have lost control of being able to monitor the offtake to assure its sustainability. This is a common problem when “Open Access Resources” are created. By 2003 in Botswana, the only way that the San could get access to wildlife for subsistence purposes was to establish a Community-Based Organization (CBO) with a constitution and management board and request the Department of Wildlife and National Parks to grant the organization the rights to the wildlife in their area. The granting of wildlife rights does not imply land rights to the community-controlled hunting area. The Botswana government refuses to recognize ancestral land rights forcing San to apply like any other citizen for a piece of land. They must provide water and fencing within two years to keep the land (Hitchcock, *et al.*, 2003). In addition to the fact that most San are too poor to develop land at this rate, this makes it difficult to obtain vast tracts of land for those San who might wish to continue living traditional lifestyles, something that the Botswana government apparently wishes to discourage. Jones (1999) also raises concern over marginalization of San from the loss of special licenses and the creation of Community Management Areas (CMAs) with hunting quotas. Since many Community Management Areas (CMAs) (see Chapter 9, Section 9.6.3.4, Botswana Community Trust Program) and the San living in CMAs are dominated by other ethnic groups, San may still fail to obtain legal traditional hunting rights.

Today, many if not most San of Botswana live in small settlements, earning their living through a combination of foraging, agriculture, livestock raising, small-scale industries (e.g. handicraft sales), and wage labor. A substantial portion of the San live below the Poverty Datum Line (PDL) of less than US\$ 1/day and face difficulties ranging from access to land, social services, employment, and income-generating opportunities to social marginalization (Hitchcock & Biesle, 2002). A major problem facing hunters-gatherers in Africa is that colonial and post-colonial governments passed conservation laws restricting the rights of local

people to hunt (Marks, 1984, Anderson & Grove, 1987; Neumann, 1998; Gibson, 1999; Prins, Grootenhuis & Dolan, 2000 all *In:* Hitchcock, 2001) in addition to declaring sizable portions of African countries as national parks and game reserves which were off-limits to local people. The San and other indigenous people lost over 50,000 km² (Hitchcock, 2001) to parks and reserves in Southern Africa. Over the last decades, there have been some advances such as the ≠Khomani San gaining co-management rights in the Kalahari Gemsbok Park as the result of filing a formal claim under the South African Restitution of Land Act, which was settled out of court (Hitchcock, 2001).

Loss of Hunting Rights in Namibia (Southwest Africa)

In Namibia, the San still retain some but limited hunting rights on what little land they have left, which has been turned into conservancies. Leaving behind a colonial history of more than 150 years, Namibia became a sovereign state in March 1990. In the wake of colonialism, *Apartheid* and a long liberation war, socio-economic conditions for Namibians remain starkly unequal. There is a white, prosperous Namibia and a black, impoverished Namibia. The disparity began with the arrival of European settlers. Namibia's living natural resources, especially its wildlife, were an important source of wealth for the indigenous people. The colonial regimes brought with them the concept of "King's Game", meaning that wildlife once belonging to local people became the property of the State. Under colonial rule, the legal use of Namibia's wildlife was the exclusive privilege of white colonialists. For black communal land inhabitants, wildlife was no longer seen as a resource. Under the Apartheid system, racially-motivated hunting laws and government policies concerning conservation of wildlife and other natural resources made national parks basically off-limits to black Namibians, effectively denying them access to the country's resources and economic opportunities. People living in proclaimed game reserves were made potential criminals if they killed wild game or

collected veld plants for food. Government representatives enforced white ownership laws and, in the process, created hostile relationships with local black residents (USAID, 1992).

Loss of Hunting Rights in South Africa

Surprisingly, the South African Republic's Ordinance 28 of October 1902 treated landowners, both white and black equally, with regard to hunting privileges – for the first time giving Transvaal landowners hunting rights. This implies that non-landowners lost the right to hunt. Land-owning companies based in Johannesburg heavily represented through the Transvaal Game Protection Association (eventually to become the Wildlife Protection Society of South Africa) and the Transvaal Land Owner's Association attacked both subsistence and commercial hunting. As discussed, laws disallowing trapping, hunting with dogs, ownership of firearms, etc. in South Africa had less to do with a concern over the reduction in wildlife as the need to prevent subsistence hunting from possibly creating African independence from the labor market on white-owned farms and mines. The professional Boer hunters were perceived by the landed gentry and urban elite as poor white trash, with legislation being passed to stop commercial mining of this resource in favor of the only acceptable motivation of "sport hunting" by these elite. Thus poor landless blacks and Afrikaners lost their rights to live from wildlife both at subsistence and commercial levels. Meanwhile, these "sportsmen" helped pass legislation to eliminate what was then considered "vermin", including lion, leopard, wild dog, cheetah, hyena, jackal, birds of prey, crocodile and many other reptiles because they: 1) were "evil" endangering human life or livestock, and/or 2) fed on the sport hunters' prey – antelope species which were seen as rapidly dwindling from over-hunting by these predators. Along with vermin, Blacks and poor white trash, needed to be eliminated as a threat to game and sport hunting. In 1926, when Kruger was

declared a park, the killing of lion in the park as vermin was stopped, this species eventually becoming a major tourist attraction (Carruthers, 1995).

In 21st century Sub-Saharan Africa, citizens of Botswana can easily obtain affordable hunting licenses if they are part of the salaried economy, hunting in theory being a constitutional right. While sustainable use is written into South Africa's constitution, the historical past dissuaded the majority from hunting; the cost of hunting is out of reach of the majority and the new gun legislation (SAP, 2000) as being implemented will likely make owning a firearm for hunting nigh impossible for the majority. In other countries, where traditional hunting might be legal, the average citizen is unaware of the law, the cost of a license, though low by Western standards, is often high for people living a subsistence economy. The idea of a hunting license is often resented by people as an imposed requirement by an unrepresentative government and/or the logistical difficulty of obtaining a license (e.g., the capital or regional town) force many to hunt outside of the law. Unfortunately, in most of Africa, though unenforceable, existing laws have changed little since the colonial days, still turning traditional hunters into poachers. Forcing traditional hunters to poach combined with increasing urban demand for "illegal and unregulated" bushmeat makes centralized government management of wildlife resources next to impossible. Legalizing access to and regulating the offtake of wildlife by rural Africans will be critical to the survival of wildlife and its habitat in the 21st century.

3.5 DEVELOPMENT OF HUNTING ETHICS IN AFRICA

The ideals of ethical hunting were only put forth and even considered once wildlife had served its purpose in exploration and the colonial takeover of the African continent had taken place, allowing hunting to play a more ritualistic than utilitarian role in society. As seen below, the same can be said of America.

These ideals included not shooting at a water hole, getting close enough to judge age, sex and quality of trophy, no use of dogs, no shooting of female and young, giving the animal a ‘sporting chance’ to escape, following up and giving the coup de grace to a wounded animal and not shooting from a motorized vehicle (MacKenzie, 1987 *In: MacKenzie, 1997*).

MacKenzie (1997) goes on to say,

“Moreover the true sportsman was a natural historian and a scientist. Killing was in a sense legitimated by his understanding of the quarry, its environment and its anatomy, and his knowledge of firearms and ballistics added an extra scientific dimension. The hunter had become an exclusive club, its rules defined by Western technology and science. The code, though transgressed by many white hunters (still the case with canned lion, spotlighting and shooting from vehicles by so-called sportsmen), from Theodore Roosevelt downwards, served to exclude Africans and Indians. It underpinned game legislation, which attempted to eliminate ‘cruel’ African and Indian (from India) practices. By these means, the club’s rules became national laws”.

However, in many cultures (e.g., German, most Africans) and to many hunters the words “sport hunting” and “sporting” are frowned upon. Yes, like in any sport one must be fit to walk the savannas and forests and climb the mountains pitting one’s body and mind against the challenges of nature; the elements, danger, and for many the spiritual – both good and evil. However, hunting is not a competition. Hunting is a way of life, a reason for being, an experience, but never competition.

Towards the end of the 20th century, the development of “competitive hunting” promoted by international sport hunting clubs that give awards for large trophies or for obtaining a number of animals from a particular category (e.g., Big Five, Spiral-Horned Antelope, etc.) spawned a new breed of hunter, the “collector” as

opposed to the “sport hunter”. The Collector tends to be wealthy, often growing up in a non-hunting environment, or “hunting” on the New York Stock Exchange. He is not steeped in the traditions of “the hunt”. The “collector” sees these awards as another way of showing off his “alpha-male” (not many serious collectors among women, though a few exist) success oriented personality. He places tremendous pressure on his professional hunter, to obtain his trophy at all costs. Ethics in the hunting sense means nothing to the collector, not being part of his upbringing nor of his vocabulary.

The “sport hunter”, and he still exists, hopefully still among the majority, looks for the experience of the hunt and the collection of the best trophy he can obtain. However, he is willing to settle for a representative trophy as a souvenir of that experience if obtained under “fair chase conditions”, that is under conditions in which the game has an acceptable chance of escape as determined by the collective hunting fraternity. Both the “collector” and “sport hunter” still tend to be WASP (White Anglo-Saxon Protestant) reflecting the elitism of their European ancestry, though many are *nouveau riche* as opposed to the old European aristocratic families of a generation ago that dominated the hunting scene. Safaris of 1-2 months have turned into 7-14 day safaris, as a need to get back to the board room in modern society places that much more pressure on the safari operator/professional hunter to ignore ethics. Many hunters are happy to enter into their hunting block, having as little contact as possible with Africans. Ecotourists are not believed to be much different, being shuttled upon arrival at the international airport to luxury lodges hidden inside parks where only wildlife, not people, is to be seen.

Interestingly enough, and for comparison sake, the African Advisory Board (AAB) (2000b), an informal body of stakeholders comprising governments, rural communities, professional and sport hunters, conservation NGOs and

academics/researchers, established in Africa in the mid-1990s, becoming defunct by 2002, developed a similar code to what is discussed above in MacKenzie (1987 *In: MacKenzie, 1997*).

One of the big differences between “British hunting codes” from colonial times and this code is that it recognizes the rights of rural Africans to use and sustainably manage their resources, and allows for modification based on “traditional/customary” hunting practices (e.g., hunting with dogs, crossbows, pitfalls, snares, etc.) if negotiated with the particular stakeholders in a given country or region of a country involved in conservation. Other than that, it clearly reflects the European, especially British origins of the idea of “sport hunting”, an alien concept to Africans other than those who have received a Western education. This code caused a major brouhaha/upheaval among international bow hunters since this code was developed by rifle hunters.

CODE OF ETHICAL SPORT HUNTING CONDUCT FOR AFRICA

- “Hunting to take place on the principles of fair chase, as defined.
- Abide by relevant laws, other legal requirements and recognized codes of conduct.
- Enhance by action, the survival of wildlife populations, protection of biodiversity and the promotion of sustainable utilization.
- Ensure humane practices in the utilization of wildlife.
- Use of correct hunting methods and equipment.
- Engage at all times in fair and honest practices.
- Educate others to the benefits of sustainable use, conservation, correct procedures and the ethics of hunting.
- Recognition of indigenous rural communities needs’ relating to sustainable natural resource utilization.

Every sport hunter shall pursue an animal only by engaging in fair chase of the quarry. Fair chase is defined as pursuit of a free ranging animal or enclosed ranging animal possessed of the natural behavioral inclination to escape from the hunter and be fully free to do so. Said animal is to be hunted without artificial light source, or motorized mode of transport and in an area that does not by its nature concentrate animals for a specific purpose or at a specific time, such as at a waterhole, salt lick or feeding station. No ethical hunter while sport hunting shall take female animals with dependent young. A sport-hunted animal should exist as a naturally interacting individual of a wild sustainable population, located in an area that meets both spatial and temporal requirements of the population of which that individual is a member. Sport hunted animals should, wherever possible, be sustained within an ecologically functional system. The above definition may be modified by the regional hunting associations based upon legal, customary and necessary circumstances that may be unique to each country or area. Accepted and Recommended by the African Advisory Board, 1999” (African Advisory Board, 2000b). Note: This is a minor modification and improvement of a code first developed in November 27, 1997 by the African Advisory Board.³² Prepared by principal author.

³² Key safari operators/professional hunters signing off on the 1997 document include Tony Dyer of the old East African Professional Hunters Association; Gilfrid Powys of Kisima Ranch, Kenya; Bassie Maartens and Volker Grellmann, pioneers of trophy hunting in Namibia – at the time Bassie was also Chairman of the Professional Hunters Association of South Africa (PHASA); Rolf Rohwer, one of the pioneers of hunting in Zambia and at the time hunting in Tanzania; Johan Calitz, one of the major operators in Botswana; Charl Grobbelaar, a professional hunter and chairman of the amateur sport hunting association – Zimbabwe Hunters Association; well known French professional hunter Richard Rouget; well known Southern African professional hunter,

In Southern Africa, many overseas “*sporting*” bow hunters shoot game from blinds placed at waterholes, salt licks, and feeding stations on private fenced game ranches,³³ even placing food at waterholes as an attraction. All these practices are unacceptable to rifle hunters, and make bow hunting less of a challenge instead of more of a challenge that should be the reason for hunting with primitive weapons. The problem lies in the fact that hunting is becoming a business and a means of earning a living that ultimately results in compromising the ideals of what is ethical. Without such aids, a bow hunter would be lucky to obtain one to two animals while walking and stalking over a seven to ten day period. The landowner often makes much of his income on numbers of game harvested, while the reputation of the safari operator/professional hunters depends largely on word-of-mouth praise from the returning “successful” sport hunter to his friends in the U.S. and Europe. Given the expense of getting to Africa and the cost once there (e.g., US\$ 350/dollars/day paid to safari operator), few hunters would return happy with one to two trophies. Thus, ethics is regularly compromised for monetary reasons, creating what some call the “wackem and stackem” mentality.

The afore-mentioned code implicitly does not accept “canned lion hunting” as sporting, that is the raising of lions in pens and then releasing them into fenced

John Oosthuizen; Dieter Ochsenbein, well known sport hunter and head of the Taxidermist Association of South Africa and eventually PHASA; Gerhard Damm, well known sport hunter and first/last president of the Safari Club International (SCI) African Chapter; Humphery Nzimah of the Malawian government; Lance Norris and Skip Donau, today both past SCI international presidents; Rudy Rosen at the time Executive Director of SCI; John Finch, SCI staff member and Andre DeGeorges, at the time manager of the SCI Africa Office. Professor Brian Reilly, Department of Nature Conservation, Tshwane University of Technology, South Africa, contributed significantly to the final version seen above.

³³ A “*game ranch*” implies an area large enough to produce a diversity of free ranging and breeding populations of wildlife, whose annual population growth can be harvested in a variety of ways from trophies, biltong (dried meat), venison, live capture and sale. Many game ranches in South Africa tend to be too small to form economically viable units, being weekend retreats for the rich from Pretoria/Johannesburg. Uneconomically viable game ranches are another reason for the above-noted unethical practices (e.g., put and take), when they are used to earn a livelihood. A “*game farm*” tends to be a smaller area in which high value species tend to be captive bred in a mono-culture system such as ostrich, crocodile, sable, roan, and most recently lion. Often there is a fine line between the two, as lion may be bred in camps and then released on the same ranch into a larger but fenced area, or sold and released into a larger area where they are hunted.

areas just before the hunt, sometimes with the use of drugs to subdue the lion on bait. It does not consider “put and take” hunting as sporting where game is bought at an auction like livestock and shortly thereafter dumped on a ranch and shot by unsuspecting clients thinking they are hunting fair chase game. These are all practices acceptable to “collectors” who don’t care about “fair chase” or in how they obtained their trophy. In many cases, these practices are legal. “Canned lion” do not meet the above ethics requirements of “free ranging animal or enclosed ranging animal possessed of the natural behavioral inclination to escape from the hunter and be fully free to do so”. Nor does it “exist as a naturally interacting individual of a wild sustainable population, located in an area that meets both spatial and temporal requirements of the population of which that individual is a member”. Canned lion are kept in small camps and fed domestic animal carcasses and thus do not meet the criteria of “sustained within an ecologically functional system”. It is likely that “canned lion” hunting may be more dangerous than hunting wild lion, but, there is no “fair chase” that is no “natural behavioral inclination to escape from the hunter and be fully free to do so” as the tendency will be for the lion upon seeing a human to come for him, expecting to be fed and/or to feed on man that the lion no longer fears. Additionally, raising “canned lion” does little to protect wild lion since captive bred lion have never been successfully released into the wild. The future of wild lion seems to be linked to maintaining enough open space from the ever-growing encroachment by man, while at the same time convincing rural Africans that lion and other wildlife have a value in modern times (see Chapter 9 that discusses Community-Based Natural Resource Management [CBNRM]). The majority of sport and professional hunters who developed this code believe that under such conditions (e.g., canned/put and take) trophies should not be allowed into the record books of international sport hunting organizations such as Safari Club International (SCI)³⁴ and Rowland Ward.³⁵

³⁴ Safari Club International, 4800 West Gates Pass Road, Tucson, Arizona 85745-9490

Once again, the need of the landowner to earn a living off otherwise valueless veld is at the base of “canned hunting”. If tomorrow, one was dumped onto a South African ranch and given the opportunity of raising cows worth a few hundred dollars each or lions, prolific breeders that can bring in US\$ 20,000 or more/hunt, the choice would be rather easy, especially with a wife and children to support. There is a market out there consisting of “collectors” who don’t care about fair chase ethics and who just want a stuffed lion in their living room. It is not only lion that are “canned”. Sable, roan, white rhino and even kudu (e.g., 60 inchers) can be bought and dumped on a farm where an overseas hunter may knowingly or unknowingly “kill” such an animal.

The hunting fraternity has determined that this is not hunting but “*killing*”. Lion hunted in Namibia and South Africa were taken out of SCI’s record book in 1997 (SCI, 1997). Lion raised in camps are neither free roaming nor free breeding. Since there have also been fair chase lion taken in these countries, with proof, one can reapply for inclusion of a fair chase lion trophy in the record book.³⁶ The question that must then be asked, is no longer should “canned lion” be considered “*hunting*”, which it is not. Greater society will likely have to determine whether raising and providing “canned lion” to be “killed” is acceptable or not. If it is not, then ostrich and crocodile farming might also be condemned, and then when does it end?

³⁶ SCI has put lion entries from Namibia and South Africa back into its latest record book (2006), but separated them out from the rest of Africa (Venter, *pers comm.*), likely from pressure by “collectors”. Linder Venter, Manager/Consultant, SCI South Africa Office, Centurion, South Africa.

Another problem is that many game ranches are too small to be economically self-sufficient. The minimum size varies depending on *veld* type, but on average, those ranches below 2,500 ha are economically unviable since game populations are not large enough to produce an annual sustainable supply of huntable trophy quality game. In attempts to maximize economic returns, small ranches stock up with game from auctions, including non-indigenous species that provides an increased diversity of game to the overseas client and practice “canned hunting”. Prior to the beginning of each season trophy animals are often bought at a game auction, dumped on the farm and then shot off (put and take) by overseas hunters, this process being renewed each year.

Landowners/safari operators and hunters have yet to sit down and reach consensus on the way forward over these issues, for the most part remaining divided. Even among bow and rifle hunters, there is a need for dialogue. By being divided and not speaking with one voice, the hunting community becomes vulnerable to the anti-hunting animal rights movement who would like to see this important Sub-Saharan Africa industry shut down.

Recognizing traditional hunting rights, beginning in 2001/2002 in KwaZulu Natal, South Africa, there has been some opening up to allow controlled hunting of antelope with dogs and clubs by traditional Zulu Hunters.

3.6 THE END OF COLONIALISM AND THE ACCELERATION IN PHYSICAL SEPARATION OF AFRICANS FROM THEIR RESOURCES

Towards the end of colonialism, when European colonizers began to realize that uncontrolled harvesting of game, land clearing, and a doubling/tripling of humans and livestock in the first half of the 20th Century had virtually eliminated “Wild

Africa". Accelerated efforts were made to create parks, game reserves and hunting blocks in order to preserve Africa's mega-fauna.

The final years of colonial rule in East Africa witnessed the extension of conservation policies. The East African Wildlife Association was founded in 1956 (MacKenzie, 1997) to save Africa from the Africans and to encourage the creation of more parks and game reserves, separating "*people and wild non-human nature*" (Adams, 2003 *In:* Adams & Mulligan, 2003). Leakey and Lewin (1996) claim the East African Wildlife Society was founded in 1958 by Louis Leakey. There was no need for "Problem Animal Control (PAC)" but rather "Problem People Control".

Throughout Africa, the New World and Australia, European settlers brought their brand of conservation in which parks and game reserves became large zoos, "Sherwood Forests" for the pleasure of the political elite, but to the disadvantage of the very people whose lives had been integrally linked to wildlife. The lives of indigenous people would forever change as a result of the "surgical" removal of these cultures from their ancestral grounds. The creation of parks and protected areas wiped out entire civilizations relegating them to the margins of mankind.

The American model of "fortress conservation" was implemented wherever the opportunity presented itself. In Uganda, "the clearing of human settlements from areas threatened by sleeping sickness (carried by tsetse flies and therefore common in wildlife areas) presented an opportunity to create protected areas" (Barrow, Gichohi & Infield, 2000). This concept was strengthened by the concept of the "tragedy of the commons", purporting that the common ownership of resources cannot succeed (Harden, 1968 *In:* Boggs, 2000 *In:* Fabricius, 2004 *In:* Fabricius, *et al.*, 2004).³⁷ What this premise ignored, as discussed under Chapter

³⁷ Note in other references Harden is spelled as Hardin

2, is that indigenous peoples in Sub-Saharan Africa and for that matter all over the world had management systems in place that worked and are working, and that were and are (see Chapter 11) being ignored in favor of centralized management systems. Centralized management systems have been the real cause for the “tragedy of the commons” by destroying “Common Property Resources” managed by local communities in favor of creating “Open Access Resources” (see Section 3.7, CREATION OF OPEN ACCESS RESOURCES).

Wildlife was allowed to expand into large areas abandoned by people because of forced removals, which compressed people into small, often unsustainable areas, compounded by the population explosion of the 20th century. This has resulted in over-grazing, desertification, the gross impoverishment and often genocide of rural Africans. Thus, the British colonial government continued the ecological transformation that had begun in the 1890s in East and Southern Africa (Kjekshus, 1977) which favored wildlife over people, and in the creation of Anglo-Norman exclusion zones dating back to the idea of royal forests and game belonging to the crown. Examples include (Kjekshus, 1977):

- The forced removal of 500 people from the Gombe Stream Chimpanzee Sanctuary, just north of Kigoma on the shores of Lake Tanganyika.
- The Mbulu Game Reserve, Tanganyika, containing 10,000 people, their settlements and 1000s of acres of grazing land.
- The Katawi and Sabi River Game Reserves, Tanganyika where the removal of people was required.
- The Budonga Game Reserve by Lake Albert, Uganda, from which people were eventually removed to protect them from tsetse fly and to encourage the proliferation of wildlife over the 12,950 km² (5,000 mi.²) reserve (MacKenzie, 1997).

- The Serengeti Game Reserve, in which the Maasai lost 83% of their former land area.
- The Selous Game Reserve (SGR) from which 40,000 people were moved out.

A medical missionary wrote to the governor of Nyasaland that “ ‘the victims of trypanosomiasis are martyrs to the foolish policy of game protection’ ” (MacKenzie, 1997). Another missionary argued that when he had first entered Nyasaland, Africans had kept the vicinity of their villages clear by destroying game. They were prevented from doing so by the colonial authorities and game laws aimed at allowing hunting only by the colonial settler elite. The realization was only dawning of “ ‘the enormity of what we have done’ ” (MacKenzie, 1997). As in East Africa, reserves had been established in populous districts and ‘the balance of nature had been upset.’ Missionaries began proposing that Africans should be permitted to take up arms and that ‘their ancient hunting rights should be restored’ (MacKenzie, 1997). Of course, this was ignored, along with traditional common property management at the local level, as described in the last chapter.

3.6.1 Separation of Maasai from Ngorongoro Crater

Ngorongoro Crater was a prime Maasai grazing area. When ordered out of the crater in the early 1950s, the Maasai responded as follows, “We told them you better shoot us together with the cows”. On April 21, 1958, twelve Maasai elders signed an agreement to abandon the western Serengeti without knowing what this agreement implied. By 1974, due to the tourism potential and concern over limited water supplies, the Maasai were forced out of the Ngorongoro Crater, though with permits they could enter temporarily with their cattle to procure salt and water. It is now easier for the 150,000 annual tourists with their tremendous

consumption of water to enter the crater than for a Maasai and his cows (Bonner, 1993). Colonial policies continued after independence, driven by Western donor-backed international conservation organizations.

Resident pastoralists in the Ngorongoro Conservation Area (NCA) that includes the crater and the surrounding 8,300 km² (Maliti, 2003) “are assured of rights to habitation, grazing, and access to water and salt. However, the actual accrual of benefits resulting from tourism has been less clear, and has caused an increasing amount of conflict between the resident peoples and the Ngorongoro Conservation Area Authority (NCAA)” (Barrow, *et al.*, 2000).

In the early 1990s, the closest secondary school for the Maasai living along the edge of the crater was a two-day walk. Little or no employment came to the Maasai from tourism, and no money obtained from ecotourism went to the Maasai living in the greater conservation area for development. As Western educated wildlife biologist and author Tepilit Ole Saitoti said, “We are beginning to think that the whites care more about the future of wildlife than the Maasai. We are thinking that maybe we need to eliminate the wildlife if we are to survive” (Saitoti, *pers. comm.*), and this being said by someone with a masters degree in natural resource management and whose ethnic group had co-habited with wildlife for centuries until the coming of the white man. On the other hand, he went on to say, “We are not stupid. Although cattle will always be part of our lives, let us see significant benefits from wildlife and we will destock a percentage of our livestock to favor wildlife” (Saitoti, *pers. comm.*).

The development of a NCA management plan (NCAA, 1995 *In:* Barrow, *et al.*, 2000) is said to be more participatory.

“Continued participation in planning, and agreed rights and responsibilities for all the parties, will be key to the future success of the NCA as a multiple use conservation area. Of particular

concern is how the NCA will handle such issues as integrating livestock and wildlife migration routes, providing support for transhumant pastoral production, land and water rights, supporting community resource tenure arrangements, food security and the sharing of benefits from the NCA. These will be key issues to integrate if the NCA is to remain one of the wonders of the world" (Barrow, *et al.*, 2000).

3.6.2 Forced Removal, Kruger National Park, South Africa

The 19,000 km² Kruger National Park was first established as the Sabi Game Reserve lying between the Sabi and Crocodile Rivers in 1898 (expanding north to the Olifants River in 1903, and eventually adding the Singwitsi Game Reserve) in order to build up game as a result of over-hunting. In 1902 Sabi was a shadow of what it is today with regard to wildlife populations. It had no black rhino, elephant, eland, hartebeest or ostrich, while there were only five giraffe, eight buffalo, 12 sable antelopes, two roan antelopes, five tsessebe, 40 blue wildebeest, 100 waterbuck, 35 kudus, and numerous impalas, steenbok and duikers. The Sabi and Shingwedzi Game Reserves became the Kruger National Park as a result of the 1926 National Parks Act. Interestingly enough, initially scientists, mainly veterinarians, were against the park seeing it as a reservoir for wildlife diseases such as rinderpest, sleeping sickness and foot and mouth that could be transmitted to livestock (Carruthers, 1995).

Kruger's third and longest reigning (1902-1946) warden James Stevenson-Hamilton had a major influence in South Africa's thinking towards the "*preservation*" philosophy of parks and game reserves. He distinguished between a preserve in which hunting was allowed, and sanctuary/state game reserves and national parks in which there would be no hunting. The sanctuary/reserve/park would be managed under the modern concept of non-interventionist "natural regulation" (Carruthers, 1995) following the

“precautionary principle” supported by the Western animal rights movement in the 21st century that allows nature to take its course.

This is as opposed to the eventual pro-active “adaptive management” (including culling) approach of parks in South Africa, which marked the applied scientific management that followed Stevenson-Hamilton’s forced retirement in 1946 at about the age of 80 with the takeover of national parks by highly motivated Afrikaner scientists, which proved to be a form of affirmative action (Carruthers, 1995) (see Chapter 9 for further discussion on the precautionary versus adaptive management principles). The imperialist sport hunter’s “pleasure in random bloodshed” was replaced by “sanitized and efficient killing” by means of darts shot from helicopters (Carruthers, 1995), as parks became the exclusive “hunting grounds” of privileged veterinarians, researchers, and rangers. Had anything really changed or had hunting arrived at the next level of elitism, a new “privileged class” that enjoys, even today, these exclusive rights and the “chase” as much as those elites who had preceded them?

The creation of the Kruger Park, similar to American parks, was based on colonial whites’ acceptance that game viewing and wildlife research were viable land uses (Carruthers, 1995; Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*). Stevenson-Hamilton organized the management of Kruger along para-military principles, breaking the park into sectors controlled by rangers and their African teams to control African residents in their sectors and to arrest poachers (Carruthers, 1995).

In the late 1940s, the Kruger Park became a symbol of Afrikaner nationalism and a playground for white researchers and tourists – the nakedness of *Apartheid* clothed in the fig leaf of conservation (Carruthers, 1995; Carruthers, 1997 *In: Griffiths & Robin, 1997*). In 1900, only 10% of the Afrikaners, descendants of the

Voortrekkers, lived in urban centers. By 1926, 41% lived in urban centers forced out of the rural areas by the capitalization and commercialization of farming to live in slums as mine, rail and factory workers (Swart, 2003 *In:* Beinart & McGregor, 2003). With the beginning of Afrikaner nationalism, the Kruger Park became a major symbol, for the poor, working, urbanized Afrikaner family to escape industrial pollution and materialism, and for the youth to hark back to simpler times when their forefathers, as sons of the soil led a carefree, pastoral life with the veld as their classroom (Bunn, 2003 *In:* Beinart & McGregor, 2003), hunting and living off the land, close to God. The Kruger Park eventually served as a buffer zone against so-called terrorists from Mozambique (Magome & Murombedzi, 2003 *In:* Adams & Mulligan, 2003) during the activities of the liberation movements in the 1980s.

In 1902, at least 3,000 residents were forcibly removed from what was to become the Kruger National Park (Carruthers, 1997 *In:* Griffiths & Robin, 1997). The Kruger Park headquarters and most famous rest camp at “Skukuza” is the nickname given to Stevenson-Hamilton by the evicted Tsonga tribesmen, meaning “he who sweeps clean”. This is a name still given to the entire park by many South Africans (Fabricius, *et al.*, 2001). Stevenson-Hamilton (1937), speaking of the 1902 era, states “the Reserve has been cleared of the natives, who had been moved north of the Sabi and south of the Crocodile Rivers”. However, not all blacks were excluded. Carruthers (1995) describes how after 1905 many scattered residents were seen as an asset and allowed to remain within the park as a source of three-months/year compulsory labor and rent. At that time, there were still 3,000 residents in the Sabi/Singwitsi Game Reserves of which 400 were dues-paying tenants. Poaching was minimal except during droughts, where wildlife served as a food safety-net. The threat of losing their land and becoming subservient laborers on white farms appeared to be the major incentive in controlling poaching as opposed to the threat of forced labor, fines or jail time.

Most poaching came from people residing outside the reserve/park, blacks in South Africa south of the Crocodile River or Mozambicans who could legally own firearms. In 1915, out of 520 arrests in the Sabi/Singwitsi Game Reserves (eventual Kruger Park) only 27 were for poaching; in 1916, this amounted to 91 out of 763 convictions and 37 out of 408 in 1918. Even so, the general view of whites was that Africans living within or near parks could not be trusted to take care of wildlife (Carruthers, 1995).

By 1931, there was mounting aggression against Africans and their cattle living within the park and competing with wildlife. On the other hand, the semi-feudal system of a park under white control managing both the African and wildlife appealed to many. The western border remained unfenced in the 1940s against the will of bordering Afrikaner farmers, though this arrangement was favored by the English speakers. The National Parks Board of Trustees argued that the natives were competing against neither the white farmer nor wildlife, growing just enough food to survive and keeping enough cattle as a bride price; they were “raw natives living under the tribal system”, a picturesque remnant of an older system. In 1939, foot and mouth disease required the elimination of all cattle (1,200) in the park and another 14,000 outside in the Crocodile River District. Africans resided in the park until the 1960s, thereby “protecting the Africans from the corrupt forces of modernization” (Bunn, 2003 *In:* Beinart & McGregor, 2003).

While blacks were said to be legally restricted from entering Kruger (Magome & Murombedzi, 2003 *In:* Adams & Mulligan, 2003), Carruthers (1995) depicts a slightly different but possibly more humiliating picture in which blacks were allowed into Kruger Park on an “unequal basis” in terms of accommodation and recreational facilities. In 1932, a rudimentary tented camp called Balule existed for Africans (Carruthers, 1995). It is suspected that the eventual cost of entry, the necessity of having a vehicle and the primitiveness of facilities offered blacks as

opposed to whites (shops, petrol stations, rondavels, toilets, running water, etc.) acted as a social barrier of exclusion every bit as effective as making it illegal for them to enter. It sent black South Africans the appropriate message, “You savage poachers are not welcomed here! Parks and game reserves are for white people who appreciate the aesthetics of nature”!

Forced removal on a large scale was begun by the early 1950s when South African reserves and parks became exclusion zones. They tended to be fenced to keep people out and wildlife in, requiring pro-active management to control what had become contained game populations surrounded by a hard-edged sea of poverty. In 1969 under Apartheid South Africa, 1,500 members of the Makuleke Community were forcibly removed to expand the Kruger Park northward into “Crook’s Corner” (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*) (see Chapter 9, Section 9.6.3.7, Makuleke Contractual Park, South Africa), once used by elephant poachers to slip back and forth across Zimbabwe, Mozambique and South Africa as a means of avoiding authorities. They were dumped 100 km away, becoming subjugated by a powerful ethnic group, the Mhinga, which resulted in the destruction of their traditional social structures.

The relationship of Kruger’s South African National Parks (SANparks) staff and local communities was adversarial, one of classic “fences and fines” with SANParks officials playing the role of policemen, and locals who entered the park being seen as poachers (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*).

A 1995 land claim restored the “Crook’s Corner”, consisting of 250 km² in the extreme north of the Park to the dispossessed Makuleke Community with the understanding that it be reserved purely for conservation with no residences, mining or agriculture within the boundaries of this property. Though part of

Kruger, the section was de-proclaimed from a national to a “contract national park” for 50 years, allowing the Makuleke to award safari hunting and tourism lodge contracts while under co-management with SANParks. Contract national parks were originally conceived under *Apartheid* South Africa to co-opt powerful white landowners into mutually beneficial agreements, which expanded the park estate without having to purchase additional land. It was not meant for black communities, who could have their land confiscated with no legal recourse; this changed with the end of *Apartheid* in 1994. The co-management agreement is a result of unequal negotiation between relatively disadvantaged community representatives and sophisticated and advantaged officials of SANParks; “chefs with quite different menus, and different powers to cook them”. Co-management has seldom succeeded elsewhere in South Africa (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*). It might be considered a form of “indirect rule”.

SANParks still controls access to wildlife, a major source of conflict with the Makuleke, who preferred consumptive use (e.g., traditional hunting and safari hunting) and, one could argue, a form of neo-colonialism. Youth from the area have been sent off for formal training in tourism hospitality and conservation management, while the sophisticated “white” NGO “Friends of the Makuleke” provides the community with coaching and advice. In 2000 and 2001 respectively, US\$ 80,000 (from two elephant and two buffalo) and US\$ 130,000 were made from a limited offtake of trophy elephant and buffalo for community projects (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*). Safari hunting was stopped in 2004, as the Makuleke have opted for ecotourism lodge development under a contract with Wilderness Safaris (see Chapter 9, Section 9.6.3.7, Makuleke Contractual Park, South Africa). Wilderness Safaris is said to have links to the Vice President of Botswana, Ian Khama, and is openly anti-hunting (see Chapter 9, Section 9.6.3.4, Botswana Community Trust Program).

3.6.3 Forced Removal, Pilane Clan, Pilanesberg National Park,³⁸ South Africa

Creation of the Pilanesberg National Park was the means of legitimizing a “nation”, one of Apartheid’s “independent states”, easing it into international respectability. After having won back their land, originally confiscated by white farmers, the creation of Pilanesberg National Park involved the forced removal of black farmers for the second time. Its creation was opposed by the Pilane clan. This park did not conserve a natural area, but refurbished abused (by both whites and blacks) grazing land, fenced it and restocked it with game. The establishment of the Sun City Casino Resort next door helped Pilanesberg become an international tourist destination. Community benefits included meat from culling and a percentage of the revenue from hunting and photographic safaris. In modern environmental policy circles, national parks are losing ground. National parks and other protected areas were established for colonial elites and today primarily wealthy overseas tourists. This fortress approach has alienated rural people, disenfranchised them, ignored traditional controls over access to these resources, and is resulting in parks and protected areas becoming islands of biodiversity under siege by a wave of humanity (Carruthers, 1997 *In: Griffiths & Robin, 1997*). An interview of peripheral villages around the Pilanesberg Park in 2003 by an official of the Northwest Parks and Tourism Board provides insight into the viewpoint typical of the majority of rural Africans towards parks and protected areas: the Pilanesberg Park is perceived as being for foreigners, rich people and government. The people would like the park to provide them with jobs and scholarships to higher education (Mathebula, *pers. comm.*).

³⁸ Pilanesberg was a national park under the old Bophuthatswana homeland. Today it is a provincial game reserve under the Northwest Parks and Tourism Board used for tourism, hunting and live game sales.

3.7 CREATION OF OPEN ACCESS RESOURCES

The imposition of Western legal systems declared that wildlife belonged to no one and that killing game was not a real crime unlike the theft of livestock, which was private property (Carruthers, 1995). The centralization of control over natural resources, including wildlife, fish and forests, resulted in “common property” managed resources (Chapter 2), becoming unmanageable “Open Access Resources”. Traditional extensive management systems began disappearing. In essence, wildlife belonged to everyone but was the responsibility of no one but the state, which at the beginning had other priorities than worrying about wildlife. When it did, it was generally too under-staffed and under-financed to control an increasingly disenfranchised and alienated majority, rural black communities. This continues in the 21st century under the independent states of Sub-Saharan Africa, which for the most part are still living with the colonial legacy and laws towards wildlife and other natural resources.

The artificial separation of humans and natural resources and anti-poaching policies against the masses in Sub-Saharan Africa were resisted and doomed to failure as they were politically untenable, resulting in national parks (also game reserves and hunting blocks) that were/are constantly compromised by the indigenous people. Subsistence poaching became a form of protest against unfair and unequal wildlife policies that had no legitimacy with the local people. The illegal use of wildlife became the only value that game retained for local people (Carruthers, 1995; Duffy, 2000).

The attitude of rural people towards natural resources of which they had lost control became/is “short-term”, “I better get it while I can, since if I don’t shoot it, snare it, chop it down or hook it someone else will”. Yes, it can be argued that the “live for today” mentality that rural Africans are continually blamed for did

not entirely emanate directly from them, but was as much the result of the pathetic elitist colonial policies imposed upon them.

“The lack of attention to human needs and aspirations, traditional knowledge and management systems has in some cases resulted in increased encroachment and poaching, as well as sabotage to wild habitat (Ghai, 1995;³⁹ Kothari, Singh & Suri, 1995; Kothari, Suri & Singh, 1996 all *In: Roe, et al., 2000*). This trend, in turn, reinforced the (commonly advocated) protectionist argument that local people do not have the knowledge, the will or the training to undertake sustainable wildlife management (IIED, 1994 *In: Roe, et al., 2000*). As human populations continued to grow rapidly, demands on remaining resources increased, leading to increasing environmental degradation and further conflict. ‘Social conflicts have grown in and around many protected areas and conservation goals themselves have frequently been threatened’ (Ghai, 1995 *In: Roe, et al., 2000*)” (*Roe, et al., 2000*).

Enforcement by the state was inadequate, while local controls had been lost. When the European powers substituted their law for local law, they were unaware of how much damage this action would cause.

“Now I know the European should have left you alone. We have set borders where there existed none and have often drawn the limits of your countries with the stroke of a pen, regardless of your race, your breed, your tribe...We wanted European’s law to erase your Black man’s law, and now that we are gone you are deprived of both. Africa, where are we headed” (Tré-Hardy, 1997)?

This disenfranchisement and loss of control over both access and eventually sustainable management happened not only with wildlife but also with fishery (Rajonson, DeGeorges & Booth, 1991; Owino, 1999) and forestry resources (DeGeorges, 1992).

³⁹ Note: Full reference for Ghai, 1995 not given in bibliography of report. Believed to be Ghai, 1992?

3.7.1 Open Access Resources in Niokolo Koba National Park

The Niokolo Koba National Park, Senegal, serves as a fine example of the classical African park established at the end of the colonial era. The Bassari hunter gatherers were thrown out of the park, losing legal access to their villages, traditional hunting grounds, sacred forests and burial grounds. Typical of many end-of-colonial era administrations and until about 1986, the national parks administration was run by “mi colonel”, Andre Dupuy a former foreign legionnaire. His “management philosophy” was “militaristic” consisting of maneuvers that rotated 200 armed guards through the park with M36 rifles to keep the local people out. The Bassari refused to accept the boundaries, considering it a “government and white man’s park”. Every year, confrontations between park personnel and the Bassari resulted in deaths on both sides. When commercial meat and ivory hunters came on camel or horse from Mali and Mauritania, the local people around the park turned their heads and/or aided and abetted the commercial poachers (DeGeorges, 1992). In the 1980s there were only 50 elephants left, while in 2002 there were only about five remaining (Mauvais, 2002).

3.7.2 Open Access Resources, Azna and Toubou Hunters of Niger

The Azna and Toubou of Niger were commercial hunters, which are believed to be excellent examples of how centralized control from colonialism turned wildlife into an “Open Access Resource” permitting ”nomadic hunters” to “mine wildlife” without the local controls of chiefs, elders and hunting guilds, which would have existed in pre-colonial times.

The Azna were specialists in hunting lion with poisoned arrows, using occult forces to render the hunter invisible to the lion, which was shot at 25-30 meters

(Mariko, 1981). Nicolas (1950 *In:* Mariko, 1981) explained how Azna hunters, further south were ruthless commercial hunters. They mounted major expeditions with pack animals and horses to chase game and hunted young animals during the rainy season while following game herds. During winter (December and January), when game concentrated around waterholes, they used fire to drive game towards traps until it was eliminated and then moved on. Mariko (1981) believes the fact that this type of “destructive” hunting was allowed with no controls is one of the primary reasons that so little game is left in Niger.

The Toubou were known as the black nomads of the Sahara, hunting collectively on horse/camel and making use of the javelin or throwing knife, saber and club. They also erected nets across passages, where horsemen accompanied by greyhounds (dogs) drove gazelles, addax and oryx. The feet of the antelope became tangled in the nets and were finished off with lances, hatchets, sabers and javelins. The hunting families ate the organs, but the meat was dried and sold to sedentary populations to the south, especially in Nigeria under the name *Margui*. The skins were sold to local artisans to make handbags, belts, shoes, rugs, cushions, satchels/saddlebags, etc. Mariko (1981) believes that this practice required no specialization as with “professional traditional hunters”, with little courage, skills or other qualities. He believed this to be non-selective hunting resulting in the extermination of males, females, young, etc. and both protected and unprotected species, and considered it a slaughter. Centralized government was unable to control this indiscriminant killing and without traditional local controls, which had been eliminated by colonialism, it was the end of the game! This kind of anarchic commercial poaching is continuing the elimination of wildlife in countries like the nearby Central African Republic as Sub-Saharan Africa enters the 21st century (see Chapter 10, Section 10.3.2.2, 2001, CITES and the ESA will not save wildlife in RCA's savanna areas. Wildlife in a crisis situation, the safari industry cries out but no one listens).

3.7.3 Open Access Resources among the Valley Bisa

In the Luangwa Valley of Zambia live the Bisa, a traditional hunting and agricultural society. The role of lineage, elders and hunting guilds in managing wildlife among the Valley Bisa is described in the previous chapter. Hunting was made illegal for Africans in 1891 (Marks, 1984), but legal for white residents and expatriates. The first game reserves were established in the 20th century as exclusion zones for Africans, leading the Bisa to believe that Europeans were more interested in wildlife than people (Marks, 1976).

By the beginning of the 20th century, the authority of hunting guilds to control access over and manage wildlife waned due to: 1) the introduction of the muzzle loader allowing individual as opposed to cooperative efforts to bring down game, 2) labor migration to work in mines and as domestic servants to Europeans drained the ranks of the guilds, and 3) failed attempts at centralized control over wildlife by the colonial power (Marks, 1976). The disappearance or degeneration of hunting guilds, eroding the authority of the chief and centralized control over wildlife by colonial government, undermined local control over wildlife and other natural resources managed as “Common Property Resources” turning them into centrally controlled “Open Access Resources”.

The exodus of hunting-aged men to urban centers in the first half of the 20th century actually took some pressure off the game and resulted in increasing wildlife populations. Up until the 1960s, hunting was for subsistence purposes, game was abundant around villages and most hunting took place within three km of the village by a few hunters with a muzzleloader, who were sanctioned and controlled by the lineage. Up until the 1960s, Valley Bisa hunters mainly hunted adult males of the four key hunted species; buffalo, impala, warthog and

waterbuck – and thus had little impact on the survival and dynamics of ungulate populations (Marks, 1976).

State regulations were poorly enforced and ineffective. By the mid-1960s, seven game guards (Marks, 1976) were placed in Luangwa Valley to stem the illegal and increasing demand of the “commercial trade” in bushmeat from growing urban centers. This proved ineffective in stopping resident hunters (Marks, 1976). The opening of Luangwa Valley to vehicular traffic and the increasing availability of more effective smokeless powder rifles and shotguns owned by non-lineage members increased hunting success, and the entry of hunters into a moneyed economy, as well as the loss of many traditional controls over access to wildlife and the subsistence level of exploitation (Marks, 1976). Buffalo, zebra (now killed for their skins) numbers, as well as tusk size of harvested elephants, among others, all apparently decreased from increased hunting pressure as a result of the external market economy (Marks, 1984). Half the bushmeat consumed by locals in the Valley was provided by outsiders, diminishing the prestige of traditional hunting guilds and their importance as a pathway to leadership within the community as a wildlife management body, as well as a bond to retain social, economic and political norms within the Bisa society (Marks, 1976). Unregulated and illegal commercial elephant hunting for meat and ivory in the 1970s and 80s resulted in elephant populations in the Luangwa Valley plummeting from 100,000 (Caughley & Goddard, 1975 *In:* African Advisory Board, 2000a) to as low as 15,000 by the mid-1980s (Child & Clayton, 2002).

3.7.4 Open Access Resources, Madagascar

Madagascar has a tradition of environmental conservation, expressed over the centuries as a set of rules establishing natural reserves for religious purposes such as the *ala-fady* or “forbidden forests”. At Aankazomborona Fokotany of

Madagascar, fishing pressure is controlled by *fadys* (closures) on Tuesdays and Thursdays, and certain lakes are reserved for subsistence purposes by a moratorium on commercial fishing. Until the late 19th century, Madagascar enjoyed a balance between population (approximately 2 million people) growth and environment. Low population densities made such traditional practices as *tavy* or “*slash and burn*” agriculture with 20-30 year rotational cycles both economically and environmentally sound. As on the African mainland, given today’s population of about 16 million such, practices as *tavy* are no longer sustainable, and along with uncontrolled burning, are causing a major loss of forest habitat.

When the French colonized Madagascar in the late 19th century, centralized management structures disenfranchised rural resource users and ignored traditional controls and management systems. Many natural areas that were once controlled by specific communities became “open access resource areas” where uncontrolled exploitation led to accelerated environmental degradation.

The situation has now become alarming to the world’s conservation community, since Madagascar houses one of the most biologically diverse plant and animal communities on earth. Approximately, 86% of Madagascar’s plant species, 95% of its reptiles, 65% of its bird species and 93% of its primates are endemic, being found nowhere else in the world.

Much of the island’s biodiversity depends on endemic forest ecosystems, ranging from rainforests in the east to spiny forests in the south and southwest. It is estimated that 80% of Madagascar’s original forest cover has disappeared, or has been severely degraded since the island was first inhabited some 2000 years ago. Between 1950 and 1985, rainforests on Madagascar’s eastern escarpment and benchland declined by 50% from 7.6 to 3.8 million hectares. This amounted to an

average rate of forest clearance of 110,000 ha/year during this period. An average soil loss of 25 tons/hectare/year to 16 times this amount in steep areas of high rainfall occurred from deforestation and poor agricultural practices. By 1985, most of Madagascar's remaining forests were on steep slopes, inaccessibility being the main reason for conservation. If current trends are not reversed, almost all of Madagascar's forests will be damaged or destroyed within 20 years (Development Assistance Corporation, 1993). Over-grazing, especially in the Central Highlands, has contributed to the formation of massive gullies (*lavakas*) and thus to this erosion process (Cox, Rakotondrazafy & Rakotondramazava, 2004).

People are so poor that they have no time to worry about what they consider esoteric ideas such as biodiversity, conservation and environmentalism. When the first USAID multi-disciplinary team arrived in the early 1990s to address the above issues, rural people asked, "Why have you come so far to save lemurs? Lemurs! We eat lemurs". This is a similar response to what many rural Africans give regarding wildlife, seeing it as a human, animal and crop pest, or a short-term resource, i.e. 'nyama' (meat) to eat.

3.8 LAND COMPRESSION

Colonial mono-culture economies, the take over of prime land by European settlers, and the creation of parks and protected areas compressed Africans into marginal areas that could not support them and resulted in further land and habitat degradation, which was blamed mostly on Africa's backwardness.

"From the perspective of peoples in Africa, Asia, the Pacific, and what became the Americas, colonization was essentially an Europeanization involving the imposition of European concepts of sovereignty, religion, and civilization. One effect, perhaps the crucial one, was the drastic reduction of indigenous peoples land

bases and their restriction to progressively smaller areas. In the United States, for example, Native Americans had surrendered 2 billion acres (810 million ha) through treaties by 1887, leaving a residual 140 million acres (57 million ha). Another 90 million acres (36 million ha) was lost through the allotment policy that operated to privatize Native American lands until 1934. As a result, today Native Americans retain barely 5% of the United States...The land was defined as *terra nullius* (empty land) and assumed to be without the impediment of indigenous rights. As in Africa, when their lands were lost, indigenous peoples also lost livelihoods, graves and other sacred sites, history -- for history was written on the landscape -- and much of their religions. Europeans and their colonial offshoots offered in return their form of civilization, based on Christianity, individualism, and private property ownership" (Hitchcock, 2003a).

3.8.1 Land Compression among the Last Hunters and Gatherers, Ju/'hoansi of Nyae Nyae, Eastern Bushmanland, Namibia

In 1950, 1,200 Ju/'hoansi were still supporting themselves by hunting and gathering in an area of about 90,650 km² (35,000 mi²) (Weaver & Skyer, 2003) stretching north and south along the Namibia/Botswana border. They were the last independent self-sufficient hunter gatherers in Southern Africa. In Nyae Nyae in the 1950s, the Ju/'hoansi neither recognized nor were subject to any administrative authority beyond the rules and values of their own society (Marshall & Ritchie, 2003). Governmental decisions in South West Africa in 1970 saw 40,000 km² of the Ju/'hoansi's ancestral territory ceded to other groups, the Herero to the south and the Kavango to the north. A portion of the Ju/'hoansi territory was also designated as the Kaudum (!Aodom) Game Reserve. Eventually, the Ju/'hoansi were left with approximately 9,030 km² (Weaver & Skyer, 2003) or only 10% of their original ancestral land. The Ju/'hoansi were encouraged to move to Tjum!kui, (Tsumkwe) where a borehole was drilled in 1960. They were then trained in agriculture while encouraged to continue foraging (Hitchcock, 2003b). Smith (1992) argues that encouraging pastoralism

among the Ju/'hoansi has diminished the contribution of women to society and thus their social status. Cattle and protection against predation has become a man's job. Men and boys are more likely to come in contact with Herero and Tswana herders learning other languages and developing a more outward looking view of the world. Women's fertility rates increase with a higher fat diet from milk, and without birth control, this increases their work load. The net result of the above is greater separation between men and women, and less equality than found in traditional foraging lifestyles.

Residents of Tjum!kui were hired to clear fields and build roads. Some worked in missionaries' homes, and at odd jobs around the settlement. Alcoholism and unemployment became a major problem afflicting their lives, compounded by social disruption from the Bushmen having been used to fight in the liberation wars of Southern Africa. In spite of the fact that the government had stipulated that people in Nyae Nyae could hunt as long as they used traditional weapons and hunting techniques, Ju/'hoansi men were arrested for hunting animals that were not protected under South West African government conservation laws (Hitchcock, 2003b). Alcoholism and social dissolution continues to be a problem (see Chapter 9, Section 9.7.6.4, CBNRM will not create a "middleclass" in rural Africa, Life, Namibia).

3.8.2 Land Compression among the Bisa, Luangwa Valley, Zambia

In an attempt to stop slash and burn agriculture (*chitemene*), in 1906, the colonial government prohibited the pollarding (ring barking) of trees. A policy of concentration, amalgamating villages of 20 huts or less into large villages, disrupted social relationships and likely affected fallow periods and the localized overuse of other resources (e.g., wildlife), placing more pressure locally on the

land. Local people had preferences for small settlements, where the opportunity to become a headman (*mwine muzi*) of a village increased (Marks, 1976).

3.8.3 Land Compression and British Colonial Policy, Tanzania (Tanganyika)

The British took over from the Germans, following WWI. Whereas the German policy in Tanganyika was reclamation; bush clearance and elimination (shooting) of wild animals (MacLean, 1930 *In: Kjekshus, 1977*), the British implemented the “Desart Policy” which took scattered residents and villages and concentrated them into areas believed to have fertile soils and permanent water – similar to the French policy of *regroupement* (see Section 3.1.4.1, Francophone colonial Africa). Bush was cleared for permanent settlement with the aim of 259-people/km² (100-people/mi²), and 1,000 families as a minimal concentration. On paper, it seemed the prospects for success were self-evident as were later schemes of block-farming, village settlement and *Ujama'a* Villages (see Chapter 11, Section 11.8.4, Food Aid and *Ujama'a* Villages in Tanzania).

It “ ‘will make easier the task of changing a disease-ridden and backward horde of savages into a disciplined and prosperous community’ ” (PCAR, 1933 *In: Kjekshus, 1977*).

By 1934, most of the concentration schemes were in the tsetse fly belt of western Tanganyika, west of the Mwanza – Tabora – Mbeya road, mostly in the northern half, today’s Kigoma, Shiunyanga and Kagera Districts and to a lesser degree in the Tabora and Rukwa Districts. Concentrations continued through the 1940s and early 1950s

These concentration schemes failed as nuclei of economic reconstruction. The rotational/fallow system broke down and the only land cultivated was in the

immediate surroundings of the village. Without the rotational and fallow cycle, it is likely that the productivity of this land was drastically reduced in a few short years, while the bush would have encroached to the edge of these concentrations creating habitat for the tsetse fly. It was estimated that 85% of the people lived on 33% of the land of the original scheme, the remainder being abandoned (TNA 30600, *In: Kjekshus, 1977*). A botanist visited 27 sites in western Tanzania and pointed to their deficiencies as economic entities, the absence of cattle, forcing people to rely on shifting cultivation, frequent soil exhaustion and soil erosion (TNA 31351 *In: Kjekshus, 1977*).

Furthermore, the abandonment of vast tracts of land left uncultivated and ungrazed by removing human populations led to the invasion/return of bush, wildlife and tsetse fly (Apted, 1962 *In: Kjekshus, 1977*; MacKenzie, 1997) that ‘*primitive man*’ had controlled.

3.8.4 Land Compression and the Maasai of Kenya and Tanzania

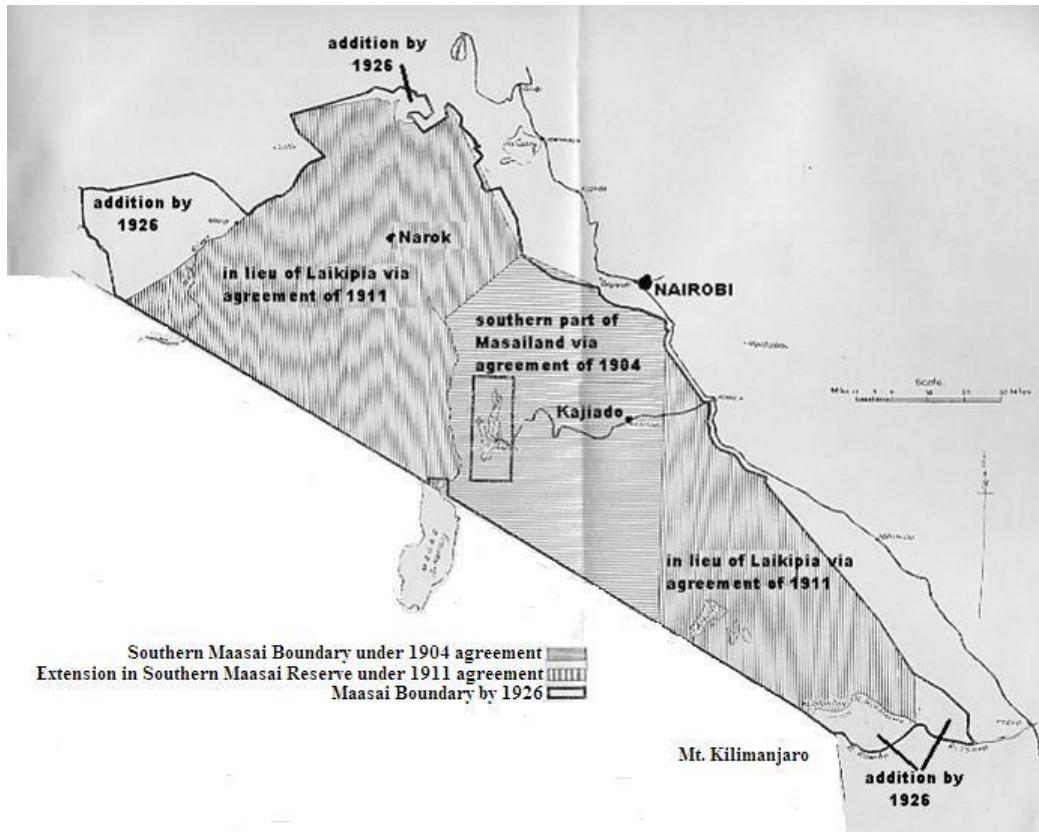

In 1904, the colonial government of Kenya compelled the Maasai to vacate fertile highlands of the Great Rift Valley, giving them other land for compensation, which they were forced to abandon again in 1911 to semi-arid land south of the railway line (Mombassa to Kampala) due to an increase in white settlers (Adams & McShane, 1992; Cheeseman, 2002).

According to Parker (2005a) based upon a review of the Kenya Land Commission report of 1933 and other research:

“Prior to the 1880s, the Maasai were militarily powerful and controlled the plains of highland Kenya (and northern Tanzania). They were divided into clans, the most powerful of which were the Uasin Gishu and the Laikipiak who respectively occupied the Uasin Gishu and Laikipia plateaux. In the c.1870s the Laibonic Batiaan combined

the clans first (warring and defeating) against the Uasin Gishu then the Laikipiak, breaking them totally, leaving only small groups as refugees. In 1883, shortly after the Uasin Gishu and Laikipiak were defeated, an epidemic of bovine pleuro-pneumonia swept through the Maasai herds. Before they recovered from this the Great Rinderpest pandemic swept through the continent and by the time it was over the Maasai had lost most of their cattle. In these circumstances a new civil war broke out led by two of Batiaan's sons – Sendeyu and Ol-Onana. By 1895 it was estimated that there were little over 40,000 Maasai in all of Kenya. In the Land Commission's view, '... but for British Protection, the Maasai would have become a factor of comparatively minor importance and their country might have been gradually occupied by other tribes.' The Government's view was, given their low numbers, that the Maasai had undoubted historical right to live in their lands, but that as a matter of principle it questioned the right of relatively few, wandering nomads to keep others out of more land than they could use. The latter view was given a sharp edge by the Government's simultaneous wish to settle white immigrants.

To make room for European settlement (Parker, 2005a)...the Maasai were persuaded (in 1904) by Government to confine themselves to two reserves: one on the Laikipia Plateau and the other being some 11,136 km² in what is now central Kajiado District (Figure 3.2). Splitting the Maasai in two led to social and administrative difficulties for the people themselves, the administrators and the owners of land between the northern and southern Maasai Reserves. Again, this was added to by Government's desire for yet more land for white immigrants. This led to the proposal that the northern Maasai (largely Purko) should move into a much enlarged single Maasai Reserve in the south. Codified as the Anglo-Maasai Agreement of 1911, the Maasai lost the Laikipia Plateau (to European settlers), and were allocated what is now Narok District and the triangle below the Siria escarpment in Trans-Mara. Subsequently, 2,355 km² in Trans-Mara and 9,550 km² of modern Kajiado District to the east of what had been agreed in 1904, were added: as were other smaller peripheral areas. By 1933 the Maasai Reserve was 37,880 km² in which there were 48,381 people giving a human density of 1.3 Maasai per km². In 1930, the official estimate was that they owned 720,000 cattle, 820,450 sheep and goats and 171,800 donkeys.

Figure 3.2: Maasai reserve boundaries, Kenya in 1904, 1911 and 1926

By 1933, when the prospect of alienating more land for white settlement was no longer a possibility, the Land Commission was clearly concerned about the inequitable distribution of land between tribes in Kenya. It gently questioned the sense of setting aside so much land for so few people, and suggested that other people such as the Kikuyu – who were already at densities of $57/\text{km}^2$ – should be allowed into the Maasai Reserve. The British Government stood by its commitment to the Maasai after 1911. However, after Independence in 1963, the reality of the now far greater discrepancies in densities between the Maasai and agricultural neighbours manifest itself. When the white settlers were bought out, the land of which the Maasai had been divested in 1904 and 1911 did not revert to them, but to the Kikuyu, Wakamba, Kalenjin, Luhya and other agriculturalists. With the perspectives of increasing time, it might be argued that given the asymmetry of expansion between agricultural tribes and pastoralists

would have produced the same end effect as the colonial policies. Indeed, they will be seen as a small blip in an inevitable process”.

In Tanganyika, the Maasai were forced to move in the 1940s as white settlers arrived to claim the plains between Mt. Meru and Mt. Kilimanjaro, as well as most of the fertile lands near Ngorongoro (Adams & McShane, 1992).

Following independence in 1961, colonial administrators and African leaders failed to understand how the Maasai fit into their ecological niche, considering these herdsmen a threat to wildlife (Adams & McShane, 1992).

Between the late 1940s and 1970, seven protected areas were created in Maasai areas, further restricting the Maasai people’s range: Nairobi, Amboseli, Tsavo National Parks and the Maasai Mara in Kenya, and Serengeti, Tarangire and Lake Manyara National Parks in Tanzania. Many of these parks/reserves have been managed as isolated islands of game protected from people like the Maasai (Adams & McShane, 1992). The compression of Maasai into smaller and smaller areas bordering these parks has resulted in over-grazing. However, this wildlife is not contained entirely within these reserves, moving out onto rainy season grazing areas belonging to the Maasai. In fact, it is believed that in Kenya, 80% of the wildlife is found or dependent on 80% of the critical wildlife habitat outside parks and reserves (DeGeorges, 1992a; Cheeseman, 2002). The Maasai were so dissatisfied with the loss of Amboseli as a dry season grazing area in 1977 that almost all the rhino were exterminated by them “to show their political dissatisfaction with their prospects” in the park (MacKinnon, MacKinnon, Child & Thorsell, 1986 *In:* Wels, 2000). Between the 1950s and 1977 the rhino population dropped in/around Amboseli from 150 to 15, with many found dead as a result of “revenge killings” from a Maasai spear, often with their horns still in place (Rosenblum & Williamson, 1987) (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between

pastoralists and small farmers, Amboseli and Maasai Mara, Kenya and Chapter 11, Section 11.11.9 Kenya Wildlife Service (KWS) – Living on Donor Handouts, Negative Impact On Kenya's Wildlife Outside Parks). This is also true for Tanzanian reserves, where for instance, many species of ungulate from the Tarangire National Park (TNP) move to the Simanjiro Plains of Southern Maasailand during the rainy season to drop their young (see Chapter 9, Section 9.7.8.2 “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

To appease the Maasai, the colonial governments constructed dams and drilled boreholes where there were no permanent water supplies. Year round access to water, often in rainy season dispersal areas, along with improved veterinary services led to an increase in the numbers of cattle, goats and sheep, and increasing stress on these semi-arid rangelands (Adams & McShane, 1992), resulting in over-grazing and bush encroachment. Well-intentioned missionaries are continuing this practice, with little understanding for the potential ramifications of over-grazing as they take extensive pastoralists into intensive management systems for which they have no training. These boreholes have also tilted the ratio in favor of water dependent cattle over water independent goats, accelerating bush encroachment as grazers are now favored over browsers (Nyika, *pers. comm.*). More detailed discussions on the impacts of boreholes on traditional pastoralism, wildlife and the environment are discussed in Chapter 6.

3.8.5 Land Compression, Wakamba and the Black Rhino of Machakos Kenya

The arrival of a British administration created new conditions of human settlement that changed the landscape and introduced the transformation of soils and vegetation. British rule protected the Wakamba from Maasai raids. The Wakamba tribe, an agricultural society who hunted, had increased six-fold under

British protection, and land was needed for farming. Fixed boundaries resulted in land compression and along with drought created the barren eroded landscape observed in the 1920s. From 1931-36, severe droughts compounded this problem resulting in degradation due to (McCann, 1999) the:

- Hemming in of the Wakamba herds;
- Encroachment of agriculture on the lower slopes and plains; and
- Effects of drought on vegetation cover.

Colonial policies, with little understanding of local ecology or farming/grazing systems, resulted in the irreversible degradation of the land. Over-grazing combined with the colonial policy forbidding fire, resulted in the loss of savanna and increased bush encroachment and a decline in grazing capacity. Desertification did not occur, but just the opposite, namely bush encroachment. By the 1940s, needing more land, John Hunter, a famous big game hunter, was commissioned by the Machakos District Commissioner, to clear rhinos and other dangerous game out of the area. This would have been the “useless” tsetse fly ridden bush to the southeast, which likely contained poor soils for agriculture, but which was important habitat to wildlife. This area was one of the greatest black rhino areas in the world, John Hunter shooting over 1,000 to clear the way for farming (Hunter, 1952).

The sad thing is that this scheme was eventually abandoned (Holman, 1967). To this day, the majority of Wakamba living in this area on marginal agricultural lands eke out an existence living in abject poverty and relying on donor food aid (Nyika, *pers. comm.*). The only concentration of wildlife in the area today is found on highly successful Wakamba cooperative ranches⁴⁰, which have been

⁴⁰ A “cooperative ranch” is an African owned large-scale ranch generally previously owned by Europeans consisting of up to 2000 members and kept intact and managed as an economically viable unit. Members of the cooperative are the equivalent of shareholders and receive annual

kept intact and have not been subdivided as was done by Kikuyu land buying companies in Laikipia (Powys, 2003). Wildlife on these Machakos cooperative ranches must be continually protected from Wakamba poachers coming across the fences (Stanley, *pers. comm.*).

3.9 ECO-GENOCIDE

Unfortunately, the policy of parks and protected areas has impoverished and destroyed cultures of local people. “

Their (Maasai's) story is about and how Africa's spaces have been set aside for preservation and tourism. Africa may be a vast continent, but the land that has been turned into parks wasn't idle land. Scores of tribes and millions of people have been dispossessed and it is still happening” (Bonner, 1993).

“Foreign aid”, through Western NGOs, government and even African conservationists, is willingly creating exclusion zones in the 21st century that is adversely impacting local cultures. This will be discussed in more detail in chapters 9 and 11, on Community-Based Natural Resource Management (CBNRM) and Foreign Aid, respectively, where case studies are also presented.

In essence, for many indigenous Africans, conservation policies have meant a loss of anchors linked to their cultural and social identities. All over Sub-Saharan Africa one observes incidences of indigenous people kicked out of their traditional world (e.g., even in the 20th and 21st centuries; the San were forced to leave the Central Kalahari Game Reserve (CKGR), the Baka Pygmies expelled from their forests in Southeastern Cameroon, the Maasai were chased off their lands), and all this to create parks, hunting blocks, game reserves and logging

dividends. This is as opposed to a “group ranch”, which is a piece of land set aside for clans living subsistence lifestyles in pastoral areas; the Maasai group ranches of Mukogodo, Kajiado, Amboseli, etc. (Powys, 2003)

concessions. However, once expelled, the people are inadequately prepared to join in the new outside world to which they are exposed, mostly a Western and increasingly a global world in which they are ill prepared to compete, both psychologically and intellectually, lacking an appropriate education. Alcoholism is a major escape, and the situation is generally similar to problems in North America on Indian reservations.

Turnbull (1972) aptly explains the changes which colonialism imparted in destroying the lives of traditional hunting and gathering societies; traditional

"hunters, must have been as much a part of their natural world as the mountains and winds and rains and the very game they hunted and wild fruits they gathered. Wherever they went there was beauty, for as Didigwari (an Ik god) had told them, there would always be enough. But when they became imprisoned in one tiny corner, the world became something cruel and hostile and in their lives cruelty took the place of love".

The same could be said of nomadic herders whose lives have been irreparably damaged by colonial and post-colonial conservation policies.

Interestingly enough, Richard Meinertzhagen, a famous British intelligence officer, who was known for his brutality in subduing the natives, in fact equating humans with game bags (Meinertzhagen, 1957 *In:* MacKenzie, 1997), and Fredrick Jackson, deputy commissioner of the East African Protectorate, were in opposition to Meinertzhagen's relative and Commissioner, Sir Charles Eliot. Eliot favored native reserves as they could provide cheap labor to the European economy, while Jackson and Meinertzhagen disapproved of settlers and believed that the wildlife and the people should be left alone and should be managed in a natural state. Jackson was distrusting of "non-sporting settlers" and was instrumental in creating game conservation policies and a game department (MacKenzie, 1997).

3.9.1 Eco-Genocide and the Elephant People

On April 1, 1948, about 20,898 km² (8,069 mi²) in southeastern Kenya were proclaimed a game sanctuary and called Tsavo National Park. This was considered useless for farming or ranching, largely no-man's land, claimed by no tribe as their territory, a perception that was soon to change. The Waliangulu, Liangulu or, as they call themselves, the Wata were a little known tribe of perhaps a few thousand (Parker & Amin, 1983), less than 5,000 (Parker, 2004) to some say up to 20,000 people (Kassam & Bashuna, 2002), who often adopted the dress and language of their neighbors and became integrated into the societies of the Giriama, Digo, Duruma and Orma (Parker & Amin, 1983). They were divided into clans along the same lines as the Orma and spoke the Cushitic Orma pastoralist language Oromo (Parker, 2004). Parker (2004) leaves some doubt as to whether the militarily organized Orma subjugated the Wata to control the trade in ivory, or whether the Wata were a junior friend in the ivory trade. Inter-marriage between the two groups occurred.

In coastal Kenya, they were also called *Wasanye* stemming from the Bantu word for ironsmith. This skill had been passed on in reverse of typical trends, from a "primitive" hunter gatherer society to more sophisticated agriculturists and herders. Across the entire continent, only the Wata and closely related Boni north of the Tana River, Kenya, specialized in elephant hunting. This is believed to have been due to a climate that allowed appropriate habitat and thus elephant to flourish from southern Somalia to coastal Kenya while providing easy access to trading posts linked to the Mediterranean, Middle Eastern and Indus civilizations. It must not be forgotten that by 500 BC, Asian elephants in Syria and Asia Minor were extinct, making Africa the major source of ivory (Parker, 2004). Parker

(2004) suggests that the Wata were not a primitive hunter gatherer group in the classical sense, but a 2000 year old or older ivory producing culture.

There were about 200 actual elephant hunters among them (Kassam & Bashuna, 2002). The Wata were the “true elephant people of Africa”, specializing in hunting elephant. Other less specialized elephant hunting tribes included the Giriama and Wakamba (Holman, 1967; Parker & Amin, 1983). The Wata hunted with a long bow, measuring nearly six feet with draw weights averaging 100-131 pounds (Parker & Amin, 1983), ranging up to 170 pounds (Parker, 2004). The Wata mostly took spleen (Holman, 1967)/intestine shots (Parker & Amin, 1983), using a very powerful poison called *Hada* provided by the cultivating Giriama tribe, of which the dominant ingredient was extracted (wood, barks, roots and twigs) from the *Muriju* or *Wabayo* bush (*Acokanthera schimperi*). An elephant with a well-placed shot would go no more than 200 meters before dropping (Parker & Amin, 1983 *In:* Kassam & Bashuna, 2002). Parker (2004) estimates that it took about 24 minutes to die from the time the arrow entered, while elsewhere (Parker, 2001 *In:* Parker & Bleazard, 2001) the estimated period is reduced to 15 minutes. Parker argues that this bow/arrow/poison combination was a sophisticated weapon, which modern technology would have a hard time improving upon and that it was maybe more efficient than a modern rifle. Where as a musket ball or bullet has to pass through a vital organ to kill, poison lodged in the blood stream is fatal whether the arrow hits the heel or the brain (Parker & Amin, 1983).

In 1956, the Wata, Wakamba and Giriama were stopped from hunting elephant, which up until then had been their main livelihood in Tsavo National Park. Classified as poachers by the Kenyan colonial laws, they were arrested and placed in jobs with professional hunters as trackers and guides. Some were also employed as game scouts with the Game Department or National Parks. Most,

however, were unemployed, with a risk that they would go back to their old ways if nothing was done about the situation (Holman, 1967). Innovative thinking would be required. Those responsible for ending the hunting life of the Wata were troubled by their fate, and envied their freedom, their knowledge of bush lore and their innate decency. The area where they lived was so dry that farming would only bring a yield once in five years, so this way of life was not practical; thus the birth of the Galana River Management Scheme, or Galana Scheme (Blankenship, *et al.*, 1990), also called the Waliangulu Scheme (Parker, 2004) established in 1958. It was conceived by Noel M. Simon, David L. W. Sheldrick and I. S. C (Ian) Parker (Blankenship, *et al.*, 1990) and Bill Woodley (Parker, 2004). The idea was to use the bush skills of the Wata in a sustainable elephant cropping (form of game cropping)⁴¹ scheme in a 7,770 km² (3,000 mi²) area along the eastern border of the Tsavo Park (Simon, 1962; Parker & Amin, 1983; Parker, 2004). Parker (2004), as a warden in the Kenyan Game Department, unlike many of his colleagues, felt that Africans should be allowed to carry out traditional hunting. The East African Professional Hunters Association opposed the scheme (Parker, 2001 *In: Parker & Bleazard, 2001*).

Between the initial plan in 1958 and its implementation in April 1960, the scheme went conceptually from very hands-off management, in which the Wata would continue their traditional hunting but with rifles instead of bows, while government officials would mainly assure compliance with the elephant quota and marketing of ivory by-products, to a program marked by inflexible bureaucratic controls in which the Wata became closely supervised employees (Parker, 2001 *In: Parker & Bleazard, 2001*). Problems immediately arose, especially the inability of the Wata to adapt to a very rigid militaristic, hierarchical and

⁴¹ Cropping is the sustainable harvest of meat, skins and other by-products from a game population for economic purposes. Culling is reduction of a game population as part of a management strategy. This program appears to be a hybrid of the two definitions. Ultimately, these elephants needed culling to reduce their population, something that never happened.

controlled approach to management, as opposed to an absence of rigid social organization in their own society.

While professional hunters and clients agreed that the revenues from visiting sportsmen should go to the Wata, the Game Department ruled that they would go to the department (Parker & Amin, 1983; Parker, 2001 *In: Parker & Bleazard, 2001*). However, Parker (2004) indicates that income derived from elephant cropping, including meat, hides and horns from all animals could be reinvested back into the project, except revenue from the most valuable resource, ivory, that had to go to the treasury. Parker (2001 *In: Parker & Bleazard, 2001*; Parker, 2004) also states that the ivory was sold separately and after major negotiations returned by the Kenya Treasury to the scheme as a grant.

Since traditional weapons were illegal, the Wata were forced to use rifles, for which they had contempt. They claimed the noise from the rifles drove many elephants into Tsavo, a safe haven, where they remained since no harvesting was allowed in the park. The cropping program assumed the existence of a single elephant population in the Tsavo/Galana Complex, which could be controlled by harvesting outside the park, while it turned out there were a number of herds making the task much more complex. It became clear that the population within Tsavo would have to be solved within Tsavo and not from the outside (Parker & Amin, 1983). The annual quota of 200 elephants was never attained (Parker, 2001 *In: Parker & Bleazard, 2001*).

As a result, the elephant populations exploded in Tsavo, exceeding the carrying capacity of the area to feed them, compounded by bush fires and a drought. By the early 1960s, it was estimated that 40,000 elephant lived in the Tsavo/Galana Complex. Concern existed that the elephant populations were too numerous, opening up the bush and contributing to the death of hundreds of black rhino from

starvation during the 1960/61 drought. Culling schemes to reduce the elephant population in the Tsavo Park recommended by wildlife biologists such as Dr. Richard Laws were rejected by National Parks, because of the National Parks Ordinance, which stated that parks were established to protect wildlife. This was interpreted as meaning no mass-killing programs without fully understanding the consequences (Parker & Amin, 1983). For unknown reasons David L. W. Sheldrick, who first supported elephant reduction reversed his position (Parker, 2004). Today, we would call this the “Precautionary Principle”, as opposed to the Southern African “Adaptive Management Principle”, approach of taking preemptive conservative measures based upon existing knowledge, while monitoring the outcome and filling data gaps to make better decisions, which the biologists and managers were recommending (see Chapter 9 for further discussion on the precautionary versus adaptive management principles). With no active management “natural regulation approach” natural recruitment and elephant compression into smaller areas from increasing human populations, the 1970-71 drought resulted in major elephant die-off in Tsavo (Parker & Amin, 1983; Parker, 2004) as well as a black rhino crash (Parker, 2004).

Two key factors believed to have contributed to this population crash were that 1) the elephants may have reached their carrying capacity and 2) the elephants appear to have been compressed into a region with low rainfall (Owen-Smith, 1992) by both growing human populations and the failed culling attempts outside of the park (Parker & Amin, 1983). To the west of the park, Kamba agricultural expansion displaced elephant into Tsavo. In the early 1950s the Aruba Dam on the Voi River in Tsavo East provided permanent water where none had existed before, resulting in the park becoming dry season range when in the past it had served as wet season range. At the same time, the only natural permanent water in the vicinity, in the Sebaki River far to the east of the Tsavo boundary, became settled by humans at the Rei, Mido and Garbiti waterholes, denying them to

elephants as a dry season feeding grounds (Parker, 2004). Dispersal was not an option for the elephants as various populations of elephants became compressed into the park.

Once the pick-up ivory from the die-off was finished, a wave of poaching began. The estimated loss of elephant in the 1970/71 crash from the drought was 9,000 – 15,000 (Parker & Amin, 1983). The total estimated loss by 1980, which included poaching, was 30,000. This was directly attributable to over-population and mismanagement by foreign interests (Beard & Watson, 1980 *In:* Beard, 1988).

While not showing a monetary profit, the Galana Scheme in its first three and a half years grossed US\$ 108,000 (£40,000) from the sale of 36.5 tons of dried elephant meat sold mainly in Nairobi as biltong (mainly used as dog food); elephant ear and belly skins for leather, and elephant feet for waste-paper baskets and other wildlife curios (Parker, 1964 *In:* Blankenship, *et al.*, 1990). However, Parker (2001 *In:* Parker & Bleazard, 2001) estimated total income from sale of produce of US\$ 58,204 (£21,557) with a net profit of US\$ 21.6 (£8) in the first 3 and a half years of operation if capitol was paid off over 30 years at 5% interest. In other words, the Scheme broke even. The total income increased to over £40,000 over the same time frame if revenue from trophy hunting is included, but which, as noted, was not returned to the scheme.

Meanwhile, the Waliangulu Scheme became the Galana River Game Management Scheme, turning away from being a program to reintegrate the Wata into elephant/wildlife management into a cattle ranching moneymaking scheme (Parker & Amin, 1983; Blankenship, *et al.*, 1990). This was run by Galana Game and Ranching Limited made up of a consortium of American Martin Anderson and Kenyans Mike Prettejohn, Gilfrid Powys and Tony Dyer (Parker, 2001 *In:* Parker & Bleazard, 2001). The company built up to running 28,000 high quality

Boran cattle,⁴² fulfilling all predictions, but eventually had its 30 year lease terminated and ultimately failed since the Galana Scheme lost sight of the original simple goal of allowing the Wata to continue as traditional hunters (Parker, 2001 *In: Parker & Bleazard, 2001*).

Many Wata felt that their being stopped from hunting elephant was to allow the European to take their place through sport hunting (Parker & Amin, 1983). Ultimately, the day the Kenyan government refused the Scheme the right to market and benefit directly from the sale of ivory (e.g. marketed indirectly through Kenya Treasury), was the day the Wata lost faith, being certain the scheme was not to their advantage (Parker, 2004). Sociologically, the Galana Scheme was a failure (Parker & Amin, 1983), a form of eco-genocide that wiped out an entire culture and lifestyle that appeared to be living for thousands of years in balance with Kenya's elephants and other wildlife. Reflecting on the failure of the Galana Scheme, Parker (2004) states,

“how could we as very young white newcomers teach the Wata to live off elephants? With an elephant-dependent culture of great antiquity, surely they should have been the teachers?...The only role that Tony Seth-Smith and I should have played was marketing Wata hunting produce and ensuring that they did not exceed such quotas as may have been allocated to them. Other than this, the Wata should have been left to themselves”.

The tragedy is that in trying to save a wildlife species, they only succeeded in crashing the elephant population, destroying the habitat for other species such as the black rhino, greater and lesser kudu, gerenuk and bushbuck. In Africa today, animal populations are being increasingly confined within limited and unnatural

⁴² Boran cattle are found in southern Ethiopia, northern Kenya and southwestern Somalia. The Boran belongs to the East African Shorthorned Zebu type (see Chapter 1, Section 1.1.4, Origins of Domestic Livestock and Pastoralism in Africa) and is raised primarily for meat production. The Boran is a medium-size *Bos indicus* breed that shows high resistance to heat, ticks, and eye diseases. It can endure scarcity of water and can live on low quality feed (OSU, 2003).

boundaries. Within these boundaries, animal populations tend to increase up to – and then beyond – the limits of the food supply. In a world with finite resources, the elephant is second only to man in its capacity to inflict long-term irreversible damage on its environment. Not surprisingly under such conditions, the elephant is ravaged by many of the same symptoms as modern human: stress, violence, vandalism and heart disease (Laws, 1988 *In: Beard, 1988*). The question that should be asked is this:

“Should this species be allowed to find its own level in relentless competition with others for the world’s limited land and resources, or should the species be brought into balance with the environment and the other species that inhabit it. Today that species is the elephant” (Laws, 1988 *In: Beard, 1988*)

and one could argue the modern human (For further discussion over elephant management issues, see Chapter 10, Section 10.4.5, Does CITES Help Southern African Elephant Conservation?).

The greatest failure was in not trying to understand the traditions, economics and customs of the Wata and their integration into the Galana Scheme.

“Wata hunting was demonstrably the basis for a stable and nutritionally affluent way of life...they were better placed to be teachers than to be taught hunting...Had the original 1909 Game Laws been enforced, permitting their traditions to be followed legally, and had the government assisted them in marketing of game trophies, undoubtedly they could have continued their subsistence hunting for an extended time and earned considerable monetary income without depleting their game stocks” (Blankenship, *et al.*, 1990).

“Long before European ‘game-savers’ arrived on the scene, local hunting tribes such as the Wakamba, Waliangulu and Giriama coexisted with the elephants. It was only when the traditional hunters were rounded up and imprisoned for poaching that the elephant population began to expand and that breeding now

unchecked consumed the limited habitat" (Beard & Watson, 1980
In: Beard, 1988).

The age of the elephant people has passed, and Africa has "lost something special" in this passing, a unique culture virtually unknown to the outside world. Today, the majority of the Wata live on the margins of mainstream society. They eke out a meager existence making charcoal, supplying building poles, serving as watchmen in towns, or merely begging. The few who are better off keep some livestock, farm or engage in trade. They are despised due to their low economic status, and like other hunter-gatherers and former hunter-gatherers, they are subject to negative stereotyping. A Wata sociologist believes that this culture in the 21st century is on the verge of extinction and among other things needs to be recognized as an Oromo sub-group, be given educational opportunities, hunting rights, protection of its sacred shrines and be accorded UN protection as a minority group (Kassam & Bashuna, 2002). For all practical purposes, the Wata might already be considered culturally extinct since they can no longer hunt elephant and their way of life has been erased from the face of mother earth.

3.9.2 Eco-Genocide and the San of the Central Kalahari Game Reserve (CKGR), Botswana

The Central Kalahari has been occupied for hundreds of thousands of years by hunters and gatherers (e.g., G/ui, G//ana, and some Kua San), and since the early part of the first millennium AD by agro-pastoral populations (e.g., Bakgalagadi). The Central Kalahari Game Reserve (CKGR) was established in 1961, prior to independence (1966) to protect resident human populations (including San and Bakgalagadi), wildlife and the unique ecological landscape. It covers 52,347 km² (Hitchcock, 2002a) compared to the 48,000 km² Selous Game Reserve (SGR) that covers 5% of Tanzania's land surface (Baldus & Siege, 2002). At the time of its

creation there were an estimated 4-5,000 people residing in or having access rights to the reserve (Hitchcock, 2002a).

These people were allowed to hunt without licenses as long as they used traditional weapons (Hitchcock & Holm 1993 *In: Colchester*, 1994), such policies being referred to as “enforced primitivism” by the World Bank (Goodland, 1982 *In: Colchester*, 1994). Changes in hunting methods and the increased effectiveness of hunting from horseback, along with livestock grazing in the Central Kalahari, led many ecologists, NGOs and the Department of Wildlife and National Parks to believe that hunting should be stopped by residents of this reserve; the most effective way being to resettle them outside of the reserve. A July 15, 1986 government White Paper on remote area dwellers in the Central Kalahari Game Reserve (CKGR) recommended removing all settlements outside of the reserve. This was met with resistance by the residents, who asked, “*Who will guard the resources when we are gone*”? The Botswana government, against the wishes of Western indigenous rights groups, believed that they had the right to move people from a primitive lifestyle to a more modern one, that wealthy whites were trying to impose a separate development policy, and that the people of the Kalahari were attempting to secede from the nation-state of Botswana (Hitchcock, 2002a).

A “carrot and stick” approach was used to coax people out of the reserve. Cash compensation was promised to those leaving the reserve. Subtle threats were made of decreased government support to schools, health posts and drought relief. A few people were relocated in the late 1980s and early 1990s but many returned to the CKGR because of the limited availability of land and natural resources outside of the reserve. In 1993, the San formed the NGO “First People Of The Kalahari” to fight for their rights to remain in the (CKGR) arguing that the

Botswana Government was being influenced by mining companies, De Beers and Falconbridge (Hitchcock, 2002a).

By April 1997 at a Human Rights Commission meeting in Geneva, the Botswana government held that the Constitution would not let them treat the San (Basarwa) as if they were indistinguishable from wildlife— that is to allow the San to be part of the natural ecosystem. This therefore implied the need for their removal. In spite of protests, in May 1997, the Government of Botswana relocated over 1,100 people to two sites outside the CKGR (Hitchcock, 2001). The wildlife and other resources relative to the population in these relocation settlements were insufficient to permit these communities to sustain themselves, forcing them to become dependent on government welfare. The March 2000 Botswana government, “National Parks and Game Reserves Regulations”, indicated that residents in the CKGR at the time of its establishment could claim hunting rights but had to apply to the Director of Wildlife. This removed decentralized control over traditional hunting in the Central Kalahari and took away “special game licenses” for traditional hunting that in the past were issued by wildlife officers at the district level (Hitchcock, 2001; 2002b).

In November 2001, the Botswana government again forcibly removed the San and Bakgalagadi from the CKGR. Though groups like Survival International have tried to link De Beers to the expulsion of the Bushmen, leading anthropologists, (ANON, *pers. comm.*),⁴³ state that decisions for resettlement were taken as far back as 1986, and reiterated in 1988. The first removals were in 1997, with the balance of the removals in early 2001. Thus, this all took place before the big prospecting license allocation was granted. The instigator of this resettlement was the Ministry of Local Government, and not the Ministry of Mineral Resources and Water Affairs, nor the Ministry of Agriculture. The Department of Wildlife and

⁴³ Names withheld to protect them

National Parks in the Ministry of Commerce and Industry ultimately fought to have the people stay. Debswana (De Beers Botswana) came out and said that they did not want people to be removed, as did the headquarters of De Beers. Diamonds are not believed to be the major reason that the removals took place. If anyone is behind the removals, it is well-educated and rich Botswanans like two ministers who did not want the San, Bakgaladi, and their supporters (like the CKGR coalition and Survival International) telling them what to do. Their behavior was discriminatory and represented payback against opposition by 'uppity' San and Bakgalagadi, as well as organizations working with them that are believed to be at the center of the decision to remove people. In addition, there were those who actually believed that resettlement was key to development.

Colchester (2003) supports allegations by Survival International that most of the traditional Bushmen territory and the CKGR have been carved up into diamond prospecting leases to some of the world's largest mining companies with the support of the private sector arm of the World Bank, the International Finance Corporation and obviously the Botswana government. No names are provided.

In February 2002, another 450 people were loaded in trucks and moved to the resettlement villages of *New! Xade* and Caudate, resulting in less than 70 people left in the Central Kalahari Game Reserve (CKGR). The relocation camps were dysfunctional with few natural resources, and food handouts providing less than 1,700 calories per day (Kalahari Peoples Fund, 2002), less than the 1,840 calories/day minimum determined by the FAO (2000) as an indication of undernourishment. In the camps, the people faced public health/sanitation issues, loss of hunting rights, harassment and sexual assaults on young women (Kalahari Peoples Fund, 2002). Attempts in 2002 to take the matter of residential rights in the CKGR to court were dismissed on a technicality (Hitchcock, 2003c; Hitchcock, *et al.*, 2003). The case was appealed successfully, and now it is likely

that a new legal case will be heard in the High Court of Botswana in early 2004 (Hitchcock, *et al.*, 2003). There is concern that the failure of the San, despite support from human rights organizations and NGO's, to regain control over their land in the CKGR may set a precedent for the loss of land rights for all the San in Botswana (Kalahari Peoples Fund, 2002). In a landmark decision, Botswana's high court ruled December 13, 2006 that the so-called Bushmen of the Kalahari were illegally evicted from their ancestral land and should be allowed to return.

3.9.3 Eco-Genocide and Ik, the Mountain People

The Ik, numbering about 2,000 people, were a hunting and gathering tribe who moved between the border areas of Uganda, Kenya and Sudan (Turnbull, 1972).

In 1958, the Kidepo Game Reserve was proclaimed, covering 500 km² of the remote Karamoja region of (northeastern) Uganda (MacKenzie, 1997).

The Ik became confined to the mountainous area just east of the Kidepo National Park; formerly their major hunting grounds but because of colonial rules designed to preserve animals while humans, in consequence, starved and died. The area they were confined to, between the Kenya/Uganda border and Mount Morungole, had served as a temporary resting place during their nomadic movements, which were clear and precise depending on the time of the year, the rainfall/weather and the movement of game (Turnbull, 1972)

The Ik concept of family/kinship lent itself to the rapid and disastrous changes that took place following the restriction of their movement and hunting activities. The “family” simply ceased to exist. The Ik were forced to abandon hunting and become farmers on unproductive soils, and in trying to survive on a limited resource base lost the cooperativeness necessary for survival among hunter

gatherer cultures. Their mountain villages were far from inhabitable, the food was limited and unpalatable, and the people were unfriendly, uncharitable, and inhospitable. Those positive qualities that modern society values so highly were no longer functional for the Ik. This spelled ruin and disaster, as basic human qualities, which we take for granted in Western society, became superficial luxuries only affordable in times of plenty. There were no toilets in the villages. Society was in ruins and love ceased to exist. Religion was a thing of the past. Sharing was no longer a part of their social fabric, even between man and wife.

Poaching continued in Kidepo Park. A game kill was slaughtered and eaten on the spot in hopes that no one would discover the treasure before it was completely consumed. A person unable to fend for him/herself would die from starvation or disease.

Food was so scarce that three-year olds were thrown out of the hut and joined age groups as a means of survival. The Ik had been reduced to the behavior of a wild animal. For the species to have a chance of survival when good times might come, the population of breeding age must survive. Thus, children became expendable.

Stealing food became an acceptable part of the culture. Children delighted in beating the weak and the old, and stealing their food. Family and marriage as institutions and death as a celebration ceased to play a role in Ik Society. Young girls sold their bodies into prostitution for a bit of food. The Ik became welfare dependent, not wishing to make their meager fields too productive, even letting food rot in the field or be consumed by pests to avoid government/international famine relief from being cut off (Turnbull, 1972)

The destruction of the Ik and above cultures are but small examples that occurred throughout Sub-Saharan Africa, the New World and Australia, where European settlers brought their brand of conservation in which parks and game reserves became large zoos for the pleasure of the global and political elite, but to the disadvantage of the very people whose lives had been integrally linked with the wildlife on these reserves and parks, and whose lives would forever change in the “surgical” removal of these cultures from their ancestral grounds. The creation of Kidepo wiped out an entire civilization, that of the Ik, relegating them to the margins of humankind, turning them into beggars, thieves, prostitutes and malcontents.

Unfortunately, in 2003/4, there are strong indications that the creation of parks and protected areas is still occurring despite the unfavorable impacts on local cultures. The plight of the Baka Pygmies of Southeastern Cameroon will be discussed in Chapter 11 on foreign aid (Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and *Dobi Dobi*, More Parks and Protected Areas).

3.10 REMOVAL OF WILDLIFE AS AN IMPORTANT PROTEIN SOURCE IN AFRICAN DIET'S

Assuming the indigenous people primitive and uncultured, Major Hingston, reflecting the views of the

“white hunter-conservationists of the colonial time believed that ‘Meat is not part of the routine diet of the African native.’ Securing meat by hunting ‘is the stamp of primitiveness’ from which Europeans should lead him by teaching him ‘the meat-secur ing methods which are practiced by more cultured races.’ This would involve a ‘discouragement of native slaughter’ and ‘teaching of the keeping and breeding such as cattle, pigs, goats, sheep, fowl and ducks’ ” (JSPFE, 1930 In: MacKenzie, 1997).

MacKenzie (1997) contends that the destruction of game or its removal to remote game reserves, sometimes cleared of humans to make way for animals, and the denial of hunting rights to Africans had a significant effect not only on indigenous economic and social relations but also on nutrition. The elimination of game by European settlers, and restrictions on African hunting removed an important source of protein and a hedge against starvation. As one Southern Rhodesian, Jason Machiwanyika said in the early 1900s:

“ ‘Europeans took all guns from Africans and refused to let them shoot game. But Europeans shoot game. If an African shoots an animal with a gun, the African is arrested and the gun is confiscated’ ” (Machiwanyika n.d. *In: MacKenzie, 1997*).

In MacKenzie’s (1997) interviews with elderly Zimbabweans in 1973-74, they lamented on the following changes over the last 70 years: 1) land compression in creation of the communal areas and displacement of blacks for white settlement, 2) removal of trees, and 3) disappearance of game.

3.11 INCREASING HUMAN POPULATIONS, HABITAT DEGRADATION, HARD-EDGED PARKS AND PROTECTED AREAS

The introduction of modern medical and veterinary care, without concurrent birth control, resulted in a tremendous population growth rate in the 20th century, still continuing today (see Chapter 5 Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY). Along with land compression, this resulted in increasing land hunger resulting in the Kikuyu “Mau Mau” uprisings in Kenya beginning in 1948, to the politicized land hunger in Zimbabwe of 2000 (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and

wildlife). It also accelerated the degradation of Africa's natural systems, and resulted in the elimination of Africa's wildlife and its habitat over vast areas of the subcontinent. This continues to be a problem at the beginning of the 21st century, as a combination of human population growth and land compression from continual pressure by the West to expand parks and protected areas on the subcontinent is taking place. The process of creating parks and protected areas gives lip service to the needs of rural stakeholders, but with little concrete evidence of actualization on the ground (see Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers).

3.11.1 Population, Kikuyu and the Mau Mau

The problems with small farmers invading critical wildlife habitat around Amboseli and other areas in modern Kenya can be linked to the combination of land compression (European settlers taking land and creation of parks/protected areas), population increases and the introduction of unsustainable agricultural practices by the colonial masters: a problem that existed half a century ago (Hunter & Mannix, 1954; Dumont, 1966). At the beginning of the 21st century, this is a problem throughout much of Sub-Saharan Africa. For additional discussion see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya.

The Mau Mau uprising in 1948 by the Kikuyu was as much about land hunger as independence (Hunter & Mannix, 1954). By the late 1940s, Kenya's population consisted of five million Africans and 97,000 Asian immigrants dominated by 29,000 European settlers. The Kikuyu population had risen from greater than 1.25 million in the mid-1930s to an estimated 1.4 million Kikuyu by 1948 in the

Kiambu, Muranga, Nyeri, Meru and Embu Districts, as well as laborers on white settler farms in the Rift Valley. Official figures are that 12,000 Mau Mau died in combat, though actual figures may be greater than 20,000. From 1952-56, these districts became a police state. At the peak of the emergency more than 70,000 Kikuyu supporters were held in detention camps without trial, while over the entire period of this event at least 150,000 Kikuyu were held in detention camps and 1,090 hanged. Draconian anti-terrorist laws were introduced that suspended human rights, resulted in detention without trial and seizure of property, and imposed the death penalty for a wide range of offences (Anderson, 2005). To some degree, these actions are reminiscent of the United States reaction to the September 11, 2001 terrorist bombing of the World Trade Center.

Between 1903 and 1906 alone, white settlers occupied 24,291 ha (60,000 acres) of Kikuyu land. The most striking difference was the average size of the settler farm in 1905 of 2,227 ha (5,500 acres), while farms of the Kenyan Kikuyu elite were limited to 16.2 ha (40 acres) as a result of land expropriation (Hunter & Mannix, 1954). Population increases resulted in the area assigned to the Kikuyu as a reserve in some sections having 193 people/km² (500/mi²) by the late 1940s/early 1950s (Hunter & Mannix, 1954). For instance in Nyeri South the population had risen from 179 persons/km² (463/mi.²) in 1931 to 209 persons/km² (542/ mi.²) in 1944 with the average landholding decreasing from 3.27 to 2.72 ha (8.09 to 6.71 acres) over this period. By 1955 this figure had declined to 2.11 ha (5.22 acres)/landholding. By 1944, it was estimated that in order to have a decent quality of life, the number of families in South Nyeri would need to be reduced from 29,000 to 15,000, this being typical of the land pressures and compression across Kikuyu land (Anderson, 2005). One of the consequences was the formation of a labor market in the Kikuyu reserves, the settlers having vast amounts of land but little labor and the Africans possessing abundant labor but lacking land (Hunter & Mannix, 1954). This problem was “exacerbated when the process of

individualization of tenure in the reserves in the mid-1950s started with a deliberate aim of completely transforming African communal tenure relations into individualized land holdings" (Lumumba, 2005 *In: ACTS*, 2005). In addition to modern medical care, a key reason for this increase in population was believed to have been the loss of traditional family planning practices, requiring that a woman have no relations with her husband while nursing, a period of about two and one half years (Hunter & Mannix, 1954).

The Kikuyu felt robbed of their land. Therefore, a commission of enquiry was set up by the British, one member being the famous archeologist, Louis Leakey, who had grown up with the Kikuyu and had gone through Kikuyu manhood initiation rites. Misunderstandings existed, in that white settlers believed that they had bought land from the Kikuyu, but the Kikuyu considered that they were merely renting the land since, according to tribal law, no one could sell land without the consent of the clan. A second and third generation of white settlers was growing up on these farms and trying to dispossess the farmers would be utterly impractical - roughly equivalent to telling a third or fourth generation American farmer that his land belonged to the Indians. A previous commission had already given the Kikuyu 99,239 ha (245,120 acres) to compensate them for such errors. This was considered far more land than the Kikuyu's historical claim (Hunter & Mannix, 1954).

The Commission felt that still more land should be given to the Kikuyu. However, the population of Kenya had grown so swiftly that no new areas suitable for native farming were readily available. There were 100s of kilometers of semi-desert bush country, with so many boreholes sunk by colonists that the water table was dropping at an alarming rate and much of the groundwater had been found to be full of chemicals (e.g., assume sodium, potassium and magnesium salts – alkaline/high pH) that can rapidly result in soil salinization

(Hunter & Mannix, 1954) [see Chapter 5, Section 5.5.2, Physical and Environmental Constraints to Overcoming Food Production in Sub-Saharan Africa (SSA) and Section 5.5.2.3, Nutrients, pH, acidity and carrying capacity].

Compounding the population increase was the introduction by Europeans of unsustainable agricultural practices that once adopted, the Kikuyu refused to abandon. Before the coming of the whites, the Kikuyu had developed a system of traditional agriculture, rotating their crops, and preserving the soil and planting a number of different crops together (inter-cropping) so timed that one crop protected another. “Experts” from England explained that by separating the crops in different fields (mono-culture), the yield could be greatly increased. The natives tried it. The yield was indeed temporarily increased but heavy tropical rains washed away the topsoil. The experts realized their mistake and tried to induce the natives to return to their old system. The Kikuyu refused. They liked the high yield and had also begun to abandon their traditional crops in favor of new ones that were commercially more profitable but were also ruinous to the soil (Hunter & Mannix, 1954).

The commission concluded that the Kikuyu could not continue as a completely agricultural community. There was simply not enough suitable land to make it possible. Even if all of the Europeans left Kenya and their farms were turned over to the natives that would provide a solution for only a short time. The Europeans owned only about 20% (1/5th) of the land in Kenya and much of that was not suitable for the Kikuyu type of farming. At the rate the Kikuyu were increasing, the European farms would be little more than a “glass of water from a bucket” (Hunter & Mannix, 1954).

The commission felt that some attempt to find jobs for the Kikuyu - as artisans, tradesmen or in factories - should be made. Unfortunately, the enormous influx

of East Indians into the colony, many of whom were highly skilled artisans and tradesmen, made it difficult for the Kikuyu to compete in these fields (Hunter & Mannix, 1954).

The Swynnerton Plan of 1954 that encouraged small-scale Kikuyu farmers to engage in commercial agriculture was a political devise to counter the Mau Mau uprising that failed. The Kikuyu had already used the little understood compulsory terracing and other failed agricultural practices as a rallying point in the struggle against the colonial regime (Carswell, 2003 *In: Beinart & McGregor, 2003; Anderson, 2005*).

According to Parker (2005b) today

“there is little vacant land in traditional Kikuyu areas. When the land was originally broken down into privately owned parcels, there was a rule that further subdivision was not to be allowed and that one child would inherit the title, but pay out the others for what would have been their share on an even split between all. I don't think it worked and there are many properties now of less than 5 acres (<2 ha). The alternatives were for the surplus to move to towns and urban employment, or to buy land in other tribal areas. This pattern is common across the country with surplus population flowing out of the arable areas into the pastoral areas”.

In the 20th and 21st century this is resulting in major conflicts between the Maasai and Kikuyu throughout Kenya, as well as threatening critical wildlife habitat (Chapter 5, Section, 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya and Chapter 11, Section 11.11.9, Kenya Wildlife Service (KWS) – Living on Donor Handouts, Negative Impact on Kenya's Wildlife Outside Parks) (Figure 3.3).

Over much of Africa as a result of the 20th century population explosion, parks and protected areas became hard-edged [e.g., Lake Naivasha Park in Kenya, Kruger Park in South Africa, Lake Mburo in Uganda (see Chapter 11, Section 11.11.2, Donor Driven Conservation, Lake Mburo National Park (LMNP) and Benoué, Boubandjida and Faro Parks in Cameroon (see Chapter 5, Section 5.9.3.4, Over-population and livestock, a threat to wildlife in northern Cameroon)] surrounded by fences of human poverty and degradation, which to this day are slowly being encroached upon, having no obvious value to the hungry masses living in a day-to-day survival mode.

The current human population of Sub-Saharan has increased 5.5-6.5 times during the 20th century to about 622 million people and is projected to increase another 2.3-2.7x in the next 50 years (see Chapter 5, Table 5.12: Existing and projected populations in Africa and Sub-Saharan Africa). Likewise, the livestock population has increased 2.3x between 1961 and 2003 (see Chapter 6, Table 6.2: Livestock numbers Sub-Saharan Africa, 1961-2003) and will likely grow relative to the human population. One key question which must be addressed is can the tsetse fly and the “Wilds” of Sub-Saharan Africa survive this continual onslaught of humans and their livestock, even with what an ecologist might consider natural ecological controls such as disease, war and famine? Can giving wildlife value to rural communities partially solve the tendency for human populations to push aside nature in trying to survive [see Chapter 9, Community-Based Natural Resource Management (CBNRM)]? Or as in the Pre-1890s East Africa, will growing populations push back the bush, but instead of leaving open spaces for game as in the past, create a man-made landscape of farms and mega-cities, in which wildlife has neither value nor place?

3.12 COMPARISON WITH EUROPEAN COLONIZATION OF NORTH AMERICA

“The Great Spirit is our father, but earth is our mother. She nourishes us; that which we put into the ground she returns to us, and healing plants she gives us likewise. If we are wounded, we go to our mother and seek to lay the wounded part against her to be healed. Animals too do thus, they lay their wounds to the earth. When we go hunting, it is not our arrow that kills the moose however powerful be the bow; it is nature that kills him. The arrow sticks in his hide; and, like all living things, the moose goes to our mother to be healed. He seeks to lay his wound against the earth...” (Big Thunder of the Wabanakis Nation, Maine, circa 1900 *In: Kemf, 1993*)

With a common European heritage, the colonization of both North America and Sub-Saharan Africa had many similarities, but also huge differences. In much of North America, especially the USA, the Europeans eliminated the indigenous peoples, became a majority and established laws integrating all citizens into accessing natural resources as part of their management. In Sub-Saharan Africa, population numbers were reduced as a result of colonization, though local people remained a majority. However, their natural resources, especially wildlife, were made legally available mainly to the European minority that settled on the African subcontinent. As a result of this history, while in Sub-Saharan Africa an estimated 95% of wildlife and other resources are accessed clandestinely (e.g., illegally, poached), in North America only 5% are believed to be taken illegally, there being little need to poach.

3.12.1 Commonalities between the European Colonization of America and Africa

A comparison is made with the European colonization of North America to show the similarities in impacts on its indigenous people and wildlife. The exodus from Europe resulted from the continent having become over-populated, having limited

land space, suffering from poverty and exhibiting many of the phenomena we see in Africa today that caused habitat destruction, deterioration of a limited natural resource base and that offered limited economic opportunities to the majority. Thus, for many there was nothing to lose by heading to foreign exotic lands such as America, Canada, Africa, New Zealand and Australia. Historical novels by James Michener such as Chesapeake (Michener, 1978) and The Covenant (Michener, 1980) provide a perspective on this desperation. Life could not be worse than what had been experienced in Europe. As the saying on the Statue of Liberty goes, “Give me your tired, your poor, your huddled masses yearning to breathe free”. The European “*invasion*” of America left a lasting impact on the landscape, its people and wildlife, from which the indigenous people of the world’s only superpower in the 21st century have never recovered and never will. On both continents until the arrival of the European, the indigenous people lived in some sort of ebb and flow of balance between man-made and natural systems. The American Indian, since the mega-fauna extinctions of the Pleistocene (see Chapter 1, Section 1.3.2, Man and the Extinction of Pleistocene Mega-fauna), had reached a balance with those species that remained.

As in Sub-Saharan Africa, traditional management systems that successfully controlled and manipulated nature to the benefit of man were ignored and superseded by European systems and values. Wildlife was seen as a resource in such bounty that it would never end, and the average European settler in the USA, as in Africa, who had been cut off from using wildlife back home, slaughtered the game first to survive, but most importantly as an economic resource.

3.12.1.1 God-given duty to conquer nature

As in Africa, out of ignorance regarding the functioning of these ecosystems, interventions by European settlers resulted in a degree of environmental

degradation that the indigenous people had never known. As in Africa, Europeans settlers, believing it their God-given duty, changed the landscape into orderly geometric patterns of farms, pastures and woodlots. “They found a garden and left a wilderness” (Lowenthal, 1990 *In: Lowenthal, 1997 In: Griffiths & Robin, 1997*). From 1650 to 1850, in eastern America, 46 million ha of forest had been cleared for settlement and agriculture. Until 1885, America’s industry relied on forests as a cheap source of energy, without which it could not have become a world power. By the turn of the century (1900), 121.4 million ha of forest had been lost in America, after which forest reversion became more dominant than forest removal (Williams, 1997 *In: Griffiths & Robin, 1997*). Today, it is estimated in the eastern United States that only 25% of the forest remains, of which 0.1% [one tenth ($1/10^{\text{th}}$) of one percent (1%)] can be considered to be in the pristine state found by the pioneers (Guggisberg, 1970).

Four centuries were required for whites in North America to learn that the Indians’ traditional management of their wildlife was far more advanced than they were willing to admit. The West and African governments still fail, for the most part, to accept and recognize traditional knowledge by Africans over the management of their resources and fail to integrate this knowledge and ability into plans for the sustainable use of Sub-Saharan Africa’s natural resources. In Africa, “traditional knowledge” is a new and still controversial concept. In fact, most African governments are still at war with rural resource users!

3.12.1.2 Ignorance of traditional management systems by colonizers

Lacking metal harder than copper, and thus unable to fabricate modern axes, the Indians of the eastern forests practiced girdling (removing bark from trees) and setting fire to clear their land. As in Sub-Saharan Africa, the eastern tribes practiced “slash and burn” agriculture and periodically moved their villages once

the soils in a given area were worn out, thereby creating a fallow system. Wood ash and fish were used as fertilizers. The cleared areas immediately around the villages were cultivated and provided protection from surprise attacks. The secondary forest (e.g., abandoned fields) as in Sub-Saharan Africa, provided regrowth of vegetational species used to make baskets, spear shafts, lodge frames, etc., as well as providing wildlife habitat. Stone tools were used to cut the saplings of maple, birch and dogwood to make arrow shafts. These were species that grew not in climax but secondary forests recovering from being opened up by fire. Birch bark was used to make canoes. Blueberries, cranberries, grapes and other fruit grew wild along these edges between fields and forests. The increase in biodiversity between ecotomes is known as the “edge effect”, and provided excellent plant species diversity. Likewise, secondary forests also exhibited increased plant diversity and thus wildlife habitat compared to the beech-maple-oak climax forests found over much of the East. In comparison, climax forests have little undergrowth, poor plant species diversity, and provide poor habitat and low carrying capacity for game (Trefethen, 1975).

Early pilgrims noted the park-like environment around Indian settlements, which provided the grasses and browse needed by white-tailed deer, elk, and buffalo. White-tailed deer, bobwhite quail, cottontail rabbits, turkey and ruffed grouse abounded in and along these edges. Thus, the Woodland Indian, through manipulation of the forest contributed more to the production of wildlife than he extracted (Trefethen, 1975). Marks (1976; 2001) similarly, noted that until the end of the 1970s, when the commercial ivory and bushmeat trade took off, game was plentiful around villages in the Luangwa Valley of Zambia, most hunting taking place within 3 km of villages.

As in Africa, traditional ties to wildlife as a nutritional, cultural and spiritual resource were ignored. In many cases, by cutting the indigenous people off from

this resource, a key element to their survival was taken away; in the case of the buffalo (bison), the complete inability of the Plains Indian to survive without subsidized support. As in much of Africa, wildlife traditionally served as a hedge against drought and as a major source of protein.

3.12.1.3 Genocide, Indian reservations and land hunger by European immigrants

“Our roots are deep in the lands where we live. We have a great love for our country, for our birthplace is here. The soil is rich from the bones of thousands of our generations. Each of us was created in these lands and it is our duty to take great care of them, because from these lands will spring the future generations of our peoples. We walk bout with great respect, for the Earth is a very Sacred Place” (Sioux, Navajo and Iroquois Declaration, 1978 *In: Kemf, 1993*).

By 1830, demand for land in the eastern USA was so great, as a result of both misuse and new European immigrants, that Congress passed the Indian Removal Act dispossessing the remaining Indian tribes of their land. This resulted in what some call the “Trail of Tears” as the Creeks, Cherokees, Chickasaws and Seminoles of the East were marched to “Indian reservations” in Oklahoma. Interestingly enough, a number of Creole-speaking Gullah fought alongside the Seminole Indians against the U.S. Government. The Gullah are ex-slaves who escaped early on in American history to the barrier islands from the Carolinas to Florida and who speak a language which is a mixture of English and those languages from the Gulf of Guinea (e.g. Sierra Leone, Ghana, Benin, Togo to northern Angola). Many Gullah were rounded up and became part of the “Trail of Tears” march, resulting in the establishment of Gullah-speaking communities in the modern state of Oklahoma. Thousands died along the way of the “long march” to their new and sterile homelands (Trefethen, 1975). Indians were placed on reservations to make way for white settlers, similar to the creation of

homelands and communal areas in East and Southern Africa. Similarly, the Indians ended up on the poorest agricultural lands, condemned to poverty, with the exception of where minerals or oil existed that the U.S. Government was unaware of. Many were and are still unable to survive without government handouts. Often, escaping meant/means leaving the reservation and abandoning what little was/is left of their culture to join the “White Man’s World”, or hiding behind a bottle of alcohol and drugs as one sees with the San of Southern Africa and the Baka Pygmies of Southeastern Cameroon.

This same land hunger by European settlers living in an over-populated and increasingly degraded eastern United States would soon spawn the “westward ho” movement of covered wagons to the western United States, with similar consequences for both the Indians and wildlife. In the “Wild West” Indians were hunted down like vermin, exposed to diseases for which they had no immunity (small pox, typhus, measles, influenza, bubonic plague, diphtheria, mumps, scarlet fever, whooping cough and syphilis), which had been brought in by the Europeans (Lewy, 2004), and had much of the wildlife plundered, on which their lives and traditions depended. “Decreased birth rates resulting from oppression and disruption of ways-of-life also had an impact” on American Indian populations (Wikipedia, 2005). Estimates of the American Indian population of North America vary from a high of 18 million (10 million in the USA) to a low of 1,152,950 before the coming of the European. By the end of the 19th century, in the United States only 250,000 Native Americans remained alive (Lewy, 2004). The question of explicit genocide such as providing small pox infected blankets is emotive and highly debated (Lewy, 2004; Brown, 2005; d’Errico, 2005; TheFurTrapper, 2005; Wikipedia, 2005). Today in North America, the once mighty Indian nations are a shadow of their former selves, surviving on the periphery of white man’s land that has been carved from their once bountiful territories.

3.12.1.4 Wildlife as a tool of conquest in North America

On both continents, the European invader saw wildlife as a tool for the exploration, expansion of white control and “development” of the country. Hunting and trapping, as in Africa, was a key ingredient in the European imperial conquest and development of North America, without which it might not have been “colonized and developed” (from a Western perspective) as quickly. As in Africa, in the first few years, until agriculture and livestock could be established, the frontiersman lived off the land, eating venison and waterfowl, and trapping beavers and other animals, whose furs they used for sale and barter.

For example, market hunters were contracted to bring more than three tons of game/week to Leadville, Montana’s mining camps, butcher shops and restaurants; a single hunter’s kill for the week of August 11-18, 1878 was 24 deer, 22 antelope, nine elk, five bighorn sheep and one grizzly (Rennicke, 1990). As in Sub-Saharan Africa, many species were greatly reduced or pushed to extinction from over-hunting by European settlers:

- **Auk.** As the European’s headed towards North America, one of the first species to go in 1840 was the flightless Auk, *Pinguinus impennis* (Trefethen, 1975), found on the rocky islands and coasts of the North Atlantic in Canada, Greenland, Iceland, the British Isles and Scandinavia (CMN, 2005). It was clubbed to extinction by European fishermen (Trefethen, 1975).
- **Eastern Elk and Wood Bison.** By the 1800s, the eastern elk, *Cervus canadensis canadensis*, and wood bison, *Bison bison athabascae* had succumbed to the human avalanche and domestic livestock (Trefethen, 1975).

- **Beaver.** By the 1830s, the beaver, *Castor canadensis*, was on its way to extinction in the Mississippi Valley. Further west a new breed of “mountain men” developed, trapping out the last of the beaver. The collapse of the beaver trade in 1831, as a result of silk now being preferred for men’s hats, came just in time to save this species from extinction (Trefethen, 1975).
- **Passenger Pigeon.** The last great nesting colony of passenger pigeons, *Ectopistes migratorius*, was discovered near Petoskey, Michigan in 1878. In a few weeks, 2,500 netters marketed 1,107,800,066 pigeons. The end of the passenger pigeon as a viable species occurred in 1881, when Grand Traverse County, Michigan netted 1 million birds. While market hunters helped finish off the passenger pigeon, the last known survivor dying in the Cincinnati Zoological Gardens on September 1, 1914, the real determining factor was “habitat loss” as settlers destroyed the virgin forests that passenger pigeons required for both food and nesting sites so that by the 1900s there was no place that could support such masses of bird life (Trefethen, 1975).
- **Heath Hen.** The heath hen, *Tympanuchus cupido cupido*, once ranged from Maine to Virginia but a combination of habitat destruction by expanding human populations and over-hunting resulted in it being confined almost entirely to the island of Martha’s Vineyard off Cape Cod, Massachusetts (Trefethen, 1975; Leakey & Lewin, 1995) by 1850 (Trefethen, 1975). A series of events, ranging from fires, introduction of the western race of “prairie chicken”, *Tympanuchus cupido pinnatus*, (resulting in possible interbreeding), the presence of local predators (fox, raccoons, skunks and in an influx of goshawks), the introduction of dogs

and cats, and blackhead disease introduced by turkey farming led to uneven sex ratios with males greatly exceeding females. This adversely impacted breeding and nesting success, and resulted in the population going from a high of 2,000 in 1916 to 50 by 1926. In 1930, one lone male was observed carrying out its ritual mating dance; he was seen again in 1932 for the last time. By 1925, the State of Massachusetts had spent US\$ 56,912 in the nation's first attempt to save an endangered bird; the attempt failed. In its original range of many thousands of km², the heath hen was virtually immune to extinction. Reduced to a tiny single population, it became vulnerable both to the vagaries of nature and to man related interventions (Trefethen, 1975).

- **White-Tailed Deer.** A long open season without bag limit and the continued loss of habitat by the ever-expanding European immigrants resulted in white-tailed deer, *Odocoileus virginianus*, being nearly wiped out by the time of the Revolutionary War in the mid-1700s (Trefethen, 1975).
- **Plains Buffalo.** Plains buffalo, *Bison bison*, at one time numbering 75 million, was a commodity used by explorers, settlers, trappers and rail lines in opening up the West. Knowing that elimination of the buffalo would subdue the plains Indians, who depended on buffalo for food, housing (tepee), clothing and utensils, in 1874, President Ulysses S. Grant, on advice of General William Tecumseh Sherman, pocket vetoed a bill passed by Congress to “ ‘prevent the useless slaughter of the buffaloes within the Territories of the United States’ ” (Trefethen, 1975). The most brutal and wasteful chapter in the history of America’s wildlife was that within a decade, from about 1871 – 1881, these massive herds, numbering in the millions, were virtually eliminated (Trefethen, 1975). As Sherman

said, “ ‘Every buffalo dead is an Indian gone’ ” (Guggisberg, 1970). In 2004, there were about 16,000 buffalo left in the wild, with the only remaining free-ranging herd of 3,800 in Yellowstone National Park. However, about 231,950 plains buffalo are raised commercially on 4,132 ranches across the United States (Eilperin, 2004).

Further evidence of the destruction that existed by the end of the 19th century is contained in Table 3.2.

3.12.1.5 Introduction of exotic species

As in Africa, European-introduced domestic livestock brought in disease and competed with wildlife for food and space. Exotic trees had similar impacts on native vegetation. By the beginning of the 20th century, both the wildlife and wildlife habitat were in a bad state. As in Sub-Saharan Africa, a conservation ethic towards wildlife did not develop until after the conquest of the continent by the Europeans (Trefethen, 1975).

3.12.1.6 Parks and reserves after the conquest

The creation of parks and protected areas, separating humans from nature, while allowing them to visit it on weekends, was only started after wildlife populations had been decimated and white settlers had taken control of North America by force. America was also beginning to industrialize, creating a *nouveau riche* class out of which emerged the 19th century sports hunter. In 1844, the New York Sportsman’s Club was formed for the protection and preservation of game. It helped draft model game laws with seasons for woodcock, grouse, deer and trout. Federal (central) government took little interest in conservation through the 1800s

with no federal laws to protect wild birds, mammals or fish and no enforcement agency; national parks were still being protected by the U.S. Army.

Table 3.2: Over-exploitation of wildlife and its habitat in pre-industrialized America and its recovery in the 20th century from conservation efforts – mainly by hunter-conservationists

SPECIES	DATE/TOTAL NUMBER IN USA	TOTAL NUMBER IN 2001
White-Tailed Deer ¹ <i>Odocoileus virginianus</i>	1900 < 500,000 1985 <55 million	36 million ¹ 105 million ²
Duck ²		
Rocky Mountain Elk ³ “Wapiti” <i>Cervus canadensis</i>	1907 <41,000	1.2 million ³
North American Wild Sheep ⁴ <i>Ovis canadensis</i> ssp.	1900s <10,000	230,000 ⁴
Wild Turkey ⁵ <i>Meleagris gallopavo</i> ssp.	1890s <30,000	6.4 million ⁵
Pronghorn Antelope ⁶ <i>Antilocapra americana</i>	1910 <15,000	1 million ⁶
Black Bear ⁷ <i>Ursus americanus</i>	1900 – Unknown but numbers significantly reduced	1 million ⁷
North American Moose ⁷ <i>Alces americana</i>	1937 <14,000	1.2 million ⁸

On March 1, 1872, President (General) Ulysses S. Grant signed into law a congressional bill creating the first American Park, Yellowstone, encompassing an area of 8,671 km² (3,348 mi.²) area (Trefethen, 1975). Yellowstone was established on Crow, Blackfeet and Shoshone-Bannock Indians' territory. A subtribe of the Shoshone lived year-round within the present bounds of the park, while the other tribes used the area seasonally for hunting and fishing. Indians had lived in this park for at least 800 years. As was the case with the creation of African parks and protected areas, they did not leave willingly. In the summer of 1877, 300 people were killed in a conflict between tribal groups and civilian officials. By 1886, administration of the park was turned over to the U.S. Army (Kemf, 1993).

The main impetus for establishing this park was to save one of the last remaining buffalo herds. After seeing the slaughter of big game in the western USA, Teddy Roosevelt, often known as the “father of America’s national parks”, and also an avid hunter, founded the Boone and Crockett Club with other hunters in 1887 to fight for the sustainable use of big game in North America. He later became America’s 26th President. This was followed by the creation of Sequoia, General Grant and Yosemite National Parks (Trefethen, 1975). Yellowstone became the model for all future parks. It was an exclusion zone separating people from wildlife, in which there was little or no active management of the resources, allowing “nature” to take its course, but without one of the key components of nature involved – man! Although the first model for national parks began in America, Vande weghe (2004) argues that the concept germinated in the Cape region of South Africa around 1850 by Ludwig Pappe, an Austrian surgeon, concerned over the rate of deforestation. This led to the first forest law of 1846 and then the Forest and Herbage Preservation Act in 1858 that helped in the establishment of the first faunal reserves. Pappe’s successor as botanist-in-chief of the colony, John Brown, eventually returned to Scotland where he continued to

write on forest and water conservation. His writings eventually made their way to North America, which influenced the publication of *Man and Nature* in 1864 by G.P. Marsh. Ideas emanating from this publication became the basis for creation of Yellowstone National Park. This idea would then come full circle with the establishment of the first national park in Africa, Albert in 1925.

Though a bit late in coming, as in Sub-Saharan Africa, the eventual recovery of wildlife in the United States started early in the 20th century. Conservation actions were taken by sport hunters, who eventually developed organizations, as noted above (Table 3.2), that are dedicated to the enhancement of particular game species and their habitat, and who worked hand in hand with state fish and game departments to build up these populations, while hunting them for recreational, cultural and subsistence purposes. In contrast, in Sub-Saharan Africa, resource users and wildlife/parks departments to date have generally failed to find common grounds on which to collaborate in the conservation of natural resources. Being in a relationship of conflict, in most cases Sub-Saharan Africa's parks and protected areas served/serve more the interests of Western tourists/hunters and NGOs than those of Africans (see Chapter 9 on Community-Based Natural Resource Management and Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers).

Eastern White-Tailed Deer's Remarkable Recovery

The white-tailed deer had its habitat usurped by cattle, sheep and goats, and was hunted excessively for its flesh and hides. It was soon eliminated from the colonial coastal settlements and river valleys. Logging that created secondary habitat resulted in deer populations increasing compared to populations in virgin forests where there numbers had been very low.

The first game legislation in the USA was to protect the white-tailed deer with a closed season from spring to fall of each year. However, the long open season, without bag limit and the continued loss of habitat by the ever-expanding European immigrant population resulted in white-tailed deer being nearly wiped out by the time of the Revolutionary War in the mid-1700s. These colonial laws, as in Sub-Saharan Africa, were initially ineffective, but did establish a basic foundation for the protection and management of wildlife (Trefethen, 1975).

White-tailed deer reached a low point in numbers between 1870 and 1900 (Trefethen, 1975) because of the killing of deer for profit (Miller, 2002), as well as habitat loss. The Lacey Act of 1900, which assisted in ending market hunting, helped to save the white-tailed deer (Miller, 2002). Black bear and turkey had been reduced to even lower levels. Only in the West did one find “big game” animals in significant numbers (Trefethen, 1975), and even their numbers were not at a peak high (Table 3.2).

The proper name for this deer is the “Virginia white-tailed deer”. In Virginia, it had been just about wiped out. By 1931, recovery was slow, as there were only 25,000 deer left in the entire State of Virginia; less than $0.8/\text{km}^2$ ($2/\text{mi}^2$) (Miller, 2002). In the first part of the century, there were enough white-tailed deer to allow the walls of the hunting and fishing cabin of Lancelot Jacques,⁴⁴ on Little Hunting Creek in the Catoctin Mountains of Maryland, to be adorned with deer antlers, even a monster 16 point eastern count trophy. By the time, the principal author was old enough to hunt in the early 1960s one had to be lucky to see a white-tailed deer, let alone shoot one in the State of Maryland. Hunting was more of a ritual, with little hope of gaining meat or a trophy.

⁴⁴ The primary author’s grandfather of Huguenot descent similar to many South Africans.

By 2002, the white-tailed deer populations in these states had recovered. There were an estimated 1.25 million white-tailed deer in the states of Maryland (250,000) and Virginia (1 million). There were more deer than when the first colony in America, Jamestown, Virginia, was established in 1607, when the deer population in the two states was estimated to be only 500,000 in number (Miller, 2002).

Thus, it took almost 1.5 – 2 generations for the deer populations to recover and then explode to the point where they are actually a pest, getting into people's gardens and causing major road accidents (Miller, 2002). Nation-wide, it is estimated that annually white-tailed deer result in 1.5 million traffic accidents resulting in US\$ 1.1 billion damage and 150 deaths (Ashton, 2003; CNN/Money, 2005). The incredible success story of the white-tailed deer recovery is attributed to reforestation, farms being abandoned (going back into secondary forests) and restocking (Miller, 2002). Initially strictly enforced game laws were put into place such as shooting only forked-horn bucks (two-year olds) or older males in order to retain does for breeding to build up the population.

The trap and transfer method as a means of regulating deer populations costs US\$ 800/deer and is too expensive, just as is the case with elephants in Sub-Saharan Africa. As in Sub-Saharan Africa, it is a temporary fix, as the number of new places (available habitat) to transfer deer is limited by there being too many deer everywhere. Reintroducing bobcats and wolves as natural deer predators is too dangerous given the number of people living in and around the deer, and an unproven method. Deer birth control has also proven controversial, as with African elephant whose populations are in need of control. "Contraception alone cannot reduce overabundant deer populations to healthy levels...to be used in conjunction with other wildlife management methods", and cannot eliminate the

need for hunting (USDA/APHIS, 2005), even if they eventually would prove effective to some degree.

Allowing hunters to shoot and kill deer is considered the easiest and least expensive method to reduce the population. In Maryland in 1996, more than 100 deer were killed by cars around Seneca Creek State Park near Gaithersburg, Maryland, while after allowing sport hunters to thin the herd, only 50 automobile accidents happened. In this case, the fish and game department used hunting as a major management tool to protect both habitat and people (Miller, 2002).

By the mid-1990s in Virginia and Maryland, the East in general, the deer population had become so large that it became necessary to thin the herds by significantly reducing the number of reproductively active females. In herding animals, one male can service many females. Some states, such as Virginia, allow a hunter, to continue hunting on his/her license as long as female deer are harvested. As soon as a buck is harvested, the season is over, or as in Maryland, two females must be killed before another buck can be taken. This provides a stark contrast to the 1960s when one was lucky to see a deer. In 2001, of the 83,787 deer killed in Maryland, 50% were female (Miller, 2002)

White-tailed deer have also adapted well to the “edge effect” created by backyards and parks in urban America. Suburbia provides deer with an Eden of trees, shrubs, gardens and flowers in which they can flourish. In 2002, there were so many deer living in amongst the homes and community forests/green belts in suburbia that the Virginia Department of Game and Inland Fisheries could not meet its yearly deer reduction quota necessary to maintain habitat quality (e.g., prevent over-browsing by deer).

Fairfax County, Virginia, and Minneapolis St. Paul, Minnesota have developed urban deer hunting programs allowing the use of bow and arrow as a means of deer reduction in suburbia. Hunters literally hunt between homes and back yards. The bow and arrow is the weapon of choice as; rifle hunting in such crowded areas is too dangerous.

The situation became so bad that in 2002 that a buck ran amuck through a supermarket in Blacksburg, Virginia (home of the Virginia Polytechnique Institute – VPI) and in the U.S.’s capital two bucks jumped through the window of a MacDonald’s hamburger franchise in northeast Washington, D.C. In 2001, there were 4,229 automobile crashes between vehicles and deer in Maryland and 6,030 in Virginia. The estimated damage was US\$ 50 million in damage (Miller, 2002).

In Maryland, the dwindling numbers of hunters are considered the biggest obstacle to controlling deer populations. Ironically, too many young people, who a generation ago would have been deer hunting, even though there weren’t any, are content to stay home, watch TV and play video games; the number of licensed hunters in Maryland declining from 180,000 to 140,000 since 1970; the number of young hunters under 16 years of age dropping from 23,000 in the 1970s to 7,000 in the early 1990s. Junior hunter programs by the state have brought the number of youths up to 9,600 in recent times, which is believed to be a key to controlling deer populations in the future, “Suburban deer are going to be on the radar for a long time. It’s going to be an issue in this state forever”, says a Maryland game official (Miller, 2002).

Certainly, throughout its range in the USA, the Virginia white-tailed deer recovery can be considered an over-whelming success; some say too successful.

Maybe one of the most important lessons to be learned and contrasts to be seen, when comparing the U.S. to Sub-Saharan Africa, is that in Africa wildlife is mostly found in parks and protected areas, and/or on private mostly white-owned ranches and enclosed game ranches. No buck would ever have a chance of making it to suburbia in most of Sub-Saharan Africa, as it would be eaten along the way. It was not that long ago that the same situation existed in America. In many states, schools were closed on the opening day of hunting season since most young boys would be in the field with their fathers hunting game as a food supplement. In America, going through an urbanization and industrialization process and taking the people away from a direct dependency on nature helped take pressure off the wildlife and the habitat. This also gave people the luxury to develop a conservation ethic and awoke an interest in buying into conservation and wildlife recovery programs (quotas, seasons, reintroduction programs and habitat recovery programs) and ultimately allowed the habitat and wildlife to start recovering. In addition to devolution (land and resource tenure – See Chapter 9), this provides a hint of the direction that Sub-Saharan Africa may have to consider taking in the 21st century, if wildlife and its natural systems are to survive the onslaught of humanity.

On the downside, in the urbanized West, a small but vocal percentage of the population is so isolated from wildlife that they fail to understand the need for its management and the strong cultural ties of the hunt to society. These “animal rightists”, as they call themselves, virtually worship wildlife, being against its sustainable use.

3.12.1.7 Park-preservation policies

In America, settlers hunted in national parks until 1894, when legislation prohibited multiple use (MacKenzie, 1997), turning them into areas of preservation where a “natural regulation” policy tended to exist. As in Africa, this meant complete protection and no active management or manipulation of the systems. This resulted in no burn policies, among others. Not until the 1990s did ecologists begin to view fire as part of the natural cycle in many ecosystems, especially in western USA. The build up of biomass, which was not natural, resulted in extremely hot fires, also not natural. These hot fires had a major impact on vegetation and in turn game populations as documented in Yellowstone and Rocky Mountain National Parks (Hess, 1994).

Whereas indigenous and pioneering settler populations lived in nature and exploited it, the national parks were meant to be a corrective to industrialization and urbanization. They were meant to show increasingly urban societies (beginning in the USA and eventually urbanized industrialized South Africa with the establishment of the Kruger National Park) of the 20th century what nature had been like before human influence. They were to be a powerful civilizing influence that would remove “the hunting instinct”, the “best weapon whereby Man’s impulse to destroy the beasts of the forest for his own pleasure and profit can be fought and conquered’ ” (Stevenson-Hamilton, 1940 *In:* MacKenzie, 1997).

3.12.2 Sustainable-Use in Forest Reserves

President and hunter conservationist Teddy Roosevelt, with the help of Gifford Pinchot, the “father of modern forestry management” in America, focused on national forest reserves, which by 1896 had expanded to 8,615,320 ha

(21,279,840 acres) as centers of conservation through sustainable use (e.g., hunting, fishing, grazing and logging) (Trefethen, 1975). Forest reserves were often bordering parks, which would stock the reserves for the “hunting elite”. Parks and forest reserves represented a demarcated land use between human cultivators and fauna (MacKenzie, 1997). Similar concepts existed in Africa, where for example hunting blocks in the Luangwa Valley, Zambia or the savanna hunting blocks of Cameroon surrounded core parks that fed/feed game into these areas, while the hunting blocks both buffered/buffer the parks from human interference and served/serve as important income generators.

3.12.3 Beginning of the Green Movement

In 1892, the well-known preservationist John Muir formed the Sierra Club. Here was the beginning of a dichotomy and an ideological battlefield between groups like the Sierra Club, the beginning of the “green movement”, which philosophically believed in the full protection of natural areas, and other groups such as Boone and Crockett that believed in regulated use or “management”. The word “Conservation” as applied to natural resources did not come into the English language until 1907 put forth by Gifford Pinchot to describe the interrelationship and sustained-yield use of forests, soils, waters, fish, wildlife, minerals and other natural resources (e.g., in Africa game reserves and hunting blocks; in America state and federal forests, Bureau of Land Management land). “Protection” and “Preservation”, then in common use, meant non-use – a locking up of the resources (e.g., creation of national parks), a concept that grated on Pinchot’s practical sensibilities (Trefethen, 1975). Many professionals and laymen on both continents misuse the word “conservation” when talking of parks. Even hunters fail to associate their actions with the word “conservation”. As in Africa, government at both the state and federal level took more and more responsibility

for managing America's wildlife, fish, trees, and public grazing areas (Trefethen, 1975).

3.12.4 Land and Resource Tenure

One big difference between many small-scale rural societies in Africa and America is that the American Indian's own their own lands and their "reservations" are considered "nations" within a nation. In Sub-Saharan Africa, other than on a small amount of white-owned and even smaller amount of black-owned commercial farms, mostly in Southern Africa and Kenya, the majority of land and associated natural resources are owned by the state. As is discussed in Chapter 9, Section 9.9, WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM, it required a lawsuit that went all the way to the Supreme Court of the United States for American Indians to start getting their wildlife back. Where this has occurred, wildlife tends to integrate the socio-cultural values of Indians into the management of wildlife and other resources, as well as serving as an economic resource for the community. At independence, Sub-Saharan African states tended to nationalize all land and valuable resources, including wildlife. In Sub-Saharan Africa, these battles have yet to be fought; land and resource tenure being a major hurdle to true democracy (see Chapter 11, Section 11.6, AFRICAN DEMOCRACY IN THE 20 and 21ST CENTURIES). Many Kenyans communally own their land (see Chapter 5, Section, 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya), and today are fighting to get their wildlife back (see Chapter 11, Section, 11.11.9, Kenya Wildlife Service (KWS) – Living on Donor Handouts, Negative Impact on Kenya's Wildlife Outside Parks).

3.12.5 Differences between the European Colonization of America and Africa

As discussed, the Indian numbers were reduced and subdued by Europeans through genocide and the introduction of diseases, against which the Indian had no immunity (e.g., small pox) (see Section, 3.12.1.3, Genocide, Indian reservations and land hunger by European immigrants) to about 250,000 by the end of the 19th century. Thus, their populations never became dominant as opposed to the Sub-Saharan African's whose number increased about 5.5-6.5 times in the 20th century, in many instances placing them out of balance with their surroundings (see Section 3.1.7.2, Cultural genocide and Chapter 5, Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY).

Urbanization and industrialization in 20th century North America gave people wealth, and removed them from the day-to-day dependence of surviving on and so closely depending on nature. Therefore, they could afford the luxury of developing a modern “conservation ethic”, which if one is honest reflects the traditional conservation mores of the American Indians and rural Africans who respected nature and attempted to live in some sort of balance with it. By contrast, even in 21st century Sub-Saharan Africa current game, fish and forestry laws disenfranchise Africans on an over-populated and under-developed continent so closely tied to and dependent on nature for day-to-day survival. Thus, with few exceptions (e.g., industrialized and urbanized South Africa), a subsistence lifestyle does not permit the luxury of developing a conservation ethic in a Western sense (e.g., biodiversity conservation, sustainable use, etc.). Meanwhile Africans’ traditional conservation ethic of sustainable use tied to the ancestors and spirit world as with the American Indian, has been highly eroded and/or eliminated due to colonialism and the last 40 years of independence – for the most

part a continuation of colonial laws – that have legally separated them from their resources and forced them into short-term relationships with wildlife and other resources over which they have little or no control. This centralized

“approach was bolstered in the post-colonial era by a belief in state direction of the economy; in governments as major employers; and in political ideologies favoring public ownership and control of potentially productive resources” (Roe, *et al.*, 2000).

National parks (preservationist areas as in both America and Sub-Saharan Africa), national forests and state parks (multiple use areas as are many game reserves and hunting blocks in Sub-Saharan Africa) were made affordable and available to all Americans regardless of race, creed, color or political affiliation (Table 3.3), whereas in Sub-Saharan Africa, 99% of the people are cut off from and cannot afford the luxury of taking advantage of these natural systems.

In America the management of wildlife, except migratory species (mostly dove, ducks and geese) is mostly delegated/decentralized to the State as opposed to the Federal Government, whereas in most of Sub-Saharan Africa control is vested in central government, an exception being South Africa with provincial control of all hunted species. In America, wildlife and other natural resources became “Common Property Resources” managed by government “for the people”, often in co-management relationships with sportsmen. Up until recently, the majority have been of European decent, though this is rapidly changing with globalization. In North America, public land, other than national parks, tends to be managed for the multiple use of resources available and affordable to the public, from petrol station attendants to medical doctors. Meanwhile in Sub-Saharan Africa governments managed and continue to manage wildlife and public land “against the people”, in the interests first of “a European settler elite” and today for “an overseas white elite” mostly from America and Europe.

Table 3.3: The majority of U.S federal and state lands permit multiple use of resources by citizens

USA SURFACE AREA (1)	9,826,630 km ² (3,794,083 mi. ²) or 9.8 x 10 ⁸ ha or 24 acres x 10 ⁸	
FEDERAL PROTECTED AREAS: Hectares (Acres)		
National Forests	77.3 million (191 million) (2)	Allows Multiple Use Of Resources
Bureau Of Land Management	77.7 million (192 million) (3)	Yes (hunting, fishing, logging, some grazing)
National Park System	107 million (264 million) (2) (3)	Yes (hunting, fishing, grazing)
National Wildlife Register	33 million(82 million) (2) 34 million (84 million) (3)	Yes (fishing)
Total Federal Protected Areas	38.1 million (94 million) (3) 217.3 million (537 million) (2) to 256.8 million (634 million) (3)	Yes, (hunting and fishing priority uses) Total Multiple Use: 217.3 million (537 million) (2) to 256.8 million (634 million) (3)
STATE SYSTEM OF PROTECTED AREAS: Hectares (Acres)		
Wildlife Management Areas (WMAs)	20.2 million (50 million) (3)	Allows Multiple Use Of Resources
State Parks	3,174,863 (7,841,914) (3) (4)	Yes (hunting and fishing)
Recreational Areas	516,978 (1,276,910) (3) (4)	?
Natural Areas	416,096 (1,027,756) (3) (4)	?
Historical Areas	31,892 (78,774) (3) (4)	?
Environmental Education Areas	38,269 (94,525) (3) (4)	?
Scientific Areas	4,463 (11,024) (3) (4)	?
Forest Areas	311,774 (770,082) (3) (4)	Yes (hunting, fishing, logging)
Other	58,630 (144,816) (3) (4)	?
Fish and Wildlife Areas	166,037 (410,112) (3) (4)	Yes (hunting and fishing)
Miscellaneous Areas	87,734 (216,703) (3) (4)	?
Total State Areas	4.8 million (11.8 million) (4) to 25 million (61.8 million) (3)	Total Multiple Use: 3.7 million (8.8 million) to 23.8 million (58.8 million) (3)
Grand Total Federal And State Protected Areas	222 million (549 million) (2) (4) to 282 million (696 million) (3)	221 million (546 million) (2)(4) to 281 million (694 million)
Percentage of Total Protected Areas Allowing Multiple Use		99.6%
Percentage Total Land Area	22.7% (2) + (4) to 28.8% (3)

Thus, over most of Africa, wildlife and other resources became and remain “Open Access Resources” legally not accessible by the majority of the citizens, which forces them to become “poachers” of wildlife, fish, forests, pasture, etc. Africans see caretakers of natural resources (e.g., game wardens and guards, forest guards, park wardens/guards, fish wardens) as the enemy who is keeping them from the resources they need for survival. In contrast, 95% of the resources in North America are legally harvested in the interests of its citizens, who collaborate with the game wardens, while in Sub-Saharan Africa 95% of the resources are poached making sustainable management impossible since the responsible management bodies have become “enemies of the people”.

3.12.5.1 Development of an anti-market hunting wildlife culture in America

From the above, it can be ascertained that habitat loss (e.g., of the passenger pigeon, eastern elk and wood bison) along with expansionist strategies of the newly emerging and rapidly growing American nation (e.g., elimination of the buffalo) played key roles in the extinction and/or significant reduction of these species on the North American continent. As a result, due to the perceived adverse impacts of commercial market hunting on wildlife, the American public developed a “wildlife culture” in the United States that is anti-commercial use (Thomson, 2003). While America allows hunting for both cultural and non-commercial purposes, this is based on a limited offtake, and with few exceptions depending upon the state (e.g., paying processing fees for game meat donated to the hungry/poor, fundraisers by not-for-profit sportsmen’s groups, American Indians to each other) the meat from free ranging wildlife cannot be sold for profit. Selling of other game parts is highly regulated (ODFW, 2004; PGC, 2004; State of Texas, 2006; TWRA, 2006; DGIF, 2007). Until recently, the only game meat one would find in an American restaurant would be exotic game that comes from high fenced ranches, mostly in Texas. Since the early 1990s, game ranching

of indigenous elk, deer and bison is growing in the USA to meet the demand for trophy hunting, meat, leather and elk antler velvet for the Asian medicinal market. The North American Deer Farmers Association members in the USA and Canada own over 385,000 cervid livestock of which indigenous species of elk and white-tail deer make up 26.9% and 4.6% of the population respectively, the rest being exotics (NADEFA, 2007). The “inability of native white-tailed deer to utilize warm-season perennial grasses does not allow them to be farmed as readily as the introduced deer species and elk” (Evers, 2006). By 2000, the USA had 1,200 elk ranches with over 70,000 elk. Chronic wasting disease (CWD) has adversely impacted both domestic and international markets for elk (Hansen, 2006) and deer (APHIS, 2002). There are an estimated 500,000 bison in North America of which 95% are on about 4000 private farms or ranches (NABSG, 2006). Of this, there are about 150,000 bison in the USA, of which 20,000 are slaughtered/year compared to 125,000 cattle/day (USDA, 2003). Even with these advances, the sale of game meat in restaurants and supermarkets, as well as game derived curios is relatively uncommon in America compared to Southern Africa.

This conflict of “wildlife cultures” manifest in how America perceives wildlife, is seen throughout this evaluation but comes out most strongly in how an industrialized and urbanized United States, which dominates the Convention on International Trade in Endangered Species (CITES), relates to rural resource based Sub-Saharan Africa with regard to the latter’s desire to commercially market its wildlife, especially elephant and rhino byproducts, but also other species (see Chapter 10). It is also seen in the imposition of Western urban values towards wild areas, in the continual disenfranchisement of rural Africans from their natural systems in the 21st century with Western money channeled through Western NGOs (see Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers).

3.13 CONCLUSIONS

As seen from previous chapters, it can be concluded that the indigenous people of Sub-Saharan Africa were anything but uncultured, and in many cases managed and controlled their environment in sophisticated ways that the Europeans first ignored out of ignorance, but which they eventually either learned: 1) from the African, 2) after many failures through trial and error, or 3) through his Western “scientific approach” to study. It can be contended that if the Europeans had not tried to dominate nature and conquer the “*savage tribes*” of the subcontinent, but instead had collaborated with them, they could have avoided wasting much time and effort in learning and adopting/adapting to how Africans managed their natural resources.

European imperialism in both Sub-Saharan Africa and North America brought these continents’ evolving indigenous civilizations and the management of their natural resources to a halt and steered them into evolutionary dead ends. Cultures and in some cases entire ethnic groups were wiped out to make way for the colonial masters and their approaches to conservation.

Human populations were low relative to the resource base when the Europeans arrived. Africans traditionally practiced extensive management of their natural resources through territorial controls, taboos, totems, hunting guilds, etc. With few exceptions, wildlife was more a resource for consumption than trade, and where trade existed, relatively unsophisticated weapons combined with low human numbers limited the offtake to sustainable levels.

However, the Europeans with their capitalistic approach to wildlife and the evolution of sophisticated firearms from the musket, to the rifle, black powder and

smokeless powder, were able to impact wildlife populations in a way never before seen by Africans and American Indians in recent history.

On both continents, wildlife was first a tool of conquest played out to the end, and later a pursuit of “sporting” gentlemen. By the beginning of the 20th century, wildlife on both continents had been nearly wiped out by European settlers and measures were taken to protect it. In Sub-Saharan Africa, indigenous people were both blamed and punished for this demise; game/forest reserves and parks were created, separating people from wildlife and other key resources needed for both physical and cultural survival. Africans were separated and then excluded from these natural systems in favor of European settlers and later rich tourists, primarily from Europe and America.

In contrast, in America, orders of magnitude more of the country’s public land was placed into multiple use conservation areas (state and national forests, many state parks, Bureau of Land Management lands, wilderness areas, etc.) than into preservationist parks, though few Americans Indians remained to take advantage of this, their numbers being significantly reduced from as high as 10 million prior to the coming of the European to about 250,000 by the end of the 19th century. These public multiple use areas were available for hunting, fishing, hiking and camping, grazing livestock, timber and firewood harvesting. Over the past 50 years, monitoring programs have been established to assure that these resources are sustainably harvested.

Centralized control by the colonial powers in Sub-Saharan Africa and the state’s subsequent failure to successfully manage these resources, turned what had been “Common Property Resources” into “Open Access Resources”, of which 95% were harvested clandestinely, in other words “poached” by rural Africans for both cultural and subsistence purposes. Most pre- and post-colonial governments, with

little knowledge of intensive management other than lighting random fires in the dry season to obtain a second flush of grass, relied primarily on repression as their primary management tool, operating as paramilitary forces against communities peripheral to parks and protected areas. This approach has failed.

It can be argued, that by turning wildlife and other resources into “Open Access Resources”, Africans were forced to regard them as short-term commodities over which they had lost control and which had to be mined before the next person took them. This also favored the conversion of natural systems by rural Africans into man-made systems, “farm land”, or pasture for livestock, over which they had some control.

Just as importantly, but rarely discussed, is that Africans, through the creation of game reserves, parks and hunting blocks, and through displacement by European settlements, were compressed onto lands, whether formal or informal native reserves, that could not support their populations given the carrying capacity of the lands and their ecological limitations. The impacts of compression on farmers and pastoralists are discussed in subsequent chapters. This resulted in the loss of wildlife and its habitat (e.g., deforestation, soil degradation, over-grazing and desertification) and the general impoverishment of both people and the resource base. At worst this process of disenfranchisement in the 21st century has resulted in the continuation of eco-genocide that began under colonialism, obliterating cultures from the face of the earth that have lived in harmony with nature for hundreds if not thousands of years, sustainably managing their natural resources. This is discussed in later chapters, where it is occurring in the name of conservation and biodiversity, being fueled by money from the West funneled through over-zealous Western NGOs and African governments. These governments’ bureaucrats have largely been trained at Western universities and have adopted American and European protectionist ideologies, and/or have sold

out to the perks (e.g., vehicles, overseas trips, per diems, etc.); a form of emerging neo-colonialism.

The disruption of traditional management systems, which were replaced by failed Western systems, displacement, compression, and over-exploitation of wildlife, was compounded by the population explosion in Sub-Saharan Africa that increased about 5.5-6.5 times during the 20th century to about 622 million, the commercialization of wildlife for bushmeat to supply the demands of growing urban centers and the international ivory/horn trade. By the time independence from colonial rule came in the early 1960s, the natural resource base over most of Africa was under tremendous pressure from the growing tidal wave of human poverty. As the well-known safari operator Robin Hurt (*pers. comm.*), who was raised in Kenya explained, “When I was a boy there were ‘Islands of People’ surrounded by a sea of wildlife. Today, there are ‘Islands of Wildlife’ surrounded by a ‘Sea of People’ ”. Both he and Fred Duckworth (*pers. comm.*) estimate that wildlife in Kenya and Tanzania is 25% of what it was in their youth; a 75% reduction in numbers. These men are in their 60s. Between 1977 and 1994 alone, the overall wildlife populations in 18 rangelands districts of Kenya have decreased by 44% (Barrow, *et al.*, 2000). Due to man and the increase in his livestock, wildlife today makes up only 10% of the large herbivore biomass in Southern Africa (Cumming, 2005).

Current human populations, expected to more than double in the next 50 years, combined with failing extensive farming and pastoral systems in Sub-Saharan Africa, have placed tremendous pressure on both wildlife and its critical habitat. African governments and rural communities have a tremendous need for the introduction of intensive management systems, of which other than in a few countries (e.g., South Africa, Namibia, and in the past Zimbabwe) there is little experience, mainly in white hands. Over much of the continent, a great deal of

the traditional knowledge and controls over managing Africa's natural resources, including wildlife, have been lost or degraded in favor of failed Eurocentric approaches. Meanwhile in Southern Africa, especially South Africa, as in the USA, Western concepts of intensive wildlife and habitat management have been developed and adapted to the subcontinent over the past 200-300 years. They are applied on both game ranches and in national parks. There is a crying need to record traditional knowledge of wildlife management and to integrate it into modern Western designed and imposed management systems, taking the best of both worlds, while working in collaboration with the true stakeholders, the rural people of Africa, who will ultimately determine if wildlife on the subcontinent survives or is eliminated. These issues are discussed in detail in forthcoming chapters.

Chapter 4

4.0 IMPERIALISM, INDEPENDENCE AND FRESHWATER FISHERIES IN SUB-SAHARAN AFRICA

This is a continuum of the last chapter, but instead of wildlife, it will examine how imperialism impacted upon aquatic biodiversity, especially indigenous/endemic fish species and the socio-economic conditions of fishermen. The introduction of exotic fish species was widely practiced for many reasons, often in attempts to increase fish production, and/or to introduce “sport fish” for the colonial settlers.

4.1 INTRODUCTION

European trout have been introduced into the highlands of East and Southern Africa such as the Aberdare Mountains of Kenya, the Rwenzori “Mountains of the Moon” of Uganda/DRC, and Drakensberg Mountains of Lesotho/South Africa to recreate the “English landscape” in the underwater world, where the gentleman nimrod with fly rod and gun wandered about valleys and streams, which he mastered. In 1905/06, overly-enthusiastic “sporting” trout fishermen were responsible for the introduction of a law prohibiting the catching of any species in the Old Transvaal, South Africa between May and September, depriving rural Africans of protein (Carruthers, 1995), a law which was repealed by 1906 for certain indigenous fish species (Carruthers, 1995).

Black “largemouth” bass (*Micropterus salmoides*) was introduced to Lake Naivasha about 1929 at the instigation of Dent the Kenya Fish Warden to control the introduced tilapia (*Oreochromis leucostictus* and *Tilapia zilli*) (Parker, 2003;

Malala, Mugo1, Nyang'au, Ojuok, Mwamburi, Obade & Kundu, 2004). Black bass was introduced all over Zimbabwe's and South Africa's farm ponds and reservoirs. The red swamp crawfish (*Procambarus clarkii*) (Parker, 2003; Malala, *et al.*, 2004) was introduced in Lake Naivasha in 1972 by a local farmer, who collected them from a dam at Subukia, where they had been introduced from Kajansi in Uganda. In turn, the introduction of crawfish to Uganda was made by Israeli advisors to the Uganda Fisheries Department as food for Nile perch being reared for pond culture. The Israelis obtained them from Louisiana (Parker, 2003). There appears to be little or no understanding as to the impacts of these exotics on endemic/indigenous fish, invertebrates and plants.

De Moor and Bruton (1988) have shown that in Southern Africa, of the 58 alien and indigenous translocated aquatic animals, 37 are considered detrimental, 3 beneficial and 18 to be equivocal - that is beneficial under certain circumstances and detrimental under others. Of the 55 detrimental and equivocal species, 18 are considered to have had major detrimental impacts on indigenous species and communities. This includes the introduction of sport fish, such as the largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieu*) and brown trout (*Salmo trutta*) that have all had adverse impacts on indigenous species of fish.

In some instances the introduction of exotic species such as kapenta (*Limnothrissa miodon*) from Lake Tanganyika into the Kariba Reservoir and eventually the Cahora Bassa Reservoir, both on the Zambezi River of Southern Africa, appeared to be positive, taking up the void in a biological niche of an open lake phytoplankton feeder. This niche had not existed previously, but was artificially created by man as a result of damming this river. This has resulted in the development of major fisheries and a major protein source for the poor of Southern Africa. Was it luck, that there were no biological catastrophes

(extinctions) or was this carefully studied prior to the introduction of this species? This will be discussed more under Chapter 7 on dams (see Chapter 7, Section 7.8.5.3, Kariba Dam, Zimbabwe, Zambezi River and Section 7.8.5.4, Cahora Bassa Reservoir, Mozambique). As Graham Child (1995) explains,

“while Zimbabwean specialists continued to debate the desirability of introducing exotic fish to a man-made environment, their Zambian counterparts got on the job. An initial inoculation near Sinazongwe, midway up the Zambian shore of the lake (Kariba) in December 1966 was followed by others in 1967 and 1968 until a total of 360,000 fry had been released”.

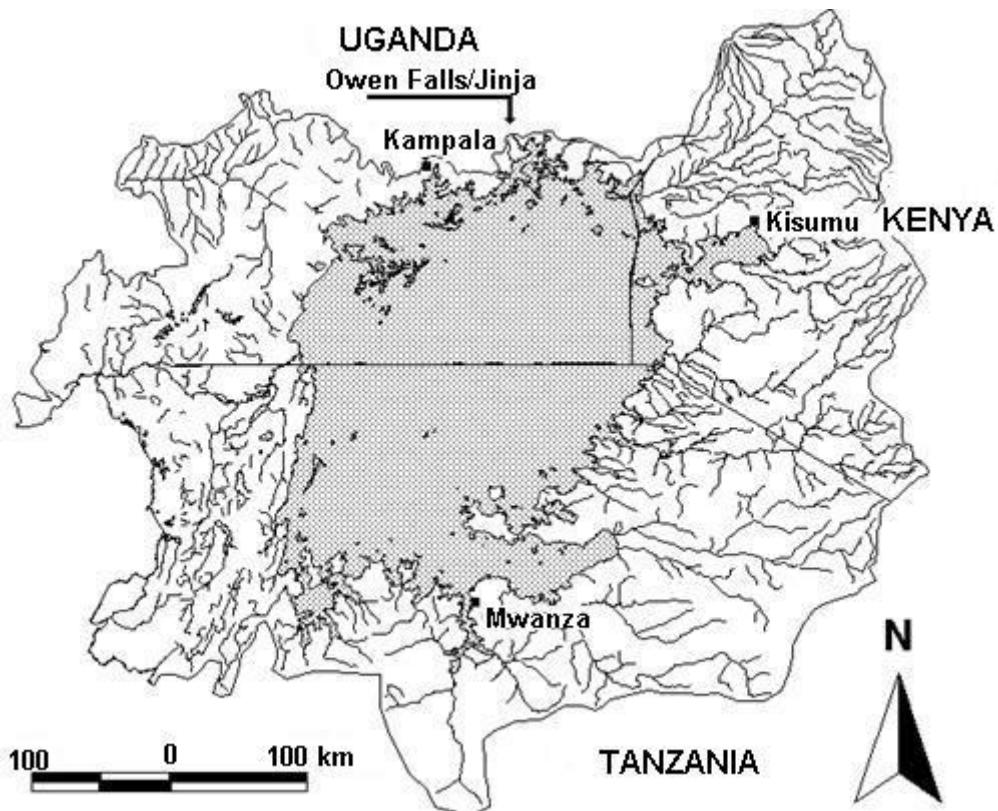

Two examples of colonial and post-colonial impacts on aquatic biodiversity and fisheries will be examined in some detail:

- **Lakes Victoria/Kyoga in the Rift Valley and**
- **Ankazomborona and Marovoay Fokotany, Mahajanga Faritany (Province), Madagascar**

The 69,000 km² Lake Victoria is the second biggest lake in the world⁴⁵, the same size as Ireland. At a human density of over 100/km², nearly 25 million people reside within the Lake Victoria Basin, one of the densest and poorest rural populations in the world. Much of the watershed has been converted to agricultural lands (Figure 4.1) (Odada, Olago, Kulindwa, Ntiba & Wandiga, 2004). However, it is relatively shallow, with a maximum depth of 84 m and a mean depth of just 40 m (Goulding, 1997), a shoreline of 3,450 km and a drainage basin covering an area of 263,000 km² (Mutunga, 2002). It is shared between three countries; Tanzania possessing 49%, Uganda 45% and Kenya 6% of the lake (Owino, 1999; Mutunga, 2002). The Lake Victoria Fisheries directly employs 100,000 people and 2 million indirectly (Mutunga, 2002).

⁴⁵ Lake Superior, North America is the largest

Approximately 90% of the fish catch from Ugandan waters in 1988 consisted of two major groups of fish; the Nile perch (*Lates niloticus*) and various species of tilapia. The dominant tilapia from Lakes Victoria and Kyoga is the Nile tilapia (*Oreochromis niloticus* or *Tilapia nilotica* or *Sarotherodon niloticus*) (DeGeorges, 1991a). This has not always been the case.

Figure 4.1: Lake Victoria and its catchment

An important freshwater fishery and wetlands are located in the *faritany* (province) of Mahajanga, approximately 560 km northwest of Madagascar's capital Antananarivo, where two fishing sites near the *fokotanys* (villages) of Ankazomborona and Marovoay were visited by the principle author as part of a joint Malagasy/U.S. Agency for International Development (USAID) team.

Additionally, the Fokotany of Ambato-Boeni in the adjoining *fivondronana* (prefecture – next level of local government) of Ambato-Beni was visited.

4.2 BACKGROUND

4.2.1 Lakes Victoria and Kyoga

The rate of speciation of cichlid fish in Lake Victoria was so rapid that the terms “evolutionary avalanche”, “explosive evolution” and “explosive speciation” have been used to describe the phenomena, resulting in the evolution of 13 families of fish in Lake Victoria divided into six cichlid and 15 non-cichlid genera, 51 non-cichlid species and over 350 cichlid species (Okeyo-Owuor, 1999).

In 1908, local fishermen first adopted factory-made nets, with the first large scale commercial fishing boom taking place from 1917-20. By 1940, there were 5 million pieces/year of the indigenous cichlid *Tilapia O. esculentus* (*ngege*) being trans-shipped by rail from Kisumu into central Kenya (Gibbon, 1997).

Prior to the introduction of the Nile perch, the haplochrome cichlids comprised at least 80% of the ichthyomass of Lake Victoria. The haplochromes were classified into 11 trophic groups dominated by detritivores and phytoplanktivores (Balirwa, 1990 In: DeGeorges, 1991a). While the bulk of the lake's biomass in the 20th century was comprised of the little-exported *Haplochromis spp.* (*furu*), and while there were commercial fisheries for *Bagrus spp.* (*hongwe*), *Labeo spp.* (*ningu*), *Clarias (Clarias) spp.* (*mumi*) and one or two other species, the main commercial fishery until the 1980s was always for *Tilapia spp.*

Ngege was never a prolific breeder and its main feeding grounds (waters at a depth of 4-20 m with a grassy floor) were easily accessible by canoe. It is

therefore not surprising that from a very early date concerns were raised about over-fishing this species.

In Kenyan waters, where nylon nets and outboard motors were introduced, inshore catches fell rapidly after 1945. An increasing movement of fisheries to camps on offshore islands was reported and in 1956 the net size regulation (mesh >5 inches) was abandoned as unenforceable (Gibbon, 1997).

4.2.2 Madagascar

Based on a 1963, study there were 165,000 ha of major lakes/impoundments in Madagascar where fishing was important and 400,000 ha of minor or secondary lakes/impoundments where there were no fishermen and/or fishing was for auto-consumption (Razafimahaleo, *pers. comm. In: DeGeorges, 1991b.*).

Marovoay was the second most important region for rice production in the country after Lac Alaotra. Many rice farmers in the area undertook fishing to supplement their income and to procure a source of protein to nourish their families. Fishing habitat included natural floodplains (temporary lakes), rice paddies and impoundments established for rice irrigation.

4.2.2.1 Floodplain fishing

Natural flooding of both irrigated fields and natural floodplains begins in November/December and continues through May of each year. The “natural floodplains” were fished from February through October. There was a direct relationship between the area flooded, duration of flooding, annual fish production, fish biomass and thus potential annual yield/catch of fish. For instance in 1991, fish yields dropped by 67% (2/3^{rds}), due to reduced flooding

(DeGeorges, 1991b). The relationship on the floodplains between dry season forage habitat for livestock and wet season fishing habitat was ecologically complementary, each contributing to the productivity of the other by recycling organic matter and nutrients. The degree of productivity of both terrestrial and aquatic floodplain systems is interdependent and symbiotic in nature (Rajonson, DeGeorges & Booth, 1991).

One advantage of the floodplain fisheries is that their rejuvenation depended on species that found refuge by returning to the major river channel and streambeds during the flood recession. The remainder of the fish became trapped in mostly temporary marshes or ponded areas, *lac tarrisables*. By the end of the dry season, most of these temporary ponds dried up and the trapped fish stocks died unless fished out completely (Rajonson, *et al.*, 1991).

4.2.2.2 Impoundment fishing

In the study area, impoundment fishing behind the dam took place during the rice culture season from May to December (DeGeorges, 1991b; Rajonson, *et al.*, 1991). There were three impoundments totaling about 3,000 hectares in surface area (Rajonson, *et al.*, 1991):

:

- Lac Amboromalandy, approximately 1,000 ha
- Lac Ambilovilo, slightly less than 1,000 ha
- Lac Morafeno, slightly less than 1,000 ha

These impoundments were created in 1950 and managed by a state run organization, FIFABE (*Fikambanana Fampanddrosoana ny Lemak'I Betsiboka*), that operated rice irrigation. Though originally intended primarily for irrigation,

as exploitable populations developed, fishing became a major, although still secondary source of income.

4.1.2.3 Rice paddy fishing

Fishing took place from January through about July in the rice fields. Flooded irrigation fields were fished first. As water receded from the fields, they were prepared for agricultural uses (Rajonson, *et al.*, 1991).

4.3 INTRODUCTION OF EXOTICS

4.3.1 Lake Victoria

The Nile perch and Nile tilapia were both introduced from the Lake Albert/Nile system. The Nile perch, also known as *capitaine*, *mputa*, *sangara*, and *mkombozi* (saviour) was introduced into Lake Kyoga in the 1950s and into Lake Victoria in the 1960s by expatriate “experts”.

Scientists opposed this, fearing that the lack of a natural predator for the Nile perch would result in the imminent destruction of the lake’s bountiful ecosystem. Despite the controversy, a colonial fisheries officer was ordered to clandestinely put the Nile perch into a portion of Lake Victoria lying within Uganda’s territory. Thereafter, it was introduced intentionally in both 1962 and 1963. By 1964, the Nile perch was recorded in Tanzania, by 1970 it was well established in Kenya, and by the early 1980s it was abundant throughout Uganda, Tanzania, and Kenya, the three countries surrounding Lake Victoria (DeGeorges, 1991a). Having no natural predators in the lake and a plethora of food, the Nile perch flourished, often reaching up to 250 kg., and eating constantly to sustain itself (TED, 2000).

The Nile tilapia was introduced in the 1950s (Reynolds & Ssali, 1990). Other tilapines introduced at about the same time as a means of increasing fishery yields include *Oreochromis leucostictus* (Ogari, 1990 In: DeGeorges, 1991a; Okeyo-Owuor, 1999), *Tilapia zilli*, *T. rendalli* (Ogari, 1990 In: DeGeorges, 1991a) and *T. melanopleura* (Okeyo-Owuor, 1999).

4.3.2 Madagascar

Exotic species were introduced largely in the 1950s in an attempt to improve the relatively poor yields from endemic fish species. These include (DeGeorges, 1991b; Rajonson, *et al.*, 1991):

- *Tilapia zilli*;
- *T. mossambica* (*Oreochromis mossambicus*);
- *T. macrochir* (*Oreochromis macrochir*);
- *T. nilotica*;
- Carp argente (Silver carp) *Cyprinus sp.* or hybrids of other carp all introduced directly or indirectly from Asia;
- *Heterotus niloticus*, like the tilapia also introduced from Africa; and
- Two species of freshwater eel, *Anguilla marmorata*, and *Anguilla mossambica* “*Dreta*”.

T. zilli was commonly found in rice paddies. *T. nilotica* and *T. macrochir* dominated the fish catches within the study area. This was compounded by the illegal introduction of a predatory aquarium fish *Fibata* (*Ophicephalus striatus*, Family Channidae, Snakehead) which escaped and which has, like the Nile perch in Lake Victoria, begun to exterminate or greatly reduce fish populations (biodiversity) in most of Madagascar's freshwater lakes (DeGeorges, 1991b).

4.4 SPECIES EXTINCTION

4.4.1 Lake Victoria, Mega-Annihilation of Species

The Nile perch, a prolific predator, is believed to have had a major negative impact on biodiversity in both Lakes Victoria and Kyoga. This was especially the case with *Haplochromis spp.*, of which there were from 150-300 species in Lake Victoria alone (Reynolds & Greboval, 1988; Orach-Meza, 1990; Okeyo-Owuor, 1999; Reynolds & Ssali, *pers. comm.*). The other Rift Valley lakes of Tanganyika and Malawi show similar species diversity. Lake Malawi is estimated to have between 500-1,000 species; many not yet described (Lewis, Reinthal & Trendall, 1986).

An extraordinary spectrum of endemic haplochrome (cichlid) fish, a result of intra-lacustrine adaptive radiation, was reduced by massive species extinctions (ca. 65%) due in part to predation by the Nile perch (Gophen, Ochumba & Kaufman, 1995). It is also believed that the introduction of the Nile tilapia (*O. niloticus*), a larger and more efficient herbivore/omnivore, could have contributed to the competitive elimination or diminution of many haplochrome species (Balirwa, 1990 *In: DeGeorges, 1991a*).

The haplochromes, while ecologically significant, were never of great importance as an economic or as a food source, being the least popular as a food source. Sun-dried, they were believed to have curative properties against measles when consumed by children (Reynolds & Greboval, 1988).

Additional species whose numbers decreased due to the voracious Nile perch in Lake Kyoga include *Protopterus sp.*, *Protopterus spp.*, *Schilbe sp.*, which became rare, and *Oreochromis esculentus (ngege)*, *O. variabilis*, and *Bagrus docmac*,

which disappeared (Reynolds & Greboval, 1988). The predatory bagrus, clarius and schilbe species may have been displaced due to intra-specific competition with the predatory Nile perch (Ogari, 1990 *In:* DeGeorges, 1991a). Over-fishing and the introduction of tilapine fish into Lake Kyoga are also believed to have contributed to the decline in endemic fish (Reynolds & Greboval, 1988). For instance, the disappearance of *O. esculentus* (*ngege*) and *O. variabilis* is believed to have taken place due to hybridization with *O. niloticus* (Ogari, 1990 *In:* DeGeorges, 1991a). Similar trends in the decline in fish species biodiversity have been seen in Lake Victoria (Ssali, *pers. comm.*).

4.4.2 Madagascar

It appears that for the most part, endemic species had been displaced or eliminated by the introduced exotics, with approximately 95-99% of the fish catches in the study area, by both numbers and biomass, being exotics. This is typical of most freshwater fish stocks throughout Madagascar (Rajonson, *et al.*, 1991). The principal endemic/indigenous species taken from the rice fields and floodplains included:

- *Arius madagascariensis*, an endemic catfish;
- *Megalops cyprinoides*, an indigenous tarpon that does not exceed 55 cm in length; and
- An endemic gobidae.

4.5 EUTROPHICATION

4.5.1 Lake Victoria

Hydrologically, Lake Victoria behaves like a closed system, taking about 73 years for a volume of water equivalent to that of the Lake, to flow out of it (Klohn & Andjelic, 2002). There are substantial increases in the chlorophyll concentration (indication of increased algal biomass) and primary productivity compared to values measured 30 years ago, with a shift in the phytoplankton community towards dominance of blue-greens and an enhancement of algal blooms. In some shallow depths of the lake, anoxic (without oxygen) waters have recently been found, suggesting significant increases of oxygen demand in the seasonally formed hypolimnion.⁴⁶ It is believed that (1) predation by the Nile perch on the native cichlid fish fauna has altered the food web and caused a trophic cascade, (2) increased nutrient inputs from the catchment or the atmosphere have resulted in the observed eutrophication, and (3) modifications in the stratification and mixing regimes of the lake brought about by climate change could be involved in the eutrophication of the lake and are not considered mutually exclusive (Okeyo-Owuor, 1999).

The decrease in the number of algae-eating fish allows the algae to grow at an alarming rate, thereby “choking” the lake. The increasing amounts of algae, in turn, increase the amount of detritus (dead plant material) that falls to the deeper portions of the lake before decomposing. As a byproduct of this decomposition, the oxygen levels in the deeper layers of water are being depleted. Without oxygen, any aerobic life (such as fish) cannot exist in the deeper portions of the

⁴⁶A rapid change in temperature with depth of 1° C or greater indicates a thermocline and the division between the upper waters of a lake (epilimnion) where circulation by wind is excellent and the hypolimnion in the lower waters of the lake where circulation is poor and often leads to anoxic conditions if there are large amounts of organic matter in the lower waters. Most tropical lakes are monomictic, turning over once a year as surface temperatures cool to hypolimnion levels.

lake, forcing all life to exist within a narrow range of depth. In this way, the Nile perch has contributed to degradation of the diverse and thriving ecosystem that was once Lake Victoria (TED, 2000).

Increased nutrient loading is also contributing to this eutrophication, even though fertilizer use is limited, from soil particles washed off the land by erosion, from burning wood-fuels, and from human and animal waste originating from both rural and urban areas draining into the lake (Klohn & Andjelic, 2002). The Lake Victoria Environment Management Program estimates 49,500 tons of nitrogen/year and 5,700 tons of phosphorous/year are loaded into the lake from non-point sources (Alweny, 2007).

4.5.2 Madagascar

With little or no baseline fishery statistical data, it was impossible to determine to what degree fish catches were changing either in yields, catches per-unit-effort or in species composition. However, a number of activities underway may have been contributing to the long-term degradation of these aquatic ecosystems, both environmentally and from the standpoint of a renewable fishery resource of important economic value.

There had been a major influx in the numbers of farmers undertaking rainfed agriculture for corn, manioc and sugarcane within the watershed of the impoundments and floodplains. Because of a scarcity of farmlands, forests of raphia palm were being cut over. This was resulting in the silting-in of impoundments and the temporary floodplain lakes, reducing their water storage capacity and their capacity as important habitat for fish production.

Because the reservoir storage capacity of the impoundments had been reduced, the increasingly rapid loss of water from the watershed during the rainy season could not be completely stored by the impoundments. As a result, this water overflowed onto the floodplains and was lost as a resource for rice irrigation.

Likewise, the loss of water retention capacity from deforestation greatly reduced critical dry season flows from the streams that fed the impoundments, resulting in insufficient water from the impoundments (e.g., Lac Amboromalandy) to meet the full water requirements for dry season irrigation. In one instance farmers had to pump water onto their fields, something they could ill afford.

Although not confirmed through interviews with local residents, fishery production within the lake was believed to be decreasing due to shrinking habitat from sedimentation and because sedimentation was probably covering over the nests of breeding tilapia, among other species. Breeding took place at the height of the rainy season and at the peak period of erosion. Secondary impacts included sedimentation beginning to fill in irrigation canals and fields. This was not unique to the case study village, but appears to be happening in the area of Ambato-Beni as the result of watershed degradation.

According to the *Eaux et Forêts* agent responsible for the Conservation and Development Project at Ankarafantsika, there was a major effort underway to keep the watershed of the all important Marovoay rice producing areas in protected forest cover. What is not known is to what degree the community was actively participating in this effort (Rajonson, *et al.*, 1991).

4.6 ADAPTATION

4.6.1 Lake Victoria

While many experts were afraid that the Nile perch would eat itself out of existence, after eating haplochromes to extinction in Lake Victoria, its diet changed to the more abundant freshwater shrimp, *Caridina sp.*, and a small pelagic zooplanktiverous cyprinid fish, (*dagaa*) *Rastrineobola argentea*, believed to be an under-exploited fishery.

The increase in biomass of *Caridina sp.* and *R. argentea* along with increased algal blooms (also potentially related to increased nutrient pollution associated with human development of the lake shore) and increased lake fly swarms were believed to be due to a reduction in haplochrome and endemic tilapine stocks that fed on these resources. Thus, ecological balance and the transfer of energy in the food chain were being redirected through these other species (Balirwa, 1990; Kudhongania, 1990 both *In: DeGeorges, 1991a*).

4.7 CHANGES IN MAKE-UP OF CATCH COMPONENT

4.7.1 Lake Victoria

From being a multi-species fishery, Lake Victoria became a “three species fishery”. Nile perch being the dominant species comprising 55% of the catch, with 33% of the catch consisting of *dagaa* (*Rastrineobola argentea*) - a small sardine like fish, - while various species of tilapia, mainly *Oreochromis niloticus* (Nile Tilapia), constituted about 10% of the catch. These three species, during the last years, have made up about 98% of the total catch in the lake. In the Kenyan part of the lake, it may be more correct to talk about a “two-species” fishery. In

1995 about 91.5% of the catch consisted of the combination of Nile perch comprising 47.2% and *dagaa* constituting 44.3% (Jansen, Abila & Owino, 1999).

4.7.2 Madagascar

See above. Since the introduction of exotics in the 1950s, exotics make up 95-99% of the fish catches by both weight and numbers (Rajonson, *et al.*, 1991)

4.8 FISH YIELDS WITH EXOTICS

4.8.1 Lakes Victoria and Kyoga

The net result of these actions has resulted in a tremendous increase in fishery yields over the last 25 years and the development of a high quality “white fish” for the export market, turning Nile perch and Nile tilapia into important sources of foreign exchange for Kenya and Uganda (DeGeorges, 1991a).

Prior to introduction of the Nile perch in Lake Kyoga, fish yields were relatively low (e.g., 4,500 metric tons in 1956). After introduction of the perch, they peaked to a high of 138,000 metric tons (MT) in 1982, but declined to 86,748 MT by 1988. This is believed to be due to over-fishing, the use of small mesh gill nets and insecurity (Orach-Meza, Coenen & Reynolds, 1989).

In the Ugandan portion of Lake Victoria the introduction of these exotics resulted in increased fish yields from 50-60,000 metric tons in the late 1970s to 107,092 tons in 1988, the Nile perch alone climbing from an annual yield/catch of less than 1,000 tons in 1981 to 92,000 tons in 1988 (Orach-Meza, *et al.*, 1989). Catch recording is difficult given the dispersed nature of the fishery and landings. Official statistics (without doubt under-recorded) from the three countries

suggested a production of around 383,000 tons of Nile perch in 1994 from Lake Victoria, with 29% landed in Kenya, 27% in Uganda and 44% in Tanzania (Goulding, 1997).

Export utilization of Nile perch catches from Lake Victoria in 1994 (quantities in metric tons) is contained in Table 4.1:

“The Nile perch trade generated an estimated US\$ 140 million/year for the three countries concerned. In the case of Uganda and Tanzania the fish provided major export earnings. The main export markets are Europe, Israel and Australia” (Goulding, 1997). By 2004, the estimated value of the Nile perch export fishery was estimated at US\$ 270 to 520 million/year (Odada, *et al.*, 2004).

Table 4.1: 1994 landings and exportation of Nile perch, Lake Victoria

	Kenya	Uganda	Tanzania	TOTAL
Landings (Metric Tons)	104,000	120,000 ¹	159,000	383,000
Exports (fillets) ² (Metric Tons)	16,493	18,000	13,500	47,993
Exports (live equivalent) (Metric Tons)	49,500	54,000	40,500	144,000
% export utilization	47	45	25	-
Export value (US\$ million)	49.0	53.5	37.9	140.4

Notes: 1) 1995 data; includes about 20,000 tones from sources other than Victoria

2) Assumed average yield is ≈33% of live weight

Source: FAO Fishery statistics in Goulding (1997) with permission, Megapesca.

4.8.2 Madagascar

The only quantitative data obtained was 1 ton/month of dried tilapia per team of 4 fishermen over a four month period caught with seines in impoundments valued at

FMG (Malagasy Franc) 1.8 million (US\$ 1,020)/four fisherman team.⁴⁷ Floodplain yields vary from year to year depending upon the area and duration of flooding (DeGeorges, 1991b).

4.9 SOCIO-ECONOMIC IMPACTS, NEW STAKEHOLDERS

4.9.1 Lake Victoria

With globalization of the fisheries, a new set of actors entered the Lake Victoria fisheries. The owners of the fish export and fishmeal factories, having no prior relationship to the traditional fishing community, are mainly Europeans, Israelis and Asians, who have completely transformed the Lake Victoria Fisheries.

4.9.1.1 Decreasing source of protein for local people

In 1996, factory purchases of fresh Nile perch accounted for probably 75% of all Nile perch caught (Gibbon, 1997). Since the artisanal fishery biomass has moved to the high priced export fishery, there has been a major decrease in less valuable species in both numbers and biomass. These small fish, once important in the diets of local people living along Lake Victoria, are no longer available as a source of protein.

Fish traditionally accounted for about 60% of the animal protein consumed by Ugandans (Ssali, 1990 *In:* DeGeorges, 1991a) and 60% of the dietary protein of lake shore communities in general (Fuggle, 2002). The average consumption of fish in Uganda was 13 kg/person/year (Orach-Meza, 1990 *In:* DeGeorges, 1991a) and was the cheapest source of protein for the average Ugandan based upon 1990 prices. Fish averaged US\$ 0.55/kg, beef averaged US\$ 1.33/kg and chicken US\$

⁴⁷ In 1991 there were FMG 1,765/\$US

2.0/kg (Ssali, 1990 *In:* DeGeorges, 1991a). The rapid globalization and development of an export market has affected the consumers, as evidenced by the present concerns about food security along the lakeshore. The price of whole fish soon was beyond the reach of the middleclass and the remains of the filleted Nile perch skeleton were considered “food for poor people” (Okeyo-Owuor, 1999).

Table fishes [tilapias, catfishes, carps, and lungfish] have declined sharply, with the most important among them, the *ngege* (*Oreochromis esculentus*), extinct but for a few scattered populations in lake basin ponds and reservoirs. Today, the composition and yields of such fish catches are virtually negligible. Extensive fish kills (e.g., from oxygen depletion), Nile perch, loss of habitat, and over-fishing have caused many fisheries to collapse and many protein sources to be unavailable at the market for local consumption (TED, 2000).

Fish that the factories are unable to collect, because of delays in arrival at camps or arrival without adequate supplies of ice, as well as fish, which the factories reject as too small or as “stale”, are processed artisanally for local sale by

“groups of four or five youths pushing *trolli* (hand-carts with axles, wheels and tires cannibalized from pick-ups). Each *trolli* was spilling over with between one and two tons of stinking fish carcasses, bought by traders (also known as *matajiri*) at the factory gates for processing...Clouds of flies swarmed round this site, which could be smelt at some distance away, and above them swarmed quantities of swallows and a variety of hunting birds” (Gibbon, 1997).

With almost all Nile perch above 1 kg going for export, what is left for the local traders and processors? It is mainly the following three types of Nile perch (Jansen, *et al.*, 1999):

- The rejected Nile perch (partly rotten or damaged fish) - according to interviews held with many factories, they reject less than 2% of the fish delivered to them;
- The fingerlings and Nile perch below 1 kg (too small for the factories), which varies between 10-35% of the total catch of Nile perch; and
- The Nile perch skeletons left after the fish has been filleted.

Meanwhile, more and more of the *dagaa* (Jansen, *et al.*, 1999; Bokea & Ikiara, 2000) along with Nile perch skeletons (Bokea & Ikiara, 2000) is going into industrial fishmeal as animal feed, denying these important remaining protein sources for human consumption.

Nutritional surveys carried out by the Kenya Medical Research Institute in some communities next to the lake clearly show that there is severe malnutrition. In the Siaya District, 30-50% of children were found to be moderately to severely malnourished, with 50-70% moderate to severely malnourished in terms of lack of zinc, iron, and vitamin A. Malnutrition-related diseases were rampant. Access to only 10 grams of dried *dagaa* would adequately address the iron, zinc and vitamin A deficiency among the children. Because of the withdrawal of so much Nile perch and *dagaa*, it is estimated that the per capita consumption of fish in Kenya between 1990 and 1996 was reduced from six to three kg/person/year (Jansen, *et al.*, 1999). Protein deficiency (kwashiorkor) is also common among children of lake communities (Bokea & Ikiara, 2000; Fuggle, 2002).

The response to this massive withdrawal of Nile perch from the local population has been that local fishermen have started to target the fingerlings of the Nile perch using non-selective mosquito nets and beach seine gear. From the point of biodiversity loss and having a sustainable production, this practice is clearly damaging. However, from the point of view of the consumers, the targeting of the

juvenile fish may to some extent have compensated for the loss of Nile perch from the local market. Although less than successful, in an attempt to rectify this problem Uganda has imposed a ban on exports of Nile perch exceeding 60,000 tons/year, reserving three quarters of all fish in Ugandan waters for local consumption. Tanzania has prohibited the export of tilapia, reserving it for local consumption (Jansen, *et al.*, 1999), as has Kenya (Josupeit, 2006).

The controversial film “Darwin’s Nightmare” by Hubert Sauper depicts the impacts of globalization on Lake Victoria’s fishery and the socio-economic consequences, Sauper declaring “ ‘I could make the same kind of movie in Sierra Leone, only the fish would be diamonds, in Honduras, bananas, and in Libya, Nigeria, or Angola, crude oil’ ” (Jacquet, 2006).

4.9.1.2 Employment

It has been estimated that during the 1980s an additional 180,000 jobs were created in the primary and secondary fields of the fisheries because of the Nile perch fishery. However, for every work place created in the modern fish export sector, it is estimated that about 6 - 8 workplaces, or potential workplaces, were lost in the traditional sector (Jansen, *et al.*, 1999). Odada, *et al.* (2004) estimate that the number of fishermen in Lake Victoria increased from about 84,000 in 1990/1991 to 122,000 in 2000. Many of these had never been fishermen, moving to cash in on this booming industry (Markussen, 2002; Odada, *et al.*, 2004). This also applies to women fishmongers, who traditionally came from the clans or sub-clans that managed fishing beaches (Markussen, 2002). In addition, “the gap between the richest and poorest fishers in some coastal areas is widening, and the gap between the benefits obtained from the fishery by vessel owners and employed fishermen is also widening” (Nyeko, 2004; Odada, *et al.*, 2004).

4.9.1.3 More wealth among fishermen

There was more wealth in the fishing community in the 1980s and 1990s than in the 1970s, as evidenced by the large number of bars, restaurants and shops, which have been established on the landing sites. The increased income has also contributed to create new employment opportunities for people who serve or sell goods to the fishermen.

Canoe ownership went from owner-operated in the 1970s to middleman-owned by wealthy outsiders looking to capitalize on the economic boom in the 1980s/90s. The fishing operations were still quite labor-intensive, using traditional sails and oars as a means of propulsion. Each boat required from two to six men for its operation. Thus for local communities, the Nile perch fishery had many positive features: Some fishermen increased their earnings manifold, while others who had been unemployed or under-employed obtained jobs as crew (Jansen, *et al.*, 1999).

4.9.1.4 Introduction of trawlers

In the 1980s as competition increased among fish processing plants, many operating at only 50% capacity, many factories acquired trawlers. Each trawler could deliver large quantities (500-1,500 kg) of fresh and undamaged fish/day at major landing points served by the insulated trucks of the factories.

For each workplace created in a trawler, seven to eight work places in the traditional harvesting sector of the fishery were destroyed. The trawlers also had adverse impacts on the ecological habitat of the lake and the destruction of local fishermen's gear. During the last few years, all the three governments of East

Africa banned trawling, though it still continues, particularly in Kenya, where 10-15 trawlers were in operation in the late 1990s (Jansen, *et al.*, 1999).

4.9.1.5 Impacts from introduction of *tembea* boat fishing

Introduced in Uganda in the mid-1990, a new technique of fishing is fast developing across Lake Victoria called *tembea* (Swahili: moving, drifting). *Tembea* fishing is done with a large *Sese* canoe, having a flat stern end to which an outboard engine is fitted. The boats operate up to 100 double gill nets with a mesh size between 15.2-22.9 cm (six to nine inches). The nets are set drifting in the evenings and hauled in the morning catching up to 1,200 kg/day. With increasing numbers of *tembea* boats, the catch has dropped significantly, but is still often five to ten times higher than the catch obtained by traditional boats (Jansen, *et al.*, 1999).

While the *tembea* boat employs on average three to five people, one more person than the traditional canoes, the catch is many times higher, resulting in displacement of labor. Many traditional fishing boats were pulled onshore or had moved to more distant and minor beaches, used only for very local subsistence fishing. Many of the people employed on traditional boats lost their jobs. Many tried, but few succeeded in obtaining employment on the *tembea* boats (Jansen, *et al.*, 1999).

The ownership structure of the fleet was radically shifted to rich people, investing up to US\$ 8,403 (Kshs 600,000) in each fishing unit, coming from other businesses such as transport and hotels (Jansen, *et al.*, 1999).

Like the trawlers, *tembea* boats are, in contrast to the traditional boats, able to supply large amounts of fresh fish to the factories, offering a higher quality than

the fish landed by the slow moving sailing boats. The *tembea* boats fish as a fleet and when the catch goes down in one area, the fleet moves to another beach, completely undermining the operations of locally based traditional boats by over-fishing their grounds and destroying their gear. The *tembea* boats sell through the local fishing cooperatives, pay a 10% commission to the coop on the price they receive, hire the relatives of important people, and take care of the chiefs and government fish scouts, thus aligning themselves with the local elites and the government representatives by buying themselves “protection”. Crime and piracy of gear and motors of *tembea* fishing boats are on the rise, many of the “pirates” said to be traditional fishermen put out of business (Jansen, *et al.*, 1999).

4.9.1.6.1 Impacts on women from globalization of the fishery

The traditional fishmongers, the majority of whom are women, and their close relations with fishermen are now being severed, as the fishermen contract to deliver to the processing agents with better prices (Okeyo-Owuor, 1999). Lately many women, having accumulated capital from work in the processing and trading sector, have decided to invest in boats and gear. Some women own and manage the fishing operations of small canoe fleets (Jansen, *et al.*, 1999).

4.9.2 Madagascar

The majority of fishermen appeared to consist of professional migrants with local part-time fishermen working under them as field hands. There were about 200 fishermen including locals and immigrants. They rented *pirogues* from farmers at US\$ 167-222 (30-40,000 FMG)/month/metal boat and US\$ 84 (15,000 FMG)/month/wooden boat.

Not having access to credit, the average local fisherman could not afford to lay out the one time cash payment for a net (e.g., a 10 meter seine, 2.5 meters deep, with 2.5 cm mesh made from #6 line costs US\$ 833/150,000 FMG) and thus became a field hand for the professional migrants (Rajonson, *et al.*, 1991).

4.9.2.1 Splitting the profits

As field laborers for the professional fishing owners of the nets, the local fishermen only gained a very small percentage of the real value of the fish catch. Traditionally, 50% (1/2) of the catch went to the owner of the net. The other half (50%) of the catch was split up by the fishermen, in many cases the owner being one of the three to four fishermen. It was estimated that the owner of the net could pay off a net in 15-20 days of fishing. Thus, his inability to access credit keeps the local part-time fishermen from attaining economic independence and from realizing the real value of the resource. This problem was identified as a major issue in the three villages of the study area (Rajonson, *et al.*, 1991).

4.9.2.2 Sex and age stratification

Seines with 2.5 cm mesh were the principal fishing gear used in the freshwater areas described during this case study. Cast nets (*epervier*) were of secondary importance. Fish traps were placed in irrigation canals and likely small narrow streams. While commercial artisanal fishing was a man's activity, hook and line on raphia palm cane poles was used by women and children to catch fish for personal consumption (Rajonson, *et al.*, 1991).

4.9.2.3 Conflicts

There were major conflicts between using the freshwater impoundments for the irrigation of rice and as a fishery resource. The installation of temporary fishing homes around the impoundments and rice paddies by migratory fishermen resulted in the following conflicts with rice farmers:

- The impoundment water was being polluted as a potable water source for downstream farmers working in the rice paddies;
- The fishermen were decreasing water available for rice irrigation by opening sluice gates in impoundments to decrease water volume and increase fish concentrations, thus increasing catchability; and
- Temporary houses placed by fishermen on dikes, and fish traps placed in canals and not removed at the end of the fishing season eventually blocked outflows from dam to irrigation canals leading to rice paddies.

In order to resolve this conflict, a meeting took place in 1990 with the fishermen (both migrants and fishermen/farmers), the *fokotany*, *Eaux et Forets* and FIFABE. It was recommended that fishing in impoundments be put off until October, after the rice harvest. While this was agreed to, some fishermen, without permission, had begun fishing in the impoundments (Rajonson, *et al.*, 1991).

4.10 FISHERY MANAGEMENT

4.10.1 Lake Victoria

The presence of a centralized management system dates back to the colonial period when the first institutions were set up to manage the fisheries and the first formal fisheries regulations were adopted. An important institution was The Lake

Victoria Fisheries Service, which was established in 1947. Although government institutions had been established to manage the fisheries and assist the fishermen, these institutions played a rather insignificant role up to the early 1970s. In the 1960s and 1970s, the government-employed “fish scouts” played a positive role in the management of the fisheries alongside and in cooperation with the traditional clan elders. A rather detailed description of traditional fishery management on Lake Victoria is contained in Chapter 2 of this book (Section 2.2, TRADITIONAL FISHERIES MANAGEMENT) (Owino, 1999).

To cope with the dramatic changes, which occurred in the Lake Victoria fisheries as described above, the Government of Kenya adopted a new Fisheries Act in 1989, which was revised in 1991. The Act has greatly affected local community participation in the management of the fisheries. At the local level, in the fishing villages (beaches), the government fish scout implements rules and regulations of the Fisheries Act. Fishermen caught using illegal nets have been threatened and intimidated by fish scouts demanding bribes from the fishermen in exchange for their confiscated nets. About 20-30 years ago, the real wage of the fish scouts was much higher than today and with a richer fishery than in the 1970s, the temptation to augment one’s salary by questionable methods has increased (Owino, 1999).

Today, many fishermen interviewed felt that the responsibility of managing the fisheries has been taken away from them (Owino, 1999; Mutunga, 2002). “We no longer own the lake. We are only expected to fish and go away since it is the role of the Government to manage the lake” (Owino, 1999)

What was a “Common Property Resource” has now become an “Open Access Resource” with illegal mesh sizes catching under-sized fish, fishing in spawning and nursery grounds, trawlers are fishing inshore closer than the five nautical mile

limit, there no longer being limits on licenses for fishing canoes as a way of controlling fishing effort, and the role of the beach committee, previously made up of elders in regulating the fisheries in a co-management effort with government, having been eroded (Owino, 1999).

“Ultimately, the unrestricted access status of the lake and lack of enforcement of existing legislation are linked to increasing and crippling fishing effort...Overfishing and the use of damaging or illegal fishing gear is only in part a reflection of the failure of centralized management strategies on the lake, and are symptomatic of broader social, economic, and developmental dislocations such as poverty, lack of employment, etc. Theft (of fishing gears, vessels, etc.) and piracy are rampant on the lake, and may become worse as the disparity in distribution of benefits from the fishery becomes more polarized” (Odada, *et al.*, 2004).

In trying to get back control over their fishery, an elder head of the beach committee of Tako Bay organized a vigilante group to patrol the waters and protect the area from illegal fishing between 1984 and 1993 (Owino, 1999).

The fishery scouts did not like this, as it prevented them from taking bribes from illegal fishermen, ordering the withdrawal of the vigilante group (Owino, 1999). Local fishermen no longer feel responsible towards the lake, having been undermined by corrupt government fisheries officials colluding with unscrupulous fishermen to plunder the fisheries’ resources (Mutunga, 2002). The government officials argued that according to the Fisheries Act, it is the government’s responsibility to protect fish spawning and breeding grounds and that the beach leader and his vigilante had no *locus standi* i.e. the rights recognized in law (Fisheries Act) to protect the fisheries (Owino, 1999).

4.10.2 Madagascar

Traditional community controls over fishery and other wetland resources existed but were lost during colonialization and the extension of colonial laws during post-independence until today. The major organization in the study area was the state owned FIFABE, which was established in 1953 to operate the three freshwater impoundments and expand paddy rice. It had become a major mediator in resolving conflicts between using the impoundments for both fishing and irrigation water storage. In the area of the case study, the fishery resources appeared to be a Common Pool Resource available to anyone in the community who wished access. It fell somewhere between an unmanaged "Open Access Resource" and a community managed "Common Property Resource".

While jointly, the local government at the level of *fokotany* (Village) and *Eaux et Forêts* controlled access to area fisheries, little or no control existed over-fishing effort or gear, both of which can have a major impact on the sustainability of fishery stocks, especially in the impoundments. The mesh size limitation for all fishing gear used in permanent water bodies, including the three impoundments in this case study, were not to be inferior to 4 cm (stretched) for seines and 3 cm (stretched) for cast nets. While legal for floodplain exploitation, where ponds needed to be fished out before they dried up, illegal seines of 2.5 cm mesh (stretched) were commonly used by everyone in the region, even on permanent lakes, with the risk of fishing out the impoundments of viable exploitable stocks. Since the number of nets and the number of fishermen were also not regulated, there was no control over-fishing pressure and the sustainability of the fishery (Rajonson, *et al.*, 1991).

There was no national law governing the opening and closing of the fishing seasons. Each local government determined when to open and to close fishing seasons

according to their own criteria such as water level and reproductive season of local fish species. In the Faritany of Mahajanga, the official season for inland fisheries was from July through October. There was also a closed fishing season corresponding to the major period of reproduction and growth, and floodplain inundation from December through March of each year. However, fishing throughout the region began as early as January during the reproductive period or before many fish (especially tilapia) had a chance to grow more than a few inches diminishing the potential economic value of this resource. Fishing during the locally closed reproductive season (December-March), risked fishing out the reproductive stocks before they had a chance to produce a new recruitment of juveniles. This was especially critical in the impoundments (Rajonson, *et al.*, 1991).

4.11 THE FUTURE

4.11.1 Lake Victoria

There is strong evidence that the Nile perch is being over-fished. First reports of declining unit catches in the Tanzanian section of the lake date exist from 1994 (Gibbon, 1997). The average size of landed fish has declined from over 50 kg in 1980 to less than 10 kg in 1996. Catch rates are also reported to be in decline (Goulding, 1997). “By 1998, total Nile perch catches were half those at the beginning of the decade despite increased effort, and catches of *dagaa* (*Rastrineobola argentea*) have also leveled off despite increased effort” (Odada *et al.*, 2004). The population of Nile perch in the total biomass of the lake is down from 90% in 1980 to less than 50% in 2005 (Josupeit, 2006). Odada, *et al.* (2004) place the cause of declining yields to a variety of factors from watershed degradation, pollution, improved technologies (20-30% contribution), and increased fishing effort encouraged from competition by the large number of under-supplied fish factories in an era of declining fish catches and fish stocks. There are 11 fish

factories in Uganda, 12 in Kenya and 12 in Tanzania. To this, one must add the modified lake trophic status from introduction of the Nile perch and Nile tilapia, and in recent times the record low lake levels (Josupeit, 2006) due to decreased rainfall and over-release of water for hydropower (see Chapter 13, Section 13.11.1.3, Nile Basin Initiative [NBI]). Fisheries scientists believe that the Nile perch fishery is being sustained only by cannibalism of the young fish. The future sustainability of the fishery will depend on a reduced volume of catch, with better economic utilization through the sale of higher value export products to niche markets combined with improved environmental management to ensure that the lake ecosystem achieves stability (Goulding, 1997). On the positive side, with the drastic decline in the Nile perch stock, there has been a “re-emergence of indigenous fish varieties such as catfish, mudfish and lungfish”, and some *Haplochromis* species thought to be extinct have reappeared. Already a number of fish factories along the lake have closed down (Josupeit, 2006).

4.11.2 Madagascar

Fishermen and *fokotany* executive members felt that if given an opportunity to control effort, the local fishermen could advise local decision makers and *Eaux et Forêts* or fishery agents on such fishery management issues in order to sustainably manage this resource. This was believed to be a critical step in managing impoundment and permanent lake fisheries (Rajonson, *et al.*, 1991).

4.12 CONCLUSION

As has been the case all over the world, the introduction of exotic species has resulted in major extinctions and/or reduction of indigenous/endemic species in Sub-Saharan Africa. In the case of fish, this was undertaken to increase production and/or to recreate the European landscape (e.g., trout) in Africa where the English nimrod with

fly rod and gun could traipse through Africa's "hill and dale", only instead of kicking up a stag in the Abadares of Kenya, it might have been a reedbuck or lion. In many cases, the commercialization of fish brought in outsiders who displaced artisanal fishermen, forcing them to work as hired hands, to move into another vocation and sometimes into conflict. In some cases, the extinction of traditional species used for food, because of the introduction of exotic species and/or because of its commercial export, has resulted in people being worse off nutritionally. Loss of traditional management controls through centralization in the hands of government has, as with wildlife and forests, created "Open Access Resources", often being mined through mismanagement by corrupt government officials and outsiders, risking to cause a collapse in these fisheries. As with terrestrial resources, a major step forward must be to re-empower fisher communities to manage their fisheries and wetlands, by dividing lake/reservoir shores into community controlled management units with geographically defined boundaries. Within these areas, communities can control fishing effort (e.g. number of canoes/nets), mesh size, establish nursery areas and control access by outsiders. According to Bokea and Ikiara (2000), Nyeko (2004) and Ong'ang'a (2006) a proposed beach co-management system between government and fishing communities is being considered for Lake Victoria.

Chapter 5

5.0 AGRICULTURE IN SUB-SAHARAN AFRICA (SSA) SINCE COLONIALIZATION

“Africa could grow enough food for two or three times its population. It could have more wild protein, fish and livestock than it can eat or sell. And its people could be flourishing. Africa was most likely Eden, where man began. It was never a lush garden of food for the taking. Soils were mostly poor, and life was fraught with disease and danger. But there was a great wealth and potential. In less than a century, at a steadily increasing pace, Eden has been squandered recklessly. Today, much of it teeters at the edge” (Rosenblum & Williamson, 1990).

“The only answer to food security is to concentrate on the dozen or so countries (in Africa) that can produce food (commercially) and then find a way to distribute it within Africa. But if I said that in public, American farmers will kill me”, (USAID official *In*: Rosenblum & Williamson, 1990).

“Agricultural-led development is fundamental to cutting hunger, reducing poverty (70% of which is in rural areas), generating economic growth, reducing the burden of food imports and opening the way to an expansion of exports” (NEPAD, 2002).

“Africa faces two major challenges. The first is to ensure that its natural resources serve as the basis for economic growth that will result in more active and sustainable participation in the global economy. The second is to ameliorate the degradation of the natural resources and erosion of biodiversity in order to improve systems' resilience. These challenges are made all the more daunting by the fact that it is not sufficient to simply stop the degradation. Consistent efforts must be made in the short- to medium-term to build up the resources to levels never before attained in order to meet the demands of a population growing at more than 3% a year” (NEPAD, 2002).

5.1 INTRODUCTION

Often thought of as tropical, approximately 70-75% of the Sub-Saharan African continent lies within the savanna biome (Figure 5.1) (see Section 5.9.4.7, Deforestation in savanna environments). “Tropical Africa”, that is Africa South of the Sahara, is 33% savanna and 40% desert or steppe (Martin & O’Meara, 1995), leaving about 27% as forest/other vegetation (Martin & O’Meara, 1995; FAO, 2000a). Savannas are one of the world’s major biomes and in Africa contain the majority of the mega-fauna. Savanna is a tropical vegetation type co-dominated by woody plants and grasses and includes arid shrub lands, lightly wooded grasslands, deciduous woodlands and dry forests; tree canopy varying from 5-90% (Scholes, 1997 *In:* Cowling, Richardson & Pierce, 1997). If the transition ecotomes between are included, then savannas can be defined as constituting up to 70-75% of the habitat south of the Sahara (Sub-Saharan Africa), the figure (75%) used by Child (1995; 2004b both *In:* Child, 2004a):

- 1) Between savannas and forests, and between savannas and grasslands/arid shrub lands [e.g., Sahel, Northeast Arid Region (Somalia and parts of Ethiopia) and the Southwest Arid Region (Nama-Karoo and Succulent Karoo of Northern Cape and the Kalahari of Namibia and Botswana)], and
- 2) Miombo (*Brachystegia* spp.) and mopane (*Colophospermum mopane*) woodlands (Tropical deciduous scrub), which some might classify as forests but which are really savannas.

Child (2004b *In:* Child, 2004a) states:

“these savannas...where crop and livestock production, on a broad scale without irrigation are economically hazardous and faltering. Put bluntly, conventional agriculture is not sustainable in vast areas of these savannas under present or foreseeable international

production and marketing conditions...compounded by deteriorating terms of trade for ubiquitous agricultural commodities like red meat or cereals...By contrast, the value of the spectacular African macrofauna...is increasing as demand for wildlife-based activities escalates".

Many people talk of desertification and climate change causing the Sahara to move southward. As is discussed below and in the next chapter, in the mid-19th and 20th centuries, ill-advised agricultural policies, the introduction of inappropriate farming and animal husbandry practices, boreholes, over-grazing and the destruction of indigenous agricultural systems that had achieved a delicate ecological balance through generations all resulted in increased soil erosion and climate change. The net result was creation of what many believe to be man-made desertification. The development policies of governments, often designed, funded and staffed by international donor agencies, all too frequently have exacerbated the problem through ill-advised actions (Martin & O'Meara, 1995) and policies. This linked to a human and livestock population explosion in the 20th century that can be tied to colonialism, has spelt catastrophe for agriculture, the people and the environment across the subcontinent.

5.2 ECONOMICS OF AGRICULTURE IN AFRICA

The majority of poor in Africa are smallholders. Over 96% of farmers operate on a small-scale, farming less than five ha (Roman, 2003). The sector, however, is characterized by weak linkages to markets and little or no access to external inputs. Many small-scale farmers farm already degraded land (and/or marginal land that will soon be degraded), and most are far from services and roads and consequently from extension programs. In Sub-Saharan Africa (SSA) agriculture accounts for 20% of the Gross Domestic Product (GDP)⁴⁸ and employs 67% (60-

⁴⁸ Gross Domestic Product (GDP) is the market value of new goods and services produced by the input factors (capital and labor) located within the geographic boundaries of an economy. Gross

70%) of the labor force (Maxwell, 2001 *In:* Devereux & Maxwell, 2001a; Roman, 2003). Alemayehu (2000) estimates the figure to be 30% of the GDP. The Commission for Africa (2005) estimates that agriculture accounts for 30% of Africa's GDP while in developed countries agriculture accounts for a few percent of GDP or less with only around 5% of the population depend on farming. As the African continent urbanizes fewer people are employed in agriculture and agriculture is less important to the continent's economy. Currently, 30% of Sub-Saharan Africa's labor force is in industry and services, which contributes about 90% to the GDP (Roman, 2003). Sub-Saharan Africa is the only region where the annual growth of per capita GDP has been negative, at -1.0%/year between 1975 – 1999, compared with 6.0%/year for East Asia and the Pacific and 2.3%/year for South Asia (Roman, 2003). Africa's per capita GDP fell from US\$ 671 in 1975 to US\$ 245 by 1997, most Africans being worse off than 25 years earlier (Zack-Williams, 2002 *In:* Zack-Williams, *et al.*, 2002). Africa's exports account for only 1.6% of global trade despite Africa having 13% of the world's population. In agriculture, the share of Africa in world exports has dropped steadily, from 8% in 1971-1980 to some 3.4% in 1991-2000 (NEPAD, 2002). Kousari (2004) estimates that "Africa's share in world exports fell from about 6% in 1980 to 2.0% in 2002, and its share of world imports from about 4.6% in 1980 to 2.1% in 2002".

Timmer (1990 *In:* Eicher & Staatz, 1990), depicts the evolution of agriculture through four phases starting with a situation in which the majority of the people

Domestic Product (GDP) allocates product according to the *location* of the owners of the factors. GDP = Output produced within a country's boundaries = GNP - Net Factor Payments (NFP). NFP are payments to domestic factors located abroad minus payments to foreign factors located in the domestic country. Gross National Product (GNP) allocates product according to the *nationality* of the owners of the factors. Gross Domestic Product (GDP) = output produced by domestically owned factors of production anywhere in the world, GNP = GDP + NFP (Mohammadi, 2004) = Gross National Income (GNI) with the following added - also includes a terms of trade adjustment and gross capital formation, which now includes a third category of capital formation: net acquisition of valuables. Included in gross capital formation under the 1993 System of National Accounts (SNA) are capital outlays on defense establishments that may be used by the public, such as schools, airfields, and hospitals (World Bank, 2004).

work in agriculture, while slowly evolving and integrating into a broader economy, to a point where the labor force in farming falls below 20%. Africa appears to be stuck in phase 1 (Eicher, 1990 *In: Eicher & Staatz, 1990*), and the question is how to move beyond this stage, especially as human population pressures combined with traditional farming practices are making it more and more difficult for the rural labor force to maintain a decent quality of life. Eicher (1990 *In: Eicher & Staatz, 1990*) believes that getting agriculture moving will require long-term investments in human capital, rural infrastructure and agricultural research, the “prime movers of agricultural development”.

As early as the 1960s, French agronomist, René Dumont (1966) believed that agricultural revolutions in England and America facilitated the Industrial Revolution. He believed that progress in agriculture should not be considered as preliminary to industrialization, but as an indispensable corollary, in many cases the raw products from agriculture feeding agro-industries. Without industry, without resources of energy except manpower, without modern methods of high yield agriculture and thus without buying power, a vicious cycle is established resulting in resource degradation and increasing poverty. Alemayehu (2000) supports René Dumont’s conclusions adding that in most African countries, the food industry is the lead industry (e.g., in 1985, contributing to 62% of manufacturing in Burkina Faso and 77% in Rwanda).

5.3 FOOD PRODUCTION

5.3.1 Global Food Production

5.3.1.1 Worldwide over-production of food, a big question in the 21st century

Food security implies the ability to acquire enough food to satisfy adequate nutritional requirements at both national and household levels (UNECA, 2003). More than 70 million people died in famines worldwide during the 20th century. However, the link between crop failure and famine was broken in the late 20th century, due to the development of effective humanitarian responses by the global community. Likewise, outside of Africa famine mortality has been virtually eliminated due to effective food aid responses from the global society (Devereux, 2000). Thus, famine is not just about crop failure but represents a complex biological, technical, social and political problem existing since biblical times (Eicher, 1990 *In:* Eicher & Staatz, 1990) (Table 5.1).

Table 5.1: The number of people dieing from famine by region of the world and by decade

Decade	East Asia	Europe	SE Asia	South Asia	Africa	Total
1900s	-	-	-	-	42,500	42,500
1910s	-	-	-	-	155,000	155,000
1920s	7,000,000	9,000,000	-	-	-	16,000,000
1930s	-	7,500,000	-	-	-	7,500,000
1940s	5,000,000	2,010,000	-	2,550,000	300,000	9,860,000
1950s	15,750,000	-	-	-	248,500	15,998,500
1960s	15,750,000	-	-	-	1,052,500	16,802,500
1970s	-	-	1,750,000	1,630,000	471,000	3,851,000
1980s	-	-	-	-	1,425,000	1,425,000
1990s	-	-	3,150,000	-	470,000	2,470,000
Total	43,500,000	18,510,000	4,900,000	4,180,000	4,164,500	75,254,500

Source: Devereux (2000) with permission, ITDG Publishing/University of Natal Press. East Asia = China, Taiwan, Japan, North/South Korea. Southeast Asia = 11 countries south of China. South Asia = Bangladesh, British Indian Ocean Territory, Bhutan, India, Maldives, Nepal, Pakistan & Sri Lanka

Over the last 35 years, global per capita food production outstripped population growth by 16%. The world had more food available per person than ever before in human history. One of the greatest problems faced by the world's farmers was over-production resulting in low farm prices. Food insecurity did not result from an absolute shortage of food, but had economic roots (e.g., poverty). The problem was that food was unevenly distributed (Copeland, 2000).

Globally, even after the doubling of world grain supplies, the share of trade in total grain consumption has remained stable at about 10%. Thus, by and large, most of the world's food consumption takes place in the countries in which it is produced (NEPAD, 2002), which is that much more of a reason for Africa to look towards increasing grain production on the continent.

The 1996 World Food Summit (WFS) set a global target of a reduction in the number of hungry people by at least 20 million/year between 2000 and 2015 (see Chapter 13, Section 13.12.3, Role of Private Sector Versus Foreign Aid in Economic Development). The latest figures demonstrate that the average annual decrease in undernourished people since 1996 is 2.5 million/year, well below the goal of halving undernourishment⁴⁹ by 2015. For this to happen now would mean a decrease in undernourishment by 24 million people/year, almost 10 times the current pace, in order to reach that goal (Roman, 2003).

"It is estimated that if the self-sufficiency ratio in Sub-Saharan Africa is to stay the same in 2015 as in 1995-97 (about 85%), the subcontinent will have to meet 118 million tons of its projected needs of 139 million tons of cereals through increased production

⁴⁹ **Undernourishment** is defined as getting under a certain minimal caloric intake/day, generally 1,720-2,300 calories/day for an adult depending upon the reference (see Section 5.4, HUNGER LINKED TO POVERTY). **Malnourishment** is not getting sufficient dietary nutrients such as amino acids/protein (e.g., kwashiorkor), vitamins (e.g., vitamin A deficiency impairing the immune system) or minerals (e.g., salt/ iodine, iron-deficiency anemia).

in the region itself, requiring a substantial increase of output. These stark realities highlight the huge scale of the problem” (NEPAD, 2002).

If current figures provided by Brown (2003a; 2003b) on global grain deficits are accurate (see below), a significant reduction in Africa’s undernourishment may be an unachievable goal, especially if it relies on foreign food aid. South Africa is the only country in Sub-Saharan Africa that is relatively food self-sufficient.

5.3.1.2 Keeping up with future demand – global deficits of the 21st century

However, can agriculture provide for the food needs of a world population projected to exceed 7.5 billion by the year 2020? Concern is growing that it may not be able to.

According to Lester Brown and analysts at the environmental think-tank, the Earth Policy Institute, the idea of a global grain surplus began changing around the year 2000 when the first global grain deficits were observed. By 2003, this amounted to a global shortfall of rice, wheat and corn of 96 million tons. In 2004, 100 million additional tons of grain were needed just to break even with the 2003 deficit. Henri Josserand, Chief of FAO’s Global Information and Early Warning System, expected cereal production to be close to total levels of utilization in 2004/2005. A cereal output forecast an increase in cereal production, by 29 million tons to 1,985 million tons. If so, the need for another major drawdown in global cereal stocks would be averted. Josserand agreed that in the previous four years, cereal stocks had been declining sharply (FAO, 2004). How long can global cereal production keep up with demand?

There are indications that the highly productive fertilizer and seed technologies introduced over the past three decades may be reaching a point of diminishing

returns (Bouis, 1993; Cassman, DeDatta, Olk, Alcantara, Samson, Descalsota & Dizon, 1995; Flinn & DeDatta, 1984 all *In: Gruhn, Goletti & Yudelman, 2000*) (see Section 5.12.1.2, Green Revolution technologies). Prospects for expanding low-cost irrigation, one of the driving forces behind yield increases, are also becoming more limited (Rosegrant & Svendsen, 1993; Rosegrant, 1997; Carruthers, Rosegrant, & Seckler, 1997 all *In: Gruhn, et al., 2000*) (see Section 5.12.1.3, Irrigation potential), as are the prospects for converting marginal lands into productive arable land (Bockman, Kaarstad, Lie & Richards, 1990; Crosson & Anderson, 1992 both *In: Gruhn, et al., 2000*). Furthermore, new technologies such as genetically engineered, yield-increasing plants are not expected to be major factors in food production increases in developing countries during the next two decades (Hazell, 1995; Peng, Khush, & Cassman, 1994 both *In: Gruhn, et al., 2000*). Genetically modified (GM) high yielding crops and irrigation were the basis of Nobel Prize winning Norman Borlaug's 1960s "Green Revolution". Consequently, keeping pace with population growth and increasing land scarcity will pose major challenges compared to the recent past (Gruhn, *et al.*, 2000). FAO (2002a) identifies the shortcomings of the Green Revolution as:

- "It was heavily geared to the world's three leading cereal crops (wheat, maize/corn and rice), which were suited to its emphasis on maximizing yields. Other crops, including many that are important in Sub-Saharan African, such as cassava, millet, sorghum, banana, groundnut and sweet potato, needed a different approach.
- It was suited only to areas with good soils and water supplies, and largely neglected the more marginal rainfed areas with problem soils and uncertain rainfall.
- It relied on farmers being able to afford inputs, and did little for poor smallholders with insufficient funds or access to credit.
- Finally, it largely ignored the possible environmental consequences of high input use, such as the pollution of water and soils with nitrates and pesticides".

For instance, after the 1973-74 Sahelian famine, of the US\$ 11 billion spent in the Sahel until the next major drought a decade later, only 1.4% was spent on soil and

water conservation and 4% on rainfed crops (Rosenblum & Williamson, 1987) (see Section 5.6.3.2, Foreign assistance in Sahel goes for large scale as opposed to improving traditional agriculture).

Brown and his staff have come to similar conclusions, believing that the failure to develop still higher yielding grains, falling water tables (e.g., from irrigation, human and industrial consumption) and increasing temperatures (e.g., global warming) are the main reasons that crop production is not increasing, while human populations continue to climb. Brown is concerned that growing global deficits will result in rising food prices, and that there will not be enough grain to go around for the 100+ countries that import grain. This could result in political destabilization, as has been seen in a number of African countries when the price of flour and thus bread was increased (Brown, 2003a; 2003b). Thus achieving food security through redistribution of grains to the poor across international boundaries (Mellor, 1990b *In:* Eicher & Staatz, 1990) as is being practiced through globally subsidized humanitarian assistance may not be sustainable in the long-term if trends continue.

To counter this, FAO predicts that world agricultural output will pick up and grow 1.6%/year to 2015, outstripping the global population growth of 1.1%/year. Maxwell (2001 *In:* Devereux & Maxwell, 2001a) raises the problem of the global population increasing by 90 million people/year, requiring an extra 30-40 million tons of grain/year to feed them. World grain production peaked at 380 kg/head/year in 1985, dropping to 350 kg/head by 1993. However, it is predicted that developing countries will become increasingly dependent on imported cereals (Madeley, 2002). The question that must ultimately be asked is whether Sub-Saharan Africa can afford to sit back and assume that it will be fed by the rest of the world, given the apparent grain shortages over the last four years and a population that will more than double in 50 years to about 1.8 billion people?

Global warming raises increasing concern over food production in Africa. Madeley (2002) cites an FAO study that climate change could cause severe drought in parts of Africa by 2050, placing an additional 30 million Africans in danger of famine. At the turn of the century, the World Bank (2000) estimates that 60% of Sub-Saharan Africa is vulnerable to drought and 30% extremely vulnerable.

There is also growing concern that with increasing fuel prices, instability in the Middle East and projected 40-70 years of cost-effective fossil supplies, alternative fuel technologies will be increasingly necessary (see Chapter 13, Section 13.7.2, Western Foreign Policy and Multi-Nationals Exploiting Africa). Maize and soy bean production that used to feed people directly and/or indirectly through use as livestock fodder, may be increasingly converted to biofuels, ethanol and bio-diesel respectively. The U.S. Department of Agriculture (USDA) estimates that 11% or 2.54 million tons of America's 2005 maize crop was used to create ethanol. U.S. production of ethanol and bio-diesel is projected at 28.4 billion liters (7.5 billion gallons) by 2012, or 5-7% of total petrol consumption (Stebbins, 2005). The U.S. production goal is 133 billion liters (35 billion gallons) of renewable fuel a year by 2017 (Runge & Senauer, 2007). U.S. ethanol production, primarily from corn, totaled 10.64 billion liters [(2.81 billion gallons) in 2003 (up from 8.10 billion liters (2.14 billion gallons) in 2002] with production projected to increase to 12.11 billion liters (3.2 billion gallons) by 2025 (U.S. Dept. of Energy, 2005). It takes 2.69 kg of corn grain to make a liter of ethanol (Ferguson, 2004). Of a projected global maize production of 666 million tons, 36.5 million tons, or 5.5% of total global production, will be used to produce ethanol in 2005 (IGR, 2005). This is also resulting in increased rice and wheat prices as farmers replace their fields with corn as corn prices increased to over US\$ 4.38/bushel (dry measure equivalent to 35.24 liters) in March 2007 and could climb as high as US\$

5/bushel if oil increases to US\$ 80/barrel. It is projected that given continued high oil prices, the rapid increase in global biofuel production will push global corn prices up by 20 percent by 2010 and 41 percent by 2020 (Runge & Senauer, 2007). This implies that sooner than later, there may be less and more costly grain to feed the people of the Developing World who have grown accustomed to living on food produced from the First World. Regardless of the cost of transportation, or global warming, the food may just not be there, as it will be converted to an alternative energy source.

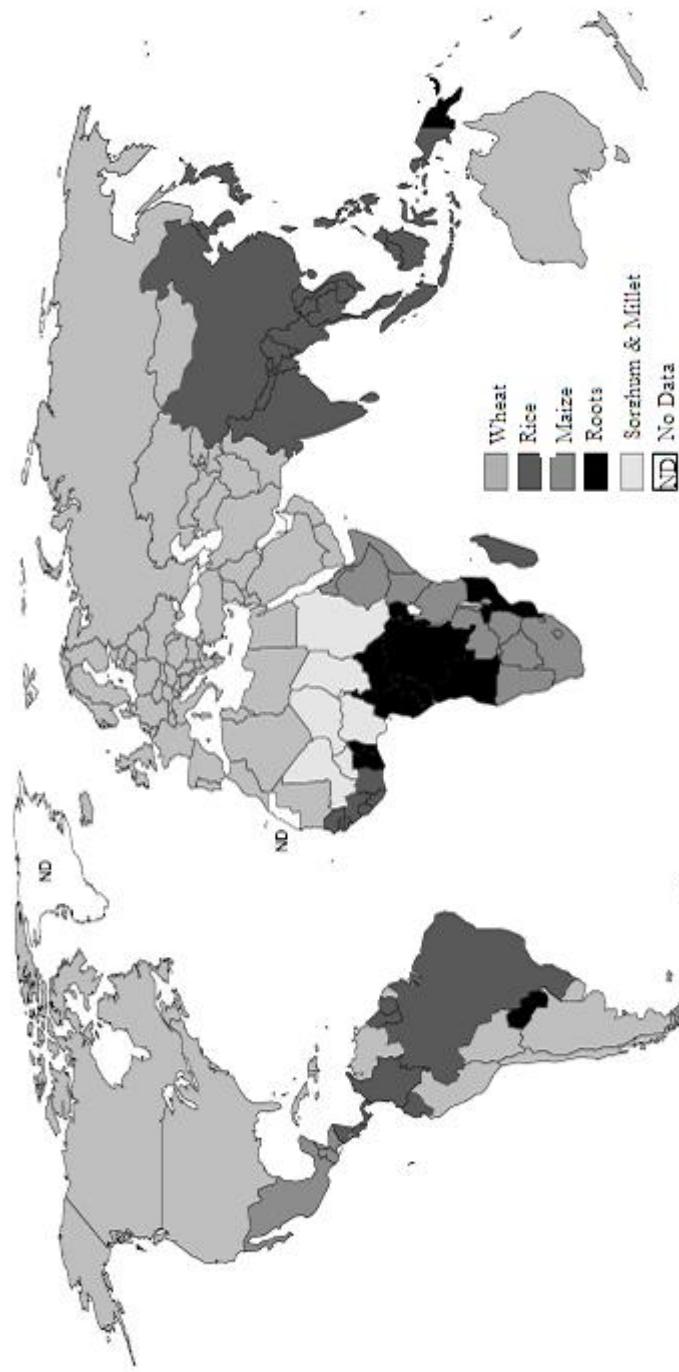

5.3.2 Food Production Zones of Sub-Saharan Africa

Africa can be divided into three food-crop zones linked to agro-ecological, climatic and vegetational zones (Figure 5.2) (FAO, 1997a):

- “The sorghum and millet zone (chickpeas and cowpeas): Sudano-Sahelian region from Mauritania to Somalia;
- The root crop zone (cassava and yams): Guinea-Conakry to the Democratic Republic of Congo (DRC); and
- The maize zone: Kenya, Tanzania, Zambia, Mozambique, Malawi, and Angola to South Africa”.

“Carbohydrates are the single most important source of food energy (calories) in the world” (FAO, 1997a) and in Sub-Saharan Africa they are found in the form of grains and root crops. “Those persons with high carbohydrate diets are often in the lower economic strata as foods high in carbohydrate, such as cereal grains, are most often the least expensive” (FAO, 1997a).

The importance of grain as a source of energy (calories) in Sub-Saharan Africa cannot be underestimated.

Source: FAO (1997a), with permission UN & FAO

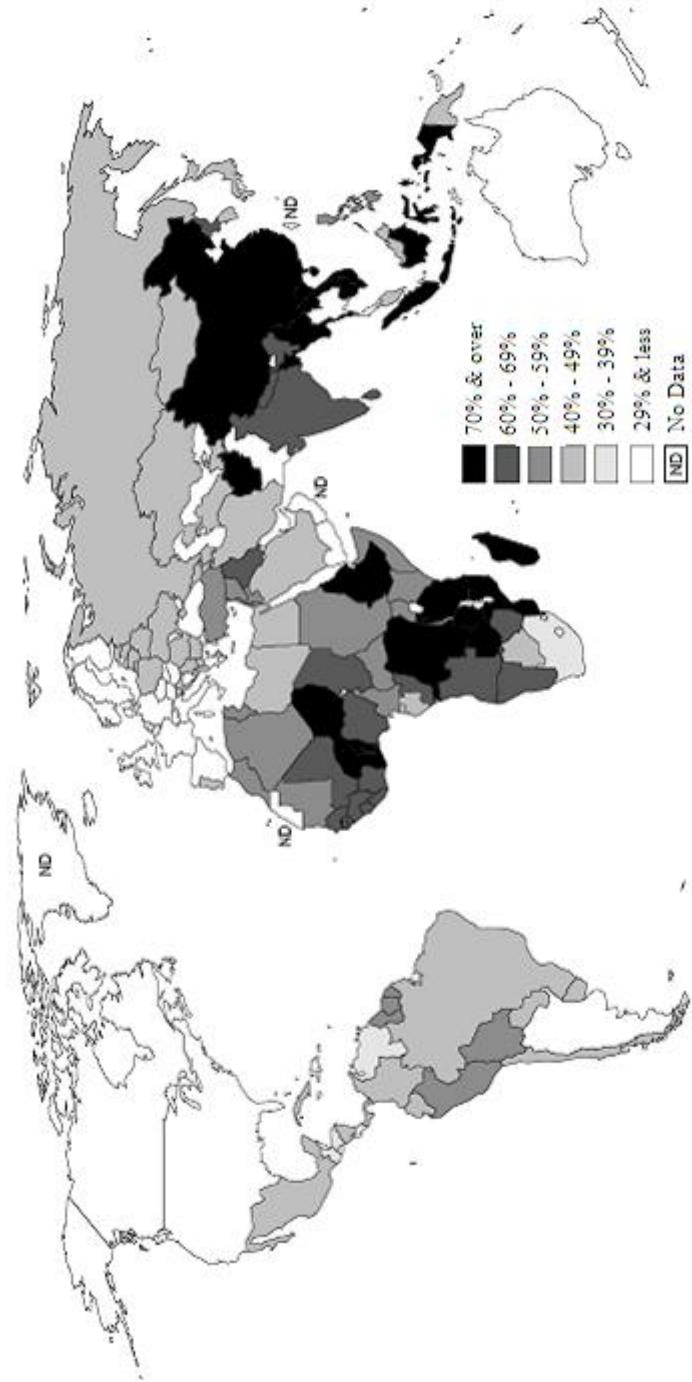

**Figure 5.2: Geography of global grain production,
1990-1992**

“In Africa, people derive 67% (two-thirds) of their calories from less expensive starchy⁵⁰ staples (such as cereals and roots). Only 6% is derived from animal products. In Europe, for example, this percentage is reversed” (Van Wyk, 2000).

FAO (1997a) estimates that Africa and Asia obtain 70% or more of their total calories from grains demonstrating the importance of grains in people’s diets (Figure 5.3). “As a percent of energy (calories), total carbohydrate/starch ranges from about 40% to over 80%, with the developed countries, such as those in North America, Western Europe and Australia at the low end of the range, and developing countries in Asia and Africa at the high end” (FAO, 1997a). Grain deficits in Sub-Saharan Africa are thus a major source of undernourishment. A major problem in Sub-Saharan Africa is that most people’s diets depend upon one major grain, which can also result in malnourishment:

“Carbohydrate foods (in Sub-Saharan Africa – grains and root crops) are an important vehicle for protein, micronutrients and other food components, like phytochemicals, which have important benefits for health. Individual food sources vary, however, in the provision of these components. A single food source of carbohydrate is therefore undesirable and populations whose diets are primarily based on a single food can suffer from micronutrient deficiencies due to lack of variety. It is important, therefore, that a number of different carbohydrate sources be consumed and efforts should be made to encourage a wide variety of carbohydrate foods” (FAO, 1997a).

⁵⁰ Starch is one of three types of carbohydrates called a polysaccharide and is formed of a complex long chain of glucose molecules common in grains and root crops

Source: Griggs (1996, In: FAO (1997a), with permission, Annals of the Association of American Geographers)

Figure 5.3: Percent energy from the dominant starch staples, 1990-1992

In addition, on average only 10 kg of meat/person/year is consumed in Sub-Saharan Africa and by 2030, slow economic growth in Sub-Saharan Africa will limit increases in both meat and dairy consumption (FAO, 2002a). Fish now provide an average of 20% of the protein consumed in Africa; however in Sub-Saharan Africa, fish consumption may stagnate or decline, since wild stocks are almost fully exploited and aquaculture, except in Egypt (not considered as part of Sub-Saharan Africa) is in its infancy (FAO, 2002a).

5.3.3 Food Security in Africa

Food production in Sub-Saharan Africa has in fact increased by over 25% in the last two decades, but not fast enough in terms of per capita production (Roman, 2003). Africa is the only region where average food production per capita has declined over the past 40 years. Since 1970, it has fallen by 15-25%, with imports rising from 8 million tons in 1980 to 12 million tons in 1994. Cereal yields average 1 ton/ha in Africa compared to a global average of 3 tons/ha. (Maxwell, 2001 *In: Devereux & Maxwell, 2001a*). Brown (2003a) estimates in Sub-Saharan Africa that annual grain production per person supplies half the needed calories, the rest coming from meat, milk, eggs and fish. Annual grain intake

“averaged 147 kilograms (per person) between 1961 and 1980, fell to 120 kilograms (per person/per capita) between 2000 and 2002, a drop of 18%. Africa’s ribs are beginning to show. This unfolding food emergency does not exist in a vacuum. Desperate Africans are turning to bushmeat in an effort to survive, threatening various forms of wildlife—from herbivores to gorillas” (see Chapter 10, Section 10.3.4, CITES Cannot Stop the Bushmeat Trade and Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, The Forest People and the *Dobi Dobi*, More Parks And Protected Areas). Efforts to protect wildlife by setting up parks are breaking down as hungry Africans try to survive” (Brown, 2003a).

Average cereal yields in Africa are 50% of those in the other developing regions of Asia, Latin America and the Caribbean. Malnutrition in Africa has remained very high. Food systems have become more vulnerable than before. Food imports and food aid continue to be major issues in terms of food security. Projections are that in Sub-Saharan Africa, annual increases in food production will be lower than increases in food consumption, resulting in a 4-fold (400%) increase in food imports. Sub-Saharan Africa will show little improvement in per capita food production unless population growth can be curbed or the rate of food production significantly increased (Maxwell, 2001 *In: Devereux & Maxwell, 2001a*). Jeffrey Sachs (2005) found the key determinant in whether a country grows economically or not is food productivity, with Sub-Saharan Africa's declining per capita food production being indicative of all its other problems including low soil fertility, low use of fertilizers, limited irrigation, poor road networks, low literacy and high fertility. There will be many hurdles in overcoming the stigma and politics of using genetically modified seeds (e.g., Zimbabwe and Zambia) as a means of increasing food production.

“Africa, which reversed from being a key exporter of agricultural commodities into being a net importer, has the highest percentage of undernourished and has shown the least progress in reducing the prevalence of undernourishment in the last 30 years. Chronic food insecurity now affects some 28% of the population – that is nearly 200 million people who are suffering from malnutrition” (Roman, 2003), implying this refers to Sub-Saharan Africa.

Devereux & Maxwell (2001b *In: Devereux & Maxwell, 2001a*) estimate that there were 840 million undernourished people world-wide in 1992 of which 26% were from Africa. This is up 11% from 1971. FAO (2005) places the percentage of undernourished people in Sub-Saharan Africa as:

<u>Date</u>	1969-71	1979-81	1990-1992	1996-1998	2000-02
<u>%</u>	34	37	35	34	33
<u>Undernourished</u>					

NEPAD (2002) and FAO (2002a) estimate that the number of chronically undernourished people in Sub-Saharan Africa increased from 168 to 194 million between 1990 and 1999 (Table 5.2). Populations in a dry belt extending from the Sahel to the Horn of Africa, and south into East Africa are chronically food insecure (Winterbottom & Neme, 1997). By 2010, the World Bank expects the average per capita caloric intake to be 2,170 calories in Sub-Saharan Africa, compared to 3,470 calories in developed countries (Alemayehu, 2000).

Table 5.2: Population, per capita dietary energy supply and prevalence of undernourishment

Regional Groupings	Total population	Per capita dietary energy supply	Number of people undernourished	Proportion of undernourished in total population			
	1990-92 (millions)	1997-99 (millions)	1990-92 (Calories)	1997-99 (Calories)	1990-92 (millions)	1997-99 (%)	1990-92 (%)
Africa	595.1	710.3	2 322	2 382	173.1	200.1	29
Sub-Saharan Africa	474.5	572.4	2 120	2 190	167.7	194.0	35

Source: NEPAD (2002) with permission, New Partnership for Africa's Development (NEPAD).

It is estimated that by 2009 that 60% of the Sub-Saharan Africa population will consume less than minimum nutritional requirements. It appears that the targets of halving poverty and under-nutrition by 2015 will not be met in Sub-Saharan Africa (Devereux & Maxwell, 2001b *In:* Devereux & Maxwell, 2001a) (see Chapter 13, Section 13.12.3, Role of private sector versus foreign aid in economic development). Maxwell (2001 *In:* Devereux & Maxwell, 2001a) provides the following scenarios for per capita caloric intake in Sub-Saharan Africa (Table 5.3).

Table 5.3: Daily per capita caloric availability from various scenarios for Sub-Saharan Africa, 1990 and 2020

Region	1990		2020 (Calories/person/day)			
	Baseline	Low ^a Population Growth	Low/Investment/ Slow Growth ^b	High Investment/ Rapid Growth ^c	Trade Liberalization ^d	
Sub-Saharan Africa	2,053	2,135	2,219	2,021	2,227	2,093

- a. Low pop growth as determined by United Nations
- b. Simulates combined effect of 25% reduction in non-agricultural income growth rates and reduced investment in agricultural public research and social services
- c. Simulates 25% increase in agricultural income growth and higher investment in agricultural research and social services
- d. Full removal of tariffs and subsidies

Source: Maxwell (2001 *In:* Devereux & Maxwell, 2001a) with permission, ITDG Publishing/University of Natal Press.

Young (2001 *In:* Devereux & Maxwell 2001a) estimates that for a healthy population with a demographic composition typical of Africa, under normal nutritional conditions and environmental temperatures of 20°C, the average caloric requirement is 1,950-2,210 calories⁵¹/person/day for light activity. Women need 1,782 calories/person/day, while older children and adult males might require 2,234 calories/person/day.

Similarly, FAO (2003a) estimates that between 1720-1960 calories/person/day are consumed by adults in developing countries undertaking light activities, anything below this being an indication of undernourishment. FAO (2000b) estimates that depending upon the country undernourishment in Sub-Saharan Africa is indicated by consumption equal to or less than 1,730-1,900 calories/person/day. Baylor College Of Medicine (2004) indicates that the Recommended Daily Allowance (RDA) for sub-adults as 1,300 calories/day for children 1-3 years of age, 1,800-2000 calories/day for children 4-8 years old, 2,000-2,500 calories/day for 6-13 year olds, 2,200 calories/day for girls 14-18 years old and 3,000 calories/day for

⁵¹ Same as kcalories or kilocalories

boys 14-18 years old, though depending on the activity level of the child the RDA could increase or decrease. Smith (1992) suggests that an average minimum daily requirement of 2,200 calories/person/day and 40 gm. protein/person/day would be acceptable for a sample in which 50% of the population is children (e.g., husband, wife, three children and one surviving grandparent).

FAO (2002a) estimates that in Sub-Saharan Africa there is likely to be little or no decline in the numbers of undernourished people, although the proportion will approximately halve. In Sub-Saharan Africa, 15% of the population or 183 million people will still be undernourished by 2030, by far the highest total for any region of the world and only 11 million less than in 1997-99 figure in Table 5.2. This is cause for serious concern.

“Acute food insecurity in 2003 is affecting 38 million people in Africa who are facing the outright risk of famine, with 24,000 dying from hunger daily. Famines are the most visible and extreme manifestation of acute food insecurity. Of the 39 countries worldwide that faced food emergencies at the beginning of 2003, 25 are found in Africa...60% of the World Food Program (WFP)’s work now takes place in Africa” (Roman, 2003).

Madeley (2002) estimates that 18 of the 23 countries in the world facing severe problems feeding their people are African.

In 1995, Sub-Saharan Africa imported 12 million tons of grain, while producing 80 million tons (Maxwell, 2001 *In: Devereux & Maxwell, 2001a*). Imports of cereals by Sub-Saharan countries are estimated at some 17 million tons in 2000, including 2.8 million tons of food aid (NEPAD, 2002). The Commission for Africa estimates that 2002 food imports included US\$ 22 billion worth of food with a food aid complement worth US\$ 1.7 billion in 2002. According to the World Bank projections, Africa will have a food shortage of 250 million tons/year

by 2020 (Mule, 2003). Rosegrant, Paisner, Meijer and Witcover (2001) project a total food deficit of 32 million metric tons/year in Sub-Saharan Africa by 2020 (Table 5.4). The importance of cereals/grains in the diet of Sub-Saharan Africa cannot be over-emphasized. While about 60% of world consumption of coarse grains is used for animal feed, in Sub-Saharan Africa, where food insecurity is very high, 80% of the grain harvest is consumed by humans (FAO, 2002a). Alemayehu (2000) raises the issue that as wheat consumption in Africa grows, displacing more traditional grains/food such as sorghum, millet, maize and cassava, it will be harder to attain food self-sufficiency, as few areas have the climate to grow this crop in substantial quantities.

Table 5.4: Estimated food production, demand and imports, Sub-Saharan Africa, 1997 and 2020

Commodity	1997			2020		
	Production (1000 Metric Tons)	Demand (1000 Metric Tons)	Net Trade (1000 Metric Tons)	Production (1000 Metric Tons)	Demand (1000 Metric Tons)	Net Trade (1000 Metric Tons)
Milk	15,826	18,135	-2,279	33,519	38,115	4,596
Eggs	901	905	-9	1,727	1,723	+4
Roots and Tubers	139,946	139,995	-14	251,959 (307-201)	251,824	+135
Cereals	69,303	82,505	-12,374	128,528 (187-96)	155,872	27,346
Meat	5,407	5,505	-153	10,958	11,252	293
Total Food Imports	-	-	-14,829			32,235

Note: 1) Some differences between production and demand seem to be in error – data left as found in original tables. 2) Numbers in parentheses are highs and lows from optimistic and pessimistic scenarios in million metric tons.

Source: Extracted from Rosegrant, Paisner, Meijer and Witcover (2001) with permission, International Food Policy Research Institute (IFPRI).

It should be noted that while world consumption of roots, tubers and plantain as human food has been on the decline, in 19 countries, all in Sub-Saharan Africa, they provide more than 20-50% of all food energy (FAO, 2002a).

As is discussed later, a major factor in food production in Africa can be related to declining soil fertility. Soil fertility is impacted by a wide range of biological, physical and socio-economic constraints, including nutrient deficiency, inappropriate germ plasm and cropping system design, pests and diseases, poverty, institutional failures, perverse national and global policies with respect to incentives (CIAT, 2002), and over-population.

Norman Borlaug, “father of the Green Revolution”, believes the lack of food production increases in Africa are a major worry and blames: 1) neglect by political leaders, even though agriculture provides the livelihood to a claimed 70-85% of the people in most countries, 2) lowland tropical environments especially the forest and transition areas, which are fragile ecological systems, where deeply weathered, acidic soils lose fertility, 3) shortened or eliminated bush-fallow from expanding populations resulting in nutrient and organic depletion and 4) lack of infrastructure and supply systems (Borlaug, 2000). Mellor (1990a *In: Eicher & Staatz, 1990*) believes that Africa’s agricultural problems can be traced back to the unusually inappropriate national and foreign assistance strategies of the 1970s, resulting in a lack of trained personnel in both agriculture and employment-oriented development strategies, along with horrendous infrastructure and instability in export pricing.

5.4 HUNGER LINKED TO POVERTY

“On September 11, 2001 two planes hijacked by terrorists were deliberately flown into the World Trade Center in New York killing around 3,000 people. The world came to a virtual halt....On September 11, 2001, if that day was an average kind of day, around 16,500 children (world-wide) under the age of 5 died because they were undernourished; their bodies were too weak to survive. That is over 5 times as many as died in New York, and that is just people under the age of 5. The world did not come to a halt, newspapers were not dominated by the tragedy and there was no wave of compassion for the bereaved. And there was no talk of a war on the cause of their deaths, of routing out those responsible. But on the following day, on the 12 September 2001, another 16,500 children under 5 died in similar circumstances. Once again, silence. And the following day, and the day after that...poverty and hunger are fertile breeding grounds for unrest and need to be tackled as part of the battle against terrorism” (Madeley, 2002).

“Weather is partly to blame. But African famine is no accident of the rains; it is mostly man-made, and it is getting worse. The underlying causes are politics, greed, and ignorance – in Africa and elsewhere. Even in the worst affected places, few people go hungry if they are not so poor” (Rosenblum & Williamson, 1987).

In the late 1980s, it became reasonable to focus on food insecurity as the inability of poor countries, poor families and poor individuals to purchase sufficient quantities of food from existing supplies (Mellor, 1990b *In:* Eicher & Staatz, 1990). In the same period, it was also estimated that 100 million people or 20% of Africa’s population did not get enough to eat and 20-30% of Africa’s children were malnourished (Eicher, 1990 *In:* Eicher & Staatz, 1990). UN data show that the proportion of under weight children in Sub-Saharan Africa increased from 26% in 1980 to 28.5% in 2000, which accounting for population increases, in absolute numbers means a rise from 22 million to 38 million children (Devereux & Maxwell, 2001b *In:* Devereux & Maxwell, 2001a). By 2020, this could

amount to between 25.7-32.4% or 43.3 to 54.6 million underweight children under the age of 5 years, respectively in Sub-Saharan Africa (Smith & Haddad, 2000). The 4 million African children that die each year (Rosenblum & Williamson, 1987) can be closely related to mal-/under-nutrition, which makes them more susceptible to disease from immuno-suppression (Sachs, 2005). This problem is not unique to Africa. Poverty, a central cause of malnutrition is deeply entrenched in Africa (Eicher, 1990 *In:* Eicher & Staatz, 1990) (see Chapter 11, Section 11.13.2.1, Child mortality as a health indicator and Chapter 12, Section 12.6.1.1, Increase in poverty and decline in health from structural adjustment).

Hunger and poverty in Africa must be seen as the most urgent and intractable problem facing those concerned with development in the 21st century (Devereux & Maxwell, 2001b *In:* Devereux & Maxwell, 2001a). In addition to food availability and distribution, the single most important cause of hunger is poverty. Thus, access to food is not entirely a matter of availability or need, but rather of wealth. Put another way, hunger is caused not by scarcity but by poverty, a problem that is by no means restricted to Least Developed Countries (LDCs). Questions of hunger and food security are, therefore, questions of poverty (Copeland, 2000; Patel & Delwiche, 2002; Sen, 2002; DFID, 2002; Roman, 2003). Poverty can be defined as spending most of one's income on food or expending most of ones' time producing food for subsistence (Devereux & Maxwell, 2001b *In:* Devereux & Maxwell, 2001a). USAID (2002) estimates that more than 45% of Sub-Saharan Africa's population is now estimated to be in a state of poverty. Palmer and Kline (2003) estimate that:

- More than half of Sub-Saharan Africa's 600 million people still live on less than US\$ 1 a day⁵² [IFAD (2002) and FAO (2002a) define

⁵² Based on "Purchasing Power Parity" where income in local currency is converted to U.S. dollars, and official exchange rate adjusted for cost-of-living differences between the U.S. and country in question, allowing comparison of incomes across countries

“absolute/extreme poverty” or the Poverty Datum Line (PDL) as living on less than US\$ 1/day] (see Chapter 13, Section 13.1 CURRENT STATE OF AFRICAN ECONOMIES and Section 13.12, CAPITALISM WITH A CONSCIENCE).

- More than 28 million Africans are living with HIV/AIDS (Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome), creating 12 million AIDS Orphans to date (see Section 5.8, HIV/AIDS DECLINING AGRICULTURAL PRODUCTION AND FOOD SECURITY IN SUB-SAHARAN AFRICA and Chapter 11, Section 11.13.2.2 HIV/AIDS)
- Forty per cent (40%) of children never go to school in Africa – the only region in the world where the numbers of children out of school are rising (see Chapter 11, Section 11.13.1.1, Educational situation in Sub-Saharan Africa at the beginning of the new millennium

Globally, while there will be a slight reduction in the proportion of people living in absolute/extreme poverty

“only in Sub-Saharan Africa, where incomes are expected to grow very slowly, are the numbers living in poverty expected to rise, from 240 million in 1990 to 345 million in 2015. By then, two out of five (40%) people in the region will be living in poverty” (FAO, 2002a).

It should be noted that since 60-70% of Sub-Saharan Africans are subsistence farmers and pastoralists, growing, and capturing their own food, they are not really as bad off as one might think, but by any analysis, they are poor and their purchasing power in monetary terms is quite limited, though barter and payment in kind helps overcome the lack of hard currency to a very small degree. Additionally, as will be seen over much of rural Sub-Saharan Africa food self-sufficiency is rapidly disappearing resulting in mass migrations from the interior

towards the coastal areas and major urban centers. These countries, however, are ill equipped to deal with this problem, both economically and infrastructurally. As this change in demographics occurs, the next major question is “Who will produce food to feed these urban masses, increasingly living in what some project will become mega-cities”?

“Hunger is particularly damaging to health. It is estimated that nearly half (50%) of all childhood deaths are related to poor nutrition (protein-energy and vitamin A deficiency). And iron-deficiency anemia dramatically increases pregnancy-related mortality” (World Economic Forum, 2004).

According to UN statistics, 529,000 women died of birth related causes in the year 2000, mostly in developing countries of which more than half, namely 270,000, died in Sub-Saharan Africa. In contrast, fewer than 2,500 died in developed countries. In Europe there were 24 maternal deaths per 100,000 live births in the year 2000, while in Africa the average was 920/100,000 live births. The top 12 countries with 1,300 maternal deaths or more/100,000 live births are all in Sub-Saharan Africa and are in, descending order: Rwanda, Sierra Leone, Burundi, Ethiopia, Somalia, Chad, Sudan, the Ivory Coast, Equatorial Guinea, Burkina Faso, Angola and Kenya. Twenty-one Sub-Saharan African countries exceed 1,000 maternal deaths or more per 100,000 live births. Outside Sub-Saharan Africa, only Haiti has more than 1,000 maternal deaths/100,000 live births (*Agence France-Presse*, 2004).

“Poverty is not just a statistic. It is about misery, undernourishment, ill health, lack of education and other basic needs for decent living, shortened life expectancy, and lack of hope. It is about people’s inability to achieve their full potential. It is about missed opportunities. It is a negation of humanity” (Mule, 2003).

Poverty and hunger deprive the world of the creative potential and economic contribution of billions of human beings (Messer & Cohen, 2001). About 90 % of the human brain growth and much of the body's growth takes place in the first five years of life, making nutrition not only a humanitarian imperative but also a basic requirement for sustained economic growth (Rosenblum & Williamson, 1987).

The FAO (2002a) states, “undernourishment can affect brain development in the womb and attentiveness in class, and so is associated with poor educational performance”. “Children that are malnourished experience stunting in their mental and physical development, the effects of which last throughout their lives”,

hunger placing families in an endless cycle, a poverty trap passed on to the next generation, the children of the poor (Short, 2001). Levinson and Bassett (2007) place the critical period of malnutrition as

“especially high during fetal development and during a child's first two years. With children's growth rates, nutritional requirements, and susceptibility to infection at their highest during this time, adverse conditions are more likely to slow growth and cognitive development, and the resulting damage is largely irreversible”.

Alemayehu (2000) raises similar concern over child malnutrition including vulnerability to disease, inadequate physical and intellectual capacities (mental retardation) and low productivity. As things currently stand, Sub-Saharan Africa has lost the race before it gets to the starting blocks in terms of being able to compete in a global market place, as a majority of its population is adversely impacted by poor nutrition. The principal author's mother was a primary school teacher in America during the Great Depression of the 1930s. Skinny little children from poor families could not compete intellectually with better fed youths from middleclass families. These were skinny white children!

There is indisputable evidence that both rich and poor nations are unable to end hunger by simply producing more food and achieving national food self-sufficiency. For example, according to the World Food Program (WFP), there are no shortages of food products in the markets in Lesotho. However, 67% of the population lives below the poverty line and half are classified as destitute. Purchased cereals comprise 75% of annual food needs for Lesotho's poor, and over 70% of the households classified "very poor" in Lesotho have no cereal in reserve. Rapidly escalating prices and vanishing incomes are a lethal combination. The people of Lesotho cannot afford to buy the food that is available (Patel & Delwiche, 2002).

5.5 LAND USE POTENTIAL AND CONSTRAINTS IN SUB-SAHARAN AFRICA

5.5.1 Land Use Potential for Rainfed Agriculture in Africa

Sub-Saharan Africa stands out as the region of the world that is most disadvantaged in terms of unfavorable agro-ecological conditions as well as inadequate transport and communications infrastructure (FAO, 2002a). Estimates of soils in Africa suitable for low-input agriculture (Figure 5.4), implying that large-scale irrigation is absent, use of fertilizers, and pest and weed control is minimal, and soil management does not require high energy mechanized equipment (Eswaran, Almaraz, van den Berg & Reich., 1996) are:

<u>Land Classification for Low-Input Agriculture</u>	<u>% of Land in Africa</u>
Prime	9.6
High Potential	6.7
Medium/Low Potential (Major constraints)	28.3
Desert/Other Unsuitable (Steep land)	55

If one carries the Eswaran, *et al.* (1996) analysis to Sub-Saharan Africa, the following becomes evident:

- Prime/High Potential and Medium/Low Potential lands are just about all in Sub-Saharan Africa (Figure 5.4);
- One can therefore assume that 40% is the Sahara Desert or other deserts north of Sub-Saharan Africa;
- One can assume the 12% Steep Land is in Sub-Saharan Africa (e.g. Mounts Kilimanjaro and Kenya, Rwenzori, Drakensberg, etc.);
- The Namib Desert is the main desert south of the Sahara at 111,147 km² or 0.4 % of the African continent (Jurgens, Burke, Seely & Jacobson, 1997 *In: Cowling, et al., 1997*) – which is insignificant), along with parts of Ethiopia and Somalia;
- One can assume Desert In Sub-Saharan Africa is 55-40-12 = 3%; and
- Just about all the other land is in Sub-Saharan Africa

One can therefore suppose that the following percentages represent Sub-Saharan Africa (Table 5.5):

Table 5.5: An estimate of agricultural land use potential in Sub-Saharan Africa

Land Classification For Low-Input Agriculture	For Entire Continent	% Of Land in Sub-Saharan Africa	Adjusted % For Sub-Saharan Africa Only
Prime	9.6		16.1
High Potential	6.7		11.2
Medium/Low Potential	28.3		47.5
Desert	3.0		5.0
Steep Slope	<u>12.0</u>		<u>20</u>
			99.8 = 100.0

This is a crude estimate, leading one to the conclusion that prime/high potential land for well-managed fallow agriculture makes up about 27% of Sub-Saharan Africa. This compares to 27% of land (596,491,000 ha out of a total of

2,195,958,000 ha or 22 million km²)⁵³ in Sub-Saharan Africa that has “no” or “moderate constraints” for crop production based upon climate, soil and terrain (FAO, 2003b) (Table 5.6), or from 874 million ha (NEPAD, 2002) to 663 million ha (FAO, 2003b)⁵⁴ for all of Africa. Alemayehu (2000) uses an FAO figure indicating 27% of Sub-Saharan Africa is suitable for rain-fed crops. Climate, soil and terrain used by FAO as criteria for determining land suitability for rainfed agriculture are basically the same parameters as used in the above analysis by Eswaran, *et al.* (1996) and Reich, Numbem, Almaraz and Eswaran (2001). Using the above data, it can be estimated that 73% of Sub-Saharan Africa is very poor and/or unsuitable for agriculture as compared to 73% of the land suffering “severe” constraints under the FAO (2003b) classification (Table 5.6).

However, not all of the 27% of the prime/high potential land may be available for agriculture, being in other critical land uses such as parks and protected areas, critical wetlands, forests, or already degraded in over-populated areas such as Rwanda, Burundi, the Highlands of Kenya and Tanzania, southwestern Uganda, Ethiopia and much of Nigeria. As human populations in Africa increase, this is where the battle lines are drawn; what land will remain natural versus be converted to farm land? FAO (2002a) estimates 1,031,000,000 ha in Sub-Saharan Africa as suitable for agriculture. Even if the estimated 31 million ha suitable for irrigation in SUB-SAHARAN AFRICA with environmental constraints (Section 5.12.1.3, Irrigation potential) is added to the FAO estimate in Table 5.6, this would total about 628 million ha implying 39% of this 1.031 million ha of “*arable land*” in SUB-SAHARAN AFRICA would have severe constraints for rainfed agriculture.

⁵³ NEPAD (2002) estimates Sub-Saharan Africa as being 23,621,000 km²

⁵⁴ Global Agro-Ecological Zones (GAEZ). “While representing the most recent global data compilations, the quality and reliability of these data sets is known to be uneven across regions. Especially the quality of the world soil map is reason for concern. It is based on a 1:5,000,000 scale map and it is generally accepted that its reliability may vary considerably between different areas” (FAO, 2003a)

Table 5.6: Climate, soil and terrain constraints to rainfed crop production south of the Sahara

Constraints		Totals

Extracted From: FAO (2003b) with permission, UN & FAO.

Based upon Figure 5.4, it would appear that much of the “prime land” for low input agriculture is also prime commercial land that can be potentially used to feed Africa’s populations using modern technology such as fertilizers, pesticides, drip irrigation, genetically modified organisms (GMOs), etc. This point becomes

critical in planning for Africa to feed itself. This land must be identified and maintained in commercial food production, where possible, to help feed the continent (see Section 5.9.2, Over-Population of Prime Agricultural Land for Low Input Agriculture is also Commercially Viable Land). René Dumont (1966) considers fallow agriculture as a vicious cycle of low-yield agriculture on unfertilized land cultivated by underfed workers, especially in over-populated areas. Low input agriculture, as currently practiced, is a major reason for encroachment on key natural areas and friction between resource users, and can no longer be counted on to feed rural Africa let alone urban centers.

5.5.2 Physical and Environmental Constraints to Overcoming Food Production in Sub-Saharan Africa

A study by Eswaran, Reich and Beinroth, 1997a and Eswaran, Ofori, Mokwunye, Idi-Issa, Ouattara, Sant'Anna and Hoogmoed, 1997b (both *In: Reich, et al., 2001*) showed that 55% of the land area in Africa is unsuitable for agriculture, and that only 11% has high quality soils that can effectively be managed to sustain more than double the continent's current population. According to the World Bank, 80% of Sub-Saharan Africa's soils are fragile and 47% are too dry to support rainfed agriculture (Alemayehu, 2000). Key factors limiting agricultural production in Africa include:

1. **Soil Moisture Stress.** Only about 14% of Africa is relatively free of moisture stress (i.e., 86% of soils suffer from soil moisture stress) (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001); according to another source 67% of soils in Sub-Saharan Africa suffering soil moisture stress (CIAT, 2002). According to the World Bank, 47% of Sub-Saharan Africa's soils are too dry to support rainfed agriculture (Alemayehu, 2000). Moisture stress is not only a function of the low and erratic precipitation but also of

the ability of the soil to hold and release moisture. About 10% of Africa's soils have high to very high Available Water Holding Capacities (AWHC) (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001).

2. **Limited Rainfall.** René Dumont (1966) estimates that between 30° North and South (a line across Africa from about Durban to Cairo), less than 50% of Africa has the adequate rainfall, 800 mm or more, necessary for intensive agriculture. Bond, Child, de la Harpe, Jones, Barnes and Anderson (2004 *In:* Child, 2004) put the crossover point at 700 mm of rainfall between conditions adequate for agriculture versus rangeland.
3. **Hydromorphy** or excess moisture that suppresses aerobic factors in soil building constitutes 8% or 1,904,000 km² of Sub-Saharan Africa (23,621,000 km² total land mass) (NEPAD, 2002).
4. **Phosphorus Fixation.** High free iron content, which is reflected in the red colors of the soil, due to the nature of the parent material or the weathering stage, is employed as an indicator. Phosphorus (P) is immobilized as iron (Fe-) and aluminum (Al-) phosphates in these soils and is thus not readily available for uptake by crops (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001). It is estimated that 4% or 982,000 km² of Sub-Saharan Africa (23,621,000 km² total land mass) suffers from this constraint (NEPAD, 2002).
5. **Nutrient Loss.** It is estimated that 16% or 3,714,000 km² of Sub-Saharan Africa (23,621,000 km² total land mass) is constrained by low nutrient reserves (NEPAD, 2002).
6. **Salinity/Alkalinity.** Soil salinization is the concentration of salts in the surface or near surface of soils. Human induced salinization is a major problem in dry lands and is often associated with large-scale irrigation (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001). This is a major constraint to expanding irrigation over much of the continent (see Section 5.12.1.3, Irrigation potential).

7. **Aluminum Toxicity/Soil Acidification.** Soil acidity and the resultant toxicity of high concentrations of aluminum and manganese in the root zone is a serious problem in sub-humid and humid regions. It is estimated that 4,366,000 km² or 19% of Sub-Saharan Africa's land mass (23,621,000 km²) is confronted with this constraint (NEPAD, 2002).
8. **Soil Depth.** Effective soil depth is a problem in more than 50% of the soils on the Continent and this reduces the potential of the soil for crop production (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001).
9. **Water and Wind Erosion.** Wind and water erosion is extensive in many parts of Africa. Excluding the current deserts, which occupy about 46% of the land mass, about 25 % of Africa's land is prone to water erosion and about 22% to wind erosion – most of this being in Sub-Saharan Africa (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001).
10. **Soil Compaction.** Soil compaction is a worldwide problem, especially with the adoption of mechanized agriculture. It has caused yield reductions of between 40 and 90% in West African countries (Eswaran, *et al.*, 1996; Reich, *et al.*, 2001). This is especially a problem in sandy soils found across much of Africa (Hagedorn, 2003; Hagedorn, *pers. comm.*).

5.5.2.1 Soil moisture stress may be the major constraint to increased agricultural production

“Africa has not had a Green Revolution for the same reason that Australia has not had one: it does not have enough water to use much fertilizer” (Brown, 2003a).

CIAT (2002) estimates 67% of all soils in SUB-SAHARAN AFRICA suffer from soil moisture stress.

Given the marginal soil and rainfall conditions in much of the savanna areas, it was found that in many cases Africans were already optimizing agricultural yields, which could not be substantially increased without costly inputs. The marginal costs of increasing yields are higher than the marginal benefit for the farmer. The foremost factor is the lack of a reliable supply of moisture. Yield increases sufficient to cover the cost of improved seed varieties, fertilizers, and pesticides require a dependable and adequate supply of water. Without water, such investments are more likely to be unprofitable and to result in lower returns than planting the traditional drought-tolerant seed varieties with no purchased inputs (FEWS, 1997). As a result, over much of Sub-Saharan Africa, F₂ generation seeds are planted instead of expensive higher yielding F₁ hybrids produced by seed companies (see Section 5.12.1.2, Green Revolution technologies).

5.5.2.2 Nutrient depletion as a constraint to agricultural production

Africa suffers from geologically induced and inherently low soil fertility as the bedrock consists of mostly granites and gneiss (Nana-Sinkam, 1995). Nutrient loss is an important problem in regions of low-input agriculture, such as in Sub-Saharan Africa. In such regions, when crops are harvested, essential nutrients are taken away in the crop and not replaced (University of Michigan, 2002). Nutrient depletion as a form of land degradation has a severe economic impact at the global scale, especially in Sub-Saharan Africa.

Soil fertility depletion is now known as the fundamental biophysical root cause for declining food security on smallholder farms in Sub-Saharan Africa (Gruhn, *et al.*, 2000).

“Soil degradation indicated by nutrient depletion and loss of organic matter, resulting from erosion and extraction and loss in excess of return, has direct negative influence on agricultural productivity. This may be the single most important constraint to food security in Africa” (NEPAD, 2002).

About 86% of the countries in Africa lose more than 30 kilograms of NPK (Nitrogen, Phosphorous and Potassium)/ha/year (Henao & Baanante, 1999 *In: Gruhn, et al.*, 2000). Estimates in Sub-Saharan Africa indicate a net loss of about 700 kilograms/ha of nitrogen, 100 kilograms/ha of phosphorus, and 450 kilograms of potassium/ha in about 100 million ha of cultivated land over the last 30 years (World Bank, 1996 *In: Gruhn, et al.*, 2000). Henao and Baanante (1999 *In: Gruhn, et al.*, 2000) suggest that nutrient mining may be accelerating. In the more densely populated, semiarid, and Sudano-Sahelian area of Sub-Saharan Africa, net NPK losses have been estimated at between 60 and 100 kg/ha/year. FAO (2002a) cites the loss of NPK as 49 kg/ha/year. Annual depletion rates of soil fertility for Africa were estimated at 22 kg nitrogen (N)/ha/year, 3 kg phosphorus (P)/ha/year, and 15 kg potassium (K)/ha/year (Stoorvogel, Smaling, & Jansen, 1993 *In: Eswaran, Lal & Reich*, 2001).

Stoorvogel, and Smaling (1990 *In: Eswaran, Reich, Almaraz & Zdruli*, 1995) found a progressive depletion of plant nutrients in the cropland soils over a large part of Sub-Saharan Africa where low-input agriculture is practiced. Sanchez and Jama (2002 *In: Vanlauwe, Diels, Singinga & Merckx*, 2002) believe that until soil fertility is addressed, per capita food production in Africa will continue to decrease, this need being analogous to the need for “*Green Revolution*”-type germ plasma in Asia four decades ago. This analogy is supported by the two fathers of the Green Revolution, Norman Borlaug and M.S. Swaminathan (Sanchez & Jama, 2002 *In: Vanlauwe, et al.*, 2002).

Of this soil degradation, Oldeman, 1992 and Oldeman, Hakkeling and Sombrek, 1991 (both *In: Gruhn, et al., 2000*) estimate the following degree of nutrient-related soil degradation and the main causes, all of which can be linked to over-population of people and their livestock (Table 5.7). Insecure land tenure is believed to be another reason for minimal investment in long-term soil productivity (Gruhn, *et al.*, 2000) (see Section 5.7.1, Property Rights and Land Tenure, Constraints to Soil Fertility and Agricultural Production). Based upon Oldeman, van Engelen and Pulles (1990 *In: Barbier, 1998*) and WRI (1992 *In: Barbier, 1998*), it is estimated that between 1945 and 1990 there was 494.2 million ha of human-induced soil/land degradation in Africa of which 320.6 million ha were classified as moderate/severe/extreme degradation and 173.6 million ha as light degradation. This amounted to 25% of the world's degraded lands. Also about 22% of the 494.2 million ha of degraded land was vegetated. The amount of degraded land would be significantly higher in 2005 from population and livestock increases, along with a general failure to intensify traditional extensive management systems in a sustainable manner.

Table 5.7: Extent and causes of declining soil fertility in Africa

Region	Extent of Human-Induced Nutrient-Related Soil Degradation (Millions of Ha)				
	Light	Moderate	Severer		
Africa	20.4	18.8	6.6		
Asia	4.6	9.0	1.0		
South America	24.5	31.1	12.6		
Human-Induced Causes of Soil Degradation (Percent)					
	Deforestation	Over-exploitation	Over-grazing	Agricultural Activities	Industrial Activities
Africa	13.6	12.8	49.2	24.5	----
Asia	39.9	6.2	26.4	27.3	0.1
South America	41.0	4.9	27.9	26.2	----
World	29.5	6.8	34.5	28.1	1.2

Note: Over-Exploitation is for fuel wood

Source: Oldeman (1992 *In: Gruhn, et al., 2000*) with permission, International Food Policy Research Institute (IFPRI).

Despite the cumulative effect of negative nutrient balances, overall yields in Africa have increased. From 1960 to the mid-1990s, wheat yields more than doubled from 0.7 to 1.8 metric tons/ha, while maize yields rose from 1.0 to 1.7 metric tons/ha (FAO various years). Together with the limited adoption of new technologies, the mobility of the Sub-Saharan Africa farmer has been a major factor in the improvement of production, albeit at the cost of soil degradation. Between 1973 and 1988, arable and cropped land increased by 14 million ha in Sub-Saharan Africa, while forest and woodland areas fell by 40 million ha, and pasture land remained stable. Thus, 26 million ha (the difference in total land use) have been lost to desertification or abandoned (Gruhn, *et al.*, 2000). Likewise, FAO (2002a) estimates that from 1961-1999 in Sub-Saharan Africa land expansion accounted for 35% of increases in crop production. “Desertification refers to land degradation in arid, semi-arid, and sub-humid areas due to anthropogenic activities” (UNEP, 1993; Darkoh, 1995 both *In: Eswaran, et al.*, 2001).

The effect of reduced soil fertility remains generally hidden because farmers abandon nutrient-depleted land to clear and farm uncultivated, marginal land (Gruhn, *et al.*, 2000). The question is how much more marginal land remains, and how much of this marginal land is critical for other uses such as wildlife, forestry, grazing, watershed protection, etc.? For instance in the Benin section of “W” National Park, tens of thousands of cattle invade the park each dry season since expanding agriculture excludes herders from former pastoral land on the park’s periphery (East, 2005). This is happening across the subcontinent. As people move onto land that is “marginal for agriculture”, they are moving onto land important for other uses, particularly conservation, and are thereby risking to create major conflicts for instance between small-scale farmers and pastoralists as has been happening in Kenya for the past 10-15 years (see Section 5.7.1.3, Improperly planned land tenure; impacts on wildlife, conflicts between

pastoralists and small-scale farmers, Amboseli and Maasai Mara and Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY). The cost of eliminating this nutrient depletion in Africa by using fertilizer would amount to US\$ 1.5 billion per year (Henao & Baanante, 1999 *In: Pinstrup, et al., 1999*)

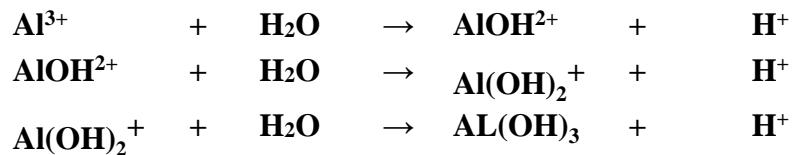

Dudal (2002 *In: Vanlauwe, et al., 2002*) also suggests that between 1986 and 1996, cereal production increased by 20-100% in 39 of 48 Sub-Saharan countries, showing that in addition to nutrient depletion issues, other factors such as new crops and stress-tolerant varieties may be just as important to increasing production and taking pressure off extensions into natural systems.

5.5.2.3 Nutrients, pH, acidity and carrying capacity

Cation Exchange Capacity (CEC) is the sum total of exchangeable cations (element with a positive electrical charge) that a soil can absorb, with a high cation exchange linked to increasing nutrient availability. Without negatively charged soils, soils would not retain cations and plant life as we know it would have a tough time existing. The ability of a soil to absorb and exchange nutrient cations is mainly derived from organic matter and clay minerals.

The relative size of soil particles from largest to smallest is: sand > silt > clay. Very fine soils like clays have a high CEC, whereas larger-textured sands have a low CEC. So many properties of the soil depend on the particle sizes of the soil, such as water holding capacity, nutrient holding capacity, carbon accumulation, and CEC. Soils which restrict water penetration to the topmost 20-30 cm (e.g. clay) are the most beneficial to grass cover (Smith, 1992).

Retention of nutrients is also closely related to soil pH. pH is a measure of the hydrogen ion activity in soil and water. It is mathematically related to hydrogen ion activity according to the expression $\text{pH} = -\log_{10} [\text{H}^+]$, where $[\text{H}^+]$ is the hydrogen ion activity. pH tends to correlate to acidity, the lower the pH the higher the acidity (USEPA, 1976). It can be measured electrometrically or colorimetrically (APHA, 1976). pH is an important factor in the chemical and biological systems of soil and water. The main cations in soil that cause acidity are H^+ and Al^{3+} . They are called “acid cations” because they tend to lower the pH of soil solutions. Once displaced by increasing acidity, aluminum ions can hydrolyze (i.e. split water), release H^+ , and further lower the pH increasing acidity (Carleton College, 2005):

Loss of organic cover from cultivation, over-grazing and resulting wind and rain erosion can result in a loss of buffering capacity setting up this chain reaction. Soils are acidic for several reasons:

- Their parent materials were acidic and relatively low in base cations (Ca^{2+} , Mg^{+2} , K^+ , Na^+), which tend to exist in compounds that raise the pH of soil solutions by neutralizing H^+ ;
- These elements have been removed from the soil profile by normal leaching from rainfall and harvesting of crops. Given other parameters as constants, as rainfall increases nutrient leaching tends to increase, resulting in grasses with lower protein content (Hagedorn, *pers. comm.*);
- Organic acids also contribute to acidity, especially in forested soils;

- Leaching of Al from the mineral soil crystalline lattice or exchangeable Al^{3+} on the soil surface; and
- The presence of exchangeable H⁺, such as from acid rain.

Soil acidity is a major growth-limiting factor for plants, and aluminum toxicity is often the main cause of acid-soil infertility. Sometimes, farmers mistake low crop growth and yield to a lack of nutrients when soil acidity is really the culprit. As the soil becomes too acidic or too alkaline, key nutrients become unavailable for uptake by grasses and/or crops (Hartmann, Kofranek, Rubatzkym & Flocker, 1988). For instance at pH's below 5, phosphates (H_2PO_4^- or HPO_4^{2-}) react with aluminum (Al^{3+}), iron (Fe^{2+}) and manganese (Mn^{2+}) to form insoluble hydroxyl phosphates making P unavailable to plants. As the pH rises above 7, phosphates react with calcium (Ca^{+2}) and magnesium (Mg^{+2}) to also form insoluble di-and tri-calcium and di and tri-magnesium phosphates also unavailable to plants. Thus at a pH between 6 and 7 the fixation of phosphates is minimal, maximizing its availability to uptake by plants. Nitrogen and sulphur become increasingly available from pH 4-5.5, after which they remain equally available regardless of pH (DAM, 2003). This impacts not only the productivity of the grasses, but the nutrient quality of the grasses for consumption. For example according to Smith (1992):

- Soils derived from volcanic rock (e.g., black cotton soils) such as the Serengeti Plains and Maasai Steppe in East Africa have a high cation exchange and can support a large herbivore biomass – resulting in low mobility required of wildlife and/or livestock;
- Soils derived from metamorphic substrates such as southern Tanzania, and Malawi have a lower nutritional status as well as certain trace element deficiencies (e.g., Miombo/*Brachystegia* spp. woodland savanna of Malawi is deficient in phosphates and calcium, therefore restricting pastoral use).

This can result in cattle eating dried bone from carcasses and dying from botulism poisoning. On the other hand, it may be acceptable to certain wildlife (e.g., Nyika Plateau, Malawi supporting reedbuck – *Redunca arundinum arundinum*);

- Soils of Zambia's savannas are generally nutrient deficient, producing the extensive grasslands of *Hyparrhenia spp.* and *Trichopteryx spp.*. The one exception is the Batoka Highlands on doleritic bedrock which is more productive;
- Soils of the Highveld of South Africa in Northern Transvaal (e.g., portions of the Limpopo, Gauteng and Northwest Provinces) and the Free State have a low nutrient status requiring considerable mobility by traditional pastoralists. Permanent grazing with modern fencing has resulted in tremendous bush encroachment; and
- Fynbos of the Western Cape, South Africa is deficient in cobalt producing anemia in herbivores. This traditionally required greater mobility by Khoikhoi herders to maintain herd quality and milk production.

“The Sahel zone of West Africa is particularly covered with sandy acidic soils with low buffering capacities” (CIAT, 2002).

Game is less sensitive to phosphate deficiencies than livestock, probably due to the fact that wild animals are better able to use natural salt licks and are also better able to select plant material of high nutritional value (Bothma, 1989). Today, nutrient deficiencies can be addressed with mineral and salt licks.

5.6 LAND DEGRADATION

Land degradation will remain an important global issue for the 21st century because of its adverse impact on agronomic productivity, the environment, and its

effect on food security and the quality of life (Table 5.8) (Dregne & Chou, 1994 *In: Eswaran, et al.*, 2001). According to Eswaran, *et al.* (2001) the compilers of Table 5.8, Dregne and Chou (1994), covered only dry areas, including rangelands. This would account for the reason why only 14 million km² is given as a total area for the African continent as opposed to the actual estimated area, which is between 29.8 million km² (Reich, *et al.*, 2001) and 30.3 million km² (Clark, Church, Davies, Hilling, Kenworth, McMaster, Stevens, Thorp & Turay, 1975).

Table 5.8: Estimates of all degraded lands (in million km²) in dry areas from unsustainable agricultural and landuse practices

Continent	Total area (km ²)	Degraded area † (km ²)	% Degraded
Africa (Dry Areas)	14.326	10.458	73
Asia	18.814	13.417	71
Australia and the Pacific	7.012	3.759	54
Europe	1.456	0.943	65
North America	5.782	4.286	74
South America	4.207	3.058	73
Total	51.597	35.922	70

† Comprises land and vegetation

Note: In Africa, desert and steep slopes, where agriculture is not considered possible except in limited areas (oases), do not appear to have been considered since they are not considered as agricultural lands. Likewise, high rainfall areas such as the Congo Basin would not have been considered.

Source: Dregne and Chou (1994) *In: Eswaran, et al.* (2001) with permission, International Center for Arid and Semi-arid Land Studies (ICASALS).

GLASOD⁵⁵ (1987) provides the following estimates of total land degradation (Table 5.9), 42% of Sub-Saharan Africa suffering from moderate to severe soil

⁵⁵ “UNEP’s (United Nations Environmental Program) recommendation led to the publication of a world map on the status of human-induced soil degradation at a scale of 1:10 million. This map is based on input from more than 250 scientists on soil degradation in the 21 regions into which the world was divided for analytical purposes. UNEP’s immediate objective in producing the map was to help decision- and policy- makers better understand the dangers of inappropriate land and soil management. GLASOD (Global Assessment of Soil Degradation) is criticized today as inaccurate, subjective, and not appropriate for assessing soil degradation at the country-level. Despite these drawbacks, it remains the only database to define the status of human-induced soil degradation and the extent of desertification at the global scale” (WRI, 2004).

degradation. Since this analysis was undertaken in 1987, about 18 years ago, it can be assumed that the level of degradation has increased significantly under low-input regimes (e.g., low amounts of fertilizer use) as fallow periods disappear and farmers move into more marginal areas.

Table 5.9: Land degradation severity by percent severity class

	None	Light	Moderate	Severe	Very Severe	Total Degradation: Light To Very Severe	Degradation: Moderate To Severe
Sub-Saharan Africa	33	24	18	15	10	65	42
North Africa & Near East	30	17	19	28	7	70	52
Asia & Pacific	28	12	32	22	7	72	61
North Asia. East of Urals	53	14	12	17	4	47	33
South & Central America	23	27	23	22	5	77	50
Europe	9	21	22	36	12	90	70
North America	51	16	16	16	0	44	29
World	35	18	21	20	6	65	47

Source: GLASOD (1987) with permission, UN & FAO.

About two-thirds (67%) of the world's agro-ecosystem has been degraded during the last 50 years (GEF, 2002). "Land degradation can be considered in terms of the loss of actual or potential productivity or utility as a result of natural or anthropogenic factors; it is the decline in land quality or reduction in its productivity" (Eswaran, *et al.*, 2001). Oldeman, *et al.* (1991 *In:* Eswaran, Beinroth & Reich, 1999a) suggest that about 17% of the global land area is degraded by human interventions. The consequences of land degradation not only affect the performance of the land for food and fiber production, but also have grave consequences for the environment, including biodiversity.

“Africa's natural resources are rapidly being degraded because the required increased production is being derived from extensification because markets are not rewarding intensive management. This degradation is manifested most noticeably in deforestation, genetic erosion and soil degradation, and particularly loss of organic matter, under agricultural and pastoral use. This degradation influences many other resources and environmental services of importance to sustainable development. It leads to serious distortions in the hydrological balance, impaired access to water resources, continuing loss of plant genetic resources and encouragement of noxious weed (often exotic invasives) populations. In extreme cases, the loss is irreversible, resulting in the extinction of races of precious indigenous food crops and other useful plants. It is estimated that about 0.7% of forests in Africa are lost each year. Degradation of cropland is severe in Africa, affecting more than 65% of cropped area. Degradation of pastureland is also severe, affecting 31%. The loss to the continent's economy from these sources is incalculable” (NEPAD, 2002).

According to other accounts, 72% of African arable land has already been degraded as a result of soil erosion (Naseem & Kelly, 1999). The United Nations (Hawley, 2004) projects that by 2025, 67% of the arable land in Africa will disappear. The two areas of Africa that are extremely vulnerable to soil erosion are (de Vos, 1975):

- The “tropical belt” (“tropical savanna” or “summer rainfall climate” including most of Mali, Niger, Nigeria, Chad, Ghana, Togo, Guinea-Conakry, Cameroon, RCA, southern Sudan, Tanzania, Uganda, Kenya, DRC, Zambia, Mozambique, Zimbabwe and a portion of South Africa, where the clearing of vegetation exposes the soil to torrential rain and the leaching of nutrients. During the dry season wind erosion and/or baking of the soil takes place so plants cannot push through.
- The “arid belt”, the desert to the north and in Sub-Saharan Africa, the Sahel from Senegal across to Sudan, where daily temperatures are extreme

and commonly rise above 38° C. There is also a lack of soil humus and poor soil texture. Through evapotranspiration and osmoregulation, salts are brought to the surface of soils, making irrigation and the mitigation of this problem very expensive and in many cases uneconomical.

Where poor soil conservation and management methods prevail, long-term productivity is projected to decline substantially unless soil management practices improve. In Africa (Dregne, 1990; Lal, 1991 both *In: Gruhn, et al., 2000*) and Asia (Dregne, 1992 *In: Gruhn, et al., 2000*), past erosion has reportedly reduced average crop yields (per ha)⁵⁶ by 10 to 20% over the past 100 years. If erosion at this rate continues unabated, crop yields may decrease by another 16.5% in Asia and 14.5% in Sub-Saharan Africa by 2020 (Scherr & Yadav, 1996 *In: Gruhn, et al., 2000*). “Yield reduction in Africa (Lal, 1995 *In: Eswaran, et al., 1999a*) due to past soil erosion may range from 2 to 40%, with a mean loss of 8.2% for the continent. If accelerated erosion continues unabated, yield reductions by 2020 may be 16.5%. Annual reduction in total production for 1989 due to accelerated erosion was -8.2 million tons for cereals, -9.2 million tons for roots and tubers, and -0.6 million tons for pulses” (Eswaran, *et al.*, 1999a).

The main causes for degradation are 1) increased demand for food for a rapidly growing population; resulting in intensification of agriculture and shortened fallow periods without appropriate inputs; 2) inappropriate agricultural policies such as subsidies for water, fertilizers, and other agrochemicals, leading to wasteful use; 3) use of agricultural machinery and agronomic practices that are unsuitable for local soil and water conditions as well as the social and economic situation; and 4) in arid and semi-arid areas, a high concentration of livestock, leading to over-grazing. The adverse impacts of land use and land use change

⁵⁶ Note: Food production in Sub-Saharan Africa increased by 25 % in the last two decades (see Section 5.3.3, Food Security in Africa), though this is different than yield, with increases in food production coming from extensification into marginal agricultural areas, which may serve as key centers of biodiversity.

include soil degradation-erosion, salinization, nutrient depletion, chemical pollution, and the loss of biodiversity, especially biodiversity of importance to agriculture (GEF, 2002). Some believe that it is impossible to have environmentally sound resource management under conditions of high population growth, scarce resources and the absence of alternatives to subsistence agriculture (Moorehead & Wolmer 2001 *In:* Devereux & Maxwell, 2001a).

In the context of productivity, land degradation results from a mismatch between land quality and land use. Mechanisms that initiate land degradation include physical, chemical and biological processes. Soil structure is the important property that affects all three degradative processes. However, land degradation as a biophysical process driven by socioeconomic (e.g. land tenure, marketing, institutional support, income and human health) and political causes (e.g. incentives, political stability) (Eswaran, *et al.*, 2001) may be just as important an incentive or disincentive to sustainable resource management and a cause for declining food production (see Section 5.7, POLICY REFORM CONSTRAINTS TO AGRICULTURAL PRODUCTION). Virmani, Katyal, Eswaran and Abrol (1994 *In:* Reich, *et al.*, 2001) also identify other causes for land degradation, such as drought, failure to implement appropriate technologies, poverty, constraints imposed by recent international trading agreements, and local agricultural and land use policies. For instance, in western Kenya, resource-poor households, compared to wealthy ones, made only 5% of the farm investments, had over twice the erosion rates and 28% of the maize yields. These resource-poor households constitute 90% of the population (CIAT, 2002). Government land tenure policies are especially important, taking common property managed at the local level by the chief and elders to open access property owned and handed out by government, often promoting failed large-scale government irrigation parastatals at the expense of traditional farmers and/or commercial farmers.

Losses from soil degradation are not unique to Africa, “It is estimated that the total annual cost of erosion from agriculture in the USA is about \$US 44 billion/year, about \$US 247/ha of cropland and pasture” (Eswaran, *et al.*, 1999a). In the soil conservation conscious United States, an estimated 1.3 billions tons of soil are lost each year along with associated fertilizers and pesticides. The declines in soil erosion in America over the last 60 years have primarily been due to the creation of local soil and water conservation districts to educate farmers in how to reduce erosion and protect streams, taking the most vulnerable lands out of production. This loss of soil along with expanding urban populations in the U.S. will decrease the land available for food, while overall populations increase. This will increase the need for soil conservation efforts giving incentive payments to farmers who adopt corrective measures. This approach is thus one of conservation through subsidization (Mast, 2003), which World Bank/IMF structural adjustment programs dissuade in Sub-Saharan Africa (see Chapter 12).

5.6.1 Colonialism and its Impact on Land/Soil Degradation and Agriculture in Sub-Saharan Africa

“In South Africa few white men have either the time, the patience, the understanding or the sympathy even to attempt to regard things from the native’s point of view, and this failure is the source of a general popular misunderstanding of his character and temperament...Recent experiences in South Africa (brain capacity and mental level) do not support this assertion, for it has there been deemed necessary to limit strictly the industrial native’s sphere of labor” (Stevenson-Hamilton, 1929).

Prior to colonialism, low human populations practiced extensive fallow agriculture and nomadism, ecologically controlling their landscape to suit their needs (e.g., pushing back the bush and the tsetse fly in favor of grasslands, fallow

agriculture, etc.) (see Chapter 2, Section 2.3.3, Fallow Agriculture in Low Productive Areas).

This changed by the mid-19th century with the arrival of European powers in Africa. Colonial agricultural policy makers were convinced that the main problem of the African agricultural system and a major limiting factor to increasing agricultural production was the customary land tenure system. Customary tenure was blamed for the lack of interest and lack of attention given to land conservation and improvement issues, the lack of security to investors in the agricultural sector, and the difficulty of obtaining credit since land could not be mortgaged (Tonah, 2002).

East and Southern Africa tended to become settler colonies which displaced indigenous farmers to “homelands and reservations” (IFAD, 2002), while West and Central Francophone Africa co-opted traditional leaders into using their constituents to produce cash crops while maintaining indigenous institutions and land tenure systems (IFAD, 2001).

The colonial powers forced rural populations to produce cash crops through imposed taxes. Cotton, coffee, cotton wool, rubber, etc. were sold at set prices to the colonial powers. In East and Southern Africa, colonial governments established mechanisms to assist European settlers (the high point of whose influx was often after World War II). They also provided incentives for production, through pricing policies and monopoly control of most farm commodities, whether for export or for domestic trade. African farmers were often debarred from using the legal marketing channels and had to sell whatever surplus they had to nearby large-scale (European) farmers or the informal market, but always at lower prices (IFAD, 2002).

Very often, lacking a clear understanding of soil ecology and carrying capacity, European interventions resulted in environmental degradation that the African people had not known. “ ‘But here in Africa it (cash crops) has destroyed the land, it has destroyed the people, it has destroyed the future for very short-term and long-term benefits’ ” (Robert Ndaw, former Malian minister directing the UN Environmental Program’s Desertification Center in an interview with the BBC in 1986 *In: Rosenblum & Williamson, 1987*).

These and other interventions resulted in: 1) land compression from Africans being squeezed into smaller eventually unsustainable areas (e.g., tribal trust lands, communal areas, or Bantustans) in favor of large privately owned European plantations and national parks/game reserves, turning farmers into manual laborers on the plantations or in mines, etc. (see Chapter 3, Section 3.1.7, Colonial Economies and Section 3.4.1.2, Centralization of control over wildlife, South African Republic) 2) the introduction of industrial mono-culture plantations (peanuts, palm oil, rubber, coffee, tea, sugar cane, tobacco, banana, timber, etc.) and cash crop economies to replace traditional food production. This adversely impacted on the nutrition of rural Africans, and 3) improved animal husbandry resulting in an explosion of livestock combined with the slow elimination of nomadism. This took extensive pastoralists into intensive management systems for which they were technically ill prepared (see Chapter 6). The dual system of colonial paternalism and *laissez-faire* private enterprise ended Africa as a “Garden of Eden” and resulted in a rapid deterioration of the land and, to some extent, the whole structure of society (de Vos, 1975; Martin & O’Meara, 1995; IFAD, 2002; Madeley, 2002; Tonah, 2002).

Raw agricultural products (e.g., coffee, cocoa, tobacco, tea, etc.) were then sent to the home country where the “added value of transformation” was obtained, and often sold back to the producing country at a higher price. This is one reason for

the extremely low level of development in many Least Developed Countries (LDCs), particularly African countries, most of which only gained their independence in the last 40-50 years (Copeland, 2000).

When black leaders came to power in the 1950s and 60s, the system was firmly in place. Cash crops became the cornerstone of African agriculture, and peasant farmers – still nearly 70% of the population – were seen as a sign of all that was wrong with African farming; technically backward, unsophisticated and unproductive (Elwood, 1984). Policies of post-independence governments in the region generally continued the bias against smallholder agriculture. They used the marketing and control systems (e.g., coffee and livestock marketing boards) they had inherited to purchase export crops from farmers at low prices and sell them at higher world market prices, allowing corrupt officials and politicians to line their pockets. In many countries, the government also controlled the marketing of food for the population. This allowed them to keep urban food prices artificially low in the interests of cheap labor, and to maintain peace and quiet in the cities and towns where political pressures were more likely to form (IFAD, 2002). All of this was to the detriment of the small-scale farmer.

In many ways, a contemporary map of Africa remains a colonial map with little relation to indigenous concepts of space (e.g., ethnic areas such as the Maasai, which now straddle two countries, or traditional kingdoms, which were destroyed). Most present-day urban centers and transportation systems were designed with colonial objectives, namely the development of efficient economic exploitation as part of an export-oriented primary producing economy to supply raw materials and agricultural products (Martin & O'Meara, 1995) for added value in the West, but with little opportunity for internal circulation of goods or people.

5.6.1.1 Impacts of colonialism on agriculture and pastoralism in the Sahel

The Sahel forms a broad band stretching across West Africa between the rainfall isohyets of 200 mm to 400 mm/year (see Chapter 1, Figure 1.3: The Sahel).

“Non-irrigated agriculture in the Sahel is only possible in areas where the length of the growing season allows crop maturation. The lack of water, in association with high temperatures (up to 45°C at certain periods of the year), is the most limiting factor for agricultural productivity in the region. Rainfed and recessional (floodplain) agriculture are the dominant practices. In the arid zone, millet and sorghum are cultivated near water points. In the semi-arid zone, the important food crops are millet, sorghum, cowpeas and maize. Sorghum predominates in the heavier soils and millet in the sandy soils” (Moore, Bertelsen, Diarra, Kodio, Cissé & Wyeth, 2000) (see Chapter 1, Table 1.1).

The first chapter of this book, which deals with ancient Sahelian civilizations, has shown that desertification was already occurring in the Sahel, in the 15th and 16th centuries because of human mismanagement of resources. It can be argued that colonialism helped accelerate this process.

Hardin (1977) attributes acceleration of the physical destruction of the Sahel to the loss of political power and control over natural resources by the Sahelian peoples under French colonization during the late 19th century. West African civil society was suppressed by a highly centralized formal regime instituted under colonialism that has largely been maintained under nearly 40 years of independence. This highly centralized structure dominated customary local governance, constraining it to the village arena (Moore, *et al.*, 2000).

While one cannot blame the collapse of the integrated social and ecological system solely on Western interventions, few of these have favored the local inhabitants of the Sahel. Such interventions resulted in destructive practices from the cumulative effects of over-population, deteriorating climatic and soil conditions, and, above all, the adverse impact of Western economic and social systems imposed upon Africa (Hardin, 1977).

“It has been the West's deliberate attempts to do well that seem to have caused the most harm. The West in this case means the French, up until 1960, when the Sahelian countries were granted independence, and the French, Americans, and others thereafter. The French should probably not be held particularly to blame; they were only following conventional wisdom, and there is little reason to believe that other donor countries would have handled the situation very differently...Introduction of a cash economy by the French to earn foreign exchange had profound effects on the traditional system. At the same time, the population increase led to more and more people trying to farm the land. With the best lands given up to the cultivation of cotton and peanuts, people had to bring the more marginal lands into use to grow their own food crops. In many cases these ecologically fragile zones could not take the strain of intensive agriculture. The usual process is that the fallow periods of 15 to 20 years are reduced to five or even one. Fertility declines, slowly at first, and then in a vicious spiral. Poor crops leave the soil exposed to sun and wind. The soil starts to lose its structure. The rain, when it falls, is not absorbed but runs off uselessly in gullies” (Hardin, 1977).

Little emphasis was placed on improving agricultural production of food crops as a means of improving nutrition, or on the development of industries (Dumont, 1966), especially those linked to transforming agricultural produce on the continent that would have stimulated African economies.

The Sahel enjoys only about four months of rainfall a year. Traditionally, the grasses were sufficient to support herds of cattle tended by nomads (e.g. Fulani, Tuareg, etc.), and in the southern regions, the cultivation of millet and sorghum, together with cash crops such as peanuts and cotton took place. By 1970, just before the collapse of agriculture brought on by a major drought, the fragile steppe and savanna ecology of the six Sahelian countries (Senegal, Mauritania, Mali, Burkina Faso, Niger and Chad – see Chapter 1, Figure 1.3: The Sahel) was supporting some 24 million people and about the same number of animals. This burden amounted to roughly 33% (a third) more people and twice as many animals as the land was carrying forty years before in the 1930s (Hardin, 1977). To this, one could add Gambia, the Sahelian parts of Nigeria, Cameroon, Chad, the Central African Republic and Sudan.

“If the nomads could have been persuaded to kill more of their cattle for market, the animal population might have been kept within bounds. Not foreseen was the fact that cattle are the nomads' only means for saving, and it in fact makes good sense -- on an individual basis -- for a nomad to keep as many cattle on the hoof as he can. As a result herd numbers increased hand over fist in the decade following independence, aided by 7 years of unusually heavy rains; from about 18 to 25 million between 1960 and 1971. The optimum number, according to the World Bank, is 15 million...The French colonial division of the Sahel into separate states has also faced the nomadic tribes with national governments which have tried to settle them, tax them, and reduce their freedom of movement by preventing passage across state boundaries” (Hardin, 1977);

this freedom of movement being necessary to assure the sustainable use of the Sahel's grasslands. Increasing numbers of Nomadic herders in the Sahel region, ever more impoverished because of drought and the expansion of arable agriculture, have been forced to graze their herds on fragile grasslands.

“Mobility has given way to more permanent cultivation and restrictions on animal movements. Due to the scarcity of unused arable land, farmers have reduced or eliminated fallow periods and extended cultivation into marginal areas that had been reserved for pastures and forests. The resulting loss of pasture and firewood has led farmers to use their crop residues for animal feed and cooking, and as the trees, bushes, and crop residues that helped to anchor the soils have been depleted, wind and water erosion have carried away topsoil” (FEWS, 1997).

In some cases, crop residues have been used as a source of fuel, no longer being available as dry season fodder for livestock. In Sub-Saharan Africa, excluding South Africa (14% traditional fuels), traditional fuels (e.g., crop residue, dung, charcoal and firewood) account for over 60% of primary fuel⁵⁷ used and may be as high as 70% in Sudan and 90% in countries like Burundi and Burkina Faso (Sokona, 2002).

“...in many areas wood-fuel resources are under severe pressure, a fact reflected in the growing use of inefficient and unhealthy non-woody biomass resources such as animal wastes and crop residues in some rural areas, and increasing prices for woody biomass in most urban centers” (Sokona, 2002).

The increasing use of dung and organic residues (crop residues, nitrogen fixing trees as *Acacia albida*) as fuel contributes to deteriorating soil fertility and declining agricultural productivity.

The loss of floodplains from dams and the attempted conversion of these areas to irrigated agriculture decreased and/or eliminated dry season forage areas for migratory pastoralists such as along the Senegal River, Volta River and Logone River. Dams across Africa have had a major adverse impact on traditional

⁵⁷ Other fuels include petroleum, gas, coal, electricity (hydro?)

pastoralism and other traditional sources of food production such as fishing and recession agriculture (see Chapter 7 on Dams).

In addition, “what cash crops have done for the Sahelian farmland, deep borehole wells have done for the pasture. A thousand feet or more beneath the Sahel lay vast reservoirs of water that can be tapped by deep wells. Well-intentioned donors have drilled thousands of these boreholes, costing up to US\$ 200,000 apiece, across the Sahel. The effect of the boreholes was simply to make pasture instead of water the limiting factor on cattle numbers, so that the inevitable population collapse, when it came, was all the more ferocious” (Hardin, 1977), (see Chapter 6 on Boreholes and Watering Points).

“Consequently, there has been a decline in the productivity of the livestock sector as well as a low output for the rain-fed cereal crops, estimated around 0.3 ton/ha in the Sahel zone, 0.5 ton/ha in the Sahel-Sudan zone, 0.7 ton/ha in the Sudan zone and 0.9 ton/ha in the Sudan-Guinean zone” (CORAF/WECARD, 2002).

However, de Haan, Steinfeld and Blackburn (1997) argue that

“livestock production in five Sahelian countries over a 30 year period, carried out as part of this study, shows a 93% increase in the meat produced/ha, and 47% increase in the meat produced/head. At the same time, there was a 22% increase in the animal population (from 14.5 to 17.6 million TLU⁵⁸) over the same period. This productivity increase occurs in both cattle and small ruminants. Part of the increased productivity may be the result of a progressive shift of the livestock population to the higher potential areas in more humid zones, and the increased use of crop residues” (see Chapter 6, Section 6.1.4.1 Impacts on pastoralism and range ecology from increases of human and livestock populations in the 20th century).

Groundnuts, Mourides and Land Degradation in Senegal

⁵⁸ Burkina Faso, Chad, Mali, Niger, Senegal and Sudan

Peanuts/groundnuts were introduced to Senegal by the French as a source of peanut oil for the mother country and were promoted by the newly independent government as a major source of foreign exchange (Figure 5.5). Boone (2003) explains that under colonialism beginning in the 1920s the French moved from power sharing with a decaying Wolof aristocracy to the charismatic Sufi *confréries* (brotherhoods) of Mourides and Tidjane who cleared forests, established farming communities and devoted themselves to prayer and the production of groundnuts. Old forms of political structuration under the Wolof Empire [see Chapter 1, Section 1.4.7, Wolof (Djolof) Empire] were transformed from the political to the religious realm as well defined *maraboutic* hierarchies of *grand kalifs*, the *grand kalifs'* eldest sons, and key lieutenants who made up a stratum of *grand marabouts* reaching all the way down to the village level chieftaincies, a quasi-feudal system encouraged by the French (Boone, 2003). “Traditionally, Muslim land tenure rules favor crop farmers over pastoral herders in access to land because ‘laying of the hand’ (e.g., evidence of use) confers exclusive ownership” (de Haan, *et al.*, 1997).

The *marabouts* of the Muslim sect of Mourides in Senegal can be considered an elite who control national, regional and local politics. They use their followers, the *talibés* (disciple or student) as tenant farmers who cultivate without pay (Dumont, 1966; Boone, 2003). In a process of land pioneering, unemployed warriors and freed slaves clear the bush, and cultivate the *marabout*'s fields for ten years after which they receive land of their own. In addition, each village collectively cultivates a field of which the harvest goes to the *marabout* with the income of lower level *marabouts* making its way through the hierarchy to the top (Boone, 2003). This has helped finance the “*Grand Mosqué*” of Touba (Dumont, 1966) though Boone (2003) states that France also helped fund its construction in the French government's alliance with the Moslem holy leaders as a means of controlling the economy. France used its alliance with the Mouride marabouts to

increase the powers of an alien colonial state and expand export-crop production. Groundnut cooperatives *Société Indigènes de Prévoyances* (SIPs) controlled by marabouts directly taxed Senegalese peasants and provided inputs and loans, while at the same time subsidizing “maraboutic estates” and eventually expropriating land from Peul/Fulani pastoralists in the Ferlo beginning in the 1930s. This included the cutting of roads and digging of boreholes by French colonizers to facilitate this expansion of *terres neuves* (new lands). Eventually, *forêts classés* (classified forests) were created to provide some grazing habitat for the Fulani pastoralists, though in the 21st century these forests are under assault as described below (Boone, 2003).

René Dumont (1966) argues that turning Senegal into a peanut and cotton cash crop economy resulted in the displacement of sorghum and millet food cereals. He goes on to say that as a result of this policy, there was a high incidence of young people suffering from protein deficiency or kwashiorkor, who were characterized by reddish hair and distended bellies. This illness resulted in them becoming physically and mentally scarred for the rest of their life, even if they recovered.

At the principal author’s arrival in Senegal in 1977, because of these relationships and the general over-population of the country resulting in reduced fallow periods, and inappropriately managed boreholes, Senegal as a whole was a degraded habitat, and was with the exception of the extreme southeast, devoid of wildlife other than crop pests consisting of warthogs, hare, dove/pigeon, quelea, francolin and a few guineafowl. It was heading towards desertification and the marginalization of its people. Some call Senegal’s Groundnut Basin “*désert arachide*”, the groundnut desert (Rosenblum & Williamson, 1990). Boone (2003) argues that Senegal’s 1964 *Loi sur le Domaine National* (National Domain Law) also discouraged fallow since the *Conseils Ruraux* (Rural Councils), consisting

of about 35-50 villages, five groundnut cooperatives and 10-25,000 people, were controlled by the *marabouts* and their followers and could confiscate any land that appeared to be under- or unutilized. Meanwhile, the 1964 *Program Agricole* (agricultural program) provided fertilizers, seeds and extension that were diverted mostly to the lands of village leaders and *marabouts*, while the peasants were never paid enough by the groundnut marketing boards to cover the costs of inputs and credits. By the end of the 1960s, peasants accepted credit, refused fertilizers, began prioritizing food crop production and sold groundnuts on illegal parallel markets.

According to René Dumont (1966), it was typical for land to be cultivated for peanuts with no fertilizer for three years, after which the earth was greatly depleted and the capacity to retain water diminished. The *marabout* would then force out neighboring farmers and cultivate their land until it was in ruins. The *marabouts* tended to invest their profits into urban businesses to the detriment of agriculture and industrial progress. In fact, Boone (2003) suggests that *marabouts* began shifting to commerce in the mid- to late 1970s as the groundnut (peanut) economy continued to decay into the 1980s and 1990s, at the same time employing members through a patronage system of import-export circuits that circumvented Senegal's trade laws. Speaking on the *Grand Mosqué* of Touba "an image comes to mind, that of a mosque built by ruining the surrounding earth, a mosque that will ultimately look over a man-made desert", and yet these very *marabouts* could serve as tools to transfer sustainable agricultural technology to their followers (Dumont, 1966).

The National Domain Law and the Rural Councils permitted *marabouts* to continue land pioneering into the 1990s, reallocating unused or under-utilized land that was critical to Peul/Fulani pastoralists (Boone, 2003). In 1991, the Senegalese government granted the Khalifa General (Supreme Head) of the

Mouride Islamic Brotherhood permission to plough more than 60% of the Mbégué forest reserve (located between the towns of Kaolack and Linguere) into peanut fields.

A year later (shortly before the national elections) the Mouride leader urged his followers to support Abdou Diouf in his bid for re-election as President of Senegal (Freudenberger, 1995).

“Following the orders of their leader, Serigne Mbacké, within a matter of weeks his followers cut down more than 5 million trees and brutally expelled more than 6,000 FulBe (Fulani/Peul) pastoralists and 100,000 cattle from the forest. Two months later, the rains began: the once-lush pastures were ploughed under and the land planted with a vast plantation of peanuts” (Freudenberger, 1995).

This forest lies just south of the Sahelian Ferlo in the heartland of central Senegal, where Fulani and their humped-backed Zebu cattle and farmers are colliding, as all across the Sahel. The Mbégué Forest, until it was destroyed, was a *forêt classé* established during the colonial era, where farming was prohibited, but grazing was allowed, serving as “insurance pastures” for Fulani and their livestock during dry years, with 38 watering points of which 35 are today surrounded by peanut fields. In the 1950s, boreholes were drilled 200-300 meters in the areas at 30 km intervals, resulting in the Fulani becoming sedentary around the boreholes, with some of the men moving the cattle during the dry season, depending on available pasture and/or temporary water (Freudenberger, 1995).

“In the first major Sahel drought (1972/73) following the FulBe settling around the boreholes, many families thought they could depend on the wells and not move south. They suffered tremendous loss of animals due to shortage of grass even when water was sufficient for drinking. In the next drought (1983) they revived their traditional strategies and moved south. They lost

fewer livestock and recovered more quickly from the disaster” (Freudenberger, 1995).

Chapter 6, Section 6.1, IMPACTS OF BOREHOLES ON PASTORALISM provides additional discussion on the impacts of boreholes on livestock and their habitat. Similar observations were made by a Fulbright scholar in Senegal in the mid-1980s about the elimination of classified forests further south, linked to charcoal production (see Section 5.9.4.7, Deforestation in savanna environments - Deforestation in Senegal linked to charcoal making, over-population and declining fallow periods).

Today, the Fulani of Senegal are being compressed from all sides, with the significant reduction in flooding from the Manantali Dam along the Senegal River, orchards and gardens to the west of the Ferlo along the coast for winter vegetables and fruit for Europe and Dakar. As lands further south are degraded and population pressures increase, farmers are tempted into areas previously considered too dry for agriculture. Each year new fields are cleared around the boreholes, blocking access routes used by cattle as they move from one pasture area to another and creating bitter conflicts between herders and farmers. Much of the new settlement in the region is organized by the same Mouride sect that took over the Mbegué forest lands. Bureaucrats in Senegal’s capital, Dakar, argue that concern for the Fulani’s nomadic lifestyle is a sentimental attachment to an archaic way of life, not understanding the role of nomadism in the management of these savanna ecosystems. Meanwhile, the growing of peanuts in these sandy soils is resulting in major soil degradation as the entire plant is uprooted at harvest, opening these peanut fields up to major soil erosion, especially aeolian from the Harmattan winds (Freudenberger, 1995).

“When the FulBe can no longer move their cattle in search of better pastures, they will be driven to a different kind of migration;

a path which will take them to the crowded slums of Dakar” (Freudenberger, 1995).

Before that, the process of desertification will likely occur.

5.6.1.2 Impacts of colonialism on traditional agriculture in the Zambezi Delta of Mozambique

In the 16th century, Portuguese settlers arrived, confiscating land and co-opting labor. Land was organized as *prazos*, parcels handed to individual white settlers, granting the owner powers over the local chiefs, taxes and the trade in slaves. Agricultural productivity was low, producing sesame, coconut, copra and groundnuts that were traded for gold, ivory and cattle. The *prazo* communities pushed for independence similar to the original chieftaincies (Isaacman, 1972 *In:* Beilfuss, Bento & Dutton, 2001). Eventually, however, the central government gained economic control of the *prazo* system through the development of port facilities and land concessions for plantation agriculture. By the end of the 1800s, Africans were denied individual property rights, which were given to foreign companies to develop plantation agriculture. The first commercial farm, the Mozambique Opium Cultivating and Trading Company at Mopeia, was established in 1870. The first sugar processing plant started production in Mopeia in 1893. In 1920, the Sena Sugar Estates were founded, and by 1930, the estates had acquired more than 100,000 ha of the most fertile agricultural lands of the Zambezi Delta, near Marromeu, Luabo and Mopeia. Cotton was introduced as a compulsory crop in 1926 and rice in 1941 (Beilfuss, *et al.*, 2001). The introduction of compulsory cotton growing by Africans made the estates fear a loss of labor (IFAD, 2002). To comply with the government’s cotton directive and avoid labor shortages, the estates gave cottonseeds only to women! At peak production, 346,000 ha of delta lands were in cultivation, with more than 293,000 ha (85%) of the total titled for the commercial production of cash crops and

livestock under the Sena Sugar Estates, Madal Society, and others (Beilfuss, *et al.*, 2001). Another threat to labor availability was the growing of maize by Africans, since they could sell it instead of working for the plantations. In 1936, the government explicitly excluded Africans from commercial maize growing, thus securing a protected market (and labor supply) for estates and settlers (IFAD, 2002). The allocation of land to commercial farms pushed small landowners onto marginal lands and later reduced the size of lands available to them. Landholding size per family in the delta eventually decreased from 15 ha in the 1930s to less than one ha during the 1970s (Negrão, 1995 *In:* Beilfuss, *et al.*, 2001). Tinley (1977 *In:* Beilfuss, *et al.*, 2001) attributes this increasing land use pressure among rural villagers for clearing the remaining riverine and forest vegetation in the Delta. Firewood (cordwood) demands for the sugar processing plants further contributed to local deforestation (Beilfuss, *et al.*, 2001).

5.6.1.3 Impacts of colonialism on traditional agriculture in Malawi (Nyasaland)

In Nyasaland (Malawi), large tracts of land were ceded to plantation owners (white settlers) forcing Africans to pay rent in the form of labor known as *thangata* (30 days labor). Peasant farmers were removed from good land, which was given to the plantation, to poorer lands. As a means of encouraging people to work on the plantations, people living on Crown Land (off the plantations) were forced to pay a hut tax of six shillings, the equivalent of 30 days labor, which was waived if they could show that they worked on the plantations. In 1906, peasant farmers cultivated cotton, thereby raising money to pay the hut tax. By 1912, the basic configuration of the present Malawi agricultural sector had emerged; this was an estate sector in the Shire Highlands producing cotton and tobacco, a cash-cropping peasantry using hoe cultivation to produce cotton, tobacco, groundnuts, maize and other crops and seeking employment when needed, and a large reserve

of migrant labor from the north and central districts of the country, where plots were too small to enable the peasants to meet the tax and financial obligations created by the colonial regime (IFAD, 2002).

5.6.1.4 Impacts of colonialism on traditional agriculture in Zambia (Northern Rhodesia)

In Northern Rhodesia (Zambia), 9 million ha (6% of the country) were set-aside for white farmers along the railway line in the 1920s. By 1940, only 800,000 ha had been taken up by 260 white farmers, clearing only 28,000 ha. This resulted from a failure to develop a viable export crop. Maize became the principle crop, of questionable viability, to feed the internal domestic market and mining industry of the Copper Belt. Fixed pricing and a single marketing channel, often denied black farmers, was the British system used to favor white settlers in commercial endeavors (IFAD, 2002).

5.6.1.5 Impacts of colonialism on traditional agriculture in Namibia

Only achieving independence in 1990, Namibia's land distribution system is a reflection of its colonial past. In 1994, 4,045 white farmers owned about 45% of the total land and 74% of the land suitable for farming. The remainder was used by 120,000 black families. Black communal areas contained 33 million ha, while white farms controlled almost 35 million ha. Whites represented at most 7% of the population; blacks at least 93% (IFAD, 2002).

5.6.1.6 Impacts of colonialism on traditional agriculture and dongas in Lesotho (British Basutoland)

To avoid cattle raiding and the slave trade by marauding Griqua, European and Khoisan horsemen and Zulu expansion, *mfecane*, the Basotho chief, Moshoeshoe, led his people onto the Thaba Bosiu Mesa in 1824. This was a defensive high ground with pasture in the Drakensberg Mountains, while below lay the region's best-watered lowlands where mainly women with hoes cultivated sorghum and maize. Through his military leadership with cattle as social capital, Chief Moshoeshoe forged the Basotho nation (McCann, 1999). Traditional land management is described in Chapter 2, Section 2.3.1, Land.

By the 1830s, the mark of the Voortrekkers (white Afrikaners of mixed Dutch, German and Huguenot descent) began to be felt as they sought out rangelands for their cattle. In 1838, after the Zulu chief Dingane had murdered the Afrikaner Piet Retief and his delegation seeking land, the Zulu were defeated at the Battle of Blood River. As these settlers arrived at the edge of Lesotho's territory, Moshoeshoe welcomed them. In 1846, the Afrikaners (Boers) founded the town of Bloemfontein, "fountain of flowers", close to Thaba Nchu controlled by Moshoeshoe (McCann, 1999).

Eventual struggles over borders were really struggles over the control of land and other natural resources (e.g., water). In 1843 and 1866, war broke out between the Boers and the Basotho as the Boers pushed into Lesotho territories and incidences of cattle theft increased. In order to protect itself, Lesotho requested help from and was annexed by Great Britain in 1868. By the time it was all over, the Basotho had lost one of their most fertile pieces of land, the Caledon Valley, which they had controlled since the 1830s (McCann, 1999).

By the mid-1850s, missionaries introduced the ox-drawn plow, as well as exotic crops and livestock that were to have a major impact on long-term soil conservation in Lesotho. The ox-drawn plow allowed for a dramatic increase in

agriculture to supply the Kimberley diamond mines discovered in 1867 and the gold mines of Witwatersrand (Johannesburg area) (McCann, 1999) beginning in 1886. By the 1890s Lesotho had entered into the international market to such a degree that the production of wheat, maize, Merino sheep and Angora goats exceeded its production of the food staples of sorghum, milk and cattle (McCann, 1999).

By 1873, 15,000 Basotho worked in diamond mines, the number increasing to 30,000 by 1886. By 1920, only 20% of the adult males were employed in agriculture. This placed agriculture, predominantly in the hands of women who shifted from labor-intensive wheat, which could be more cheaply imported from overseas, to low-labor maize. By 1930, Lesotho became a net importer of grain. By 1970, only 6% of the rural household income was derived from domestic crop production, the majority of the population living on remittances sent by men working in South Africa's mines (McCann, 1999).

Missionaries eliminated natural trees such as wild olive (*Olea africana*) in building schools and churches at mission stations and introduced exotic trees (poplar, *Eucalyptus*, Blue Spruce, Peach, etc.). Prior to plowing, the grass fields were burned, killing native trees and shrubs, while reducing indigenous vegetation to protected streambeds and mountainous ravines. By 1900, profound changes in the landscape were being observed in the disturbance of Lesotho's fragile piedmont soils due to the entry of Lesotho into southern Africa's modern political economy (McCann, 1999). :

- Imported sheep and goats over-grazed native grasses resulting in succession to less-palatable grasses;
- The cultivation of winter wheat associated with mission stations introducing plow agriculture;

- Maize replaced sorghum as the dominant national food crop; and
- Sledges and ox carts along cattle tracks reduced ground cover.

All of these activities, along with fire, exposed these fragile soils to torrential rain runoff resulting in gully erosion and the formation of “*dongas*”,⁵⁹ especially around mission stations. When *dongas* appeared, farms were no longer the primary source of livelihood. Soil conservation by colonial administrators, beginning in the 1930s, made matters worse and is a root cause of the *dongas* observed in the 1990s (McCann, 1999), as described below.

As in West Africa, the problem was not one of degraded conditions from traditional land use, but land compression, introduction of exotic cultigens, pushing local people into a moneyed economy, introduction of new technologies and little understanding of soil chemistry or physics by the colonial masters. In Lesotho, between 1935 and 1964, 207,872 ha had been terraced with 42,747 km of terraces, 2,555 km of diversion furrows and 2,254 km of meadow strips. These actions, undertaken as cheaply as possible and imposed on the local people against their will increased erosion by forcing water into channels creating subsoil “piping” which then collapsed and formed dongas that crisscross agricultural lowlands (McCann, 1999).

In comparison, on the white-owned lands of the Free State, when *dongas* appeared on newly opened South African soils, government paid half the cost for farmers to take mitigative measures, building dam walls on the *donga* face that served as livestock tanks, or the construction of retaining walls so they would fill-in quickly. The few *dongas* visible in the eastern Free State today are stable or reclaimed (McCann, 1999).

⁵⁹ Gullies

The situation has not improved in recent times.

“A UN team assessing agriculture in Lesotho in 2002 noted that agriculture faces a catastrophic future; crop production is declining and could cease altogether over large tracts of the country if steps are not taken to reverse soil erosion, degradation, and the decline in soil fertility. Nearly half of the children under five in Lesotho are stunted physically. Many are too weak to walk to school” (Brown, 2003a).

Turner (2004 *In: Fabricius, Kock, Magome & Turner, 2004*) explains that Lesotho, with a human population that has doubled since 1966, is 17% overstocked with livestock. The government has discouraged the movement of livestock to summer grazing grounds in the now highly populated highlands. The government and USAID funded attempts from the 1970-1990s at improved range management through the creation of Range Management Areas (RMAs) of 10,000 – 35,000 ha and community Grazing Associations (GA’s). They have had limited success, not exceeding 10% of the national rangelands. However, other factors are coming into play that will likely reduce livestock numbers including the following: 1) increase in stock theft and open access ranges. Many feel this is because of reduction in power of traditional authorities, the chiefs, while favoring weak village institutions created and supported by the government/donors, 2) livestock is only owned by the better-off rural households, while very poor households rely on wild resources to survive such as firewood, and wild vegetables from the grazing areas, 3) with free primary education, former herd-aged boys are going to school, which is resulting in a major labor constraint, and 4) a shift towards tourism has taken place as a way of generating wealth in these rural areas, though this latter change appears to be donor driven through UNDP/GEF’s Conserving Mountainous Biodiversity in Lesotho, and the Maloti-

Drakensberg Transfrontier Conservation Area (TFCA) Project. This has resulted in a smaller number of livestock being owned by a minority of the rural population, thereby significantly reducing grazing pressure. The Basotho people reject both “open access” and “privately owned fenced ranges” in favor of common property managed community-based range management systems (Turner, 2004 *In: Fabricius, et al.*, 2004).

5.6.1.7 Impacts of colonialism on traditional agriculture in South Africa

The Glen Grey Act of 1894 limited black farmers to 10 acres (4.2 ha) each. In 1910, one key goal of the South African government was to ensure adequate supplies of cheap labor to the mines. Despite previous efforts to restrict African farming to either reserves or manorial estates and to subsidize white farmers, black farmers continued to maintain a competitive edge in the market place. The chronic labor shortages on white farms were intensified by the emergence of the mining and manufacturing industries with their massive labor demands. The Natives Land Act, under British rule, was passed in 1913 (IFAD, 2002; Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*) and 1936 (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*), compressing the African population (80% of the total population) onto 13% of the country’s land in native reserves, which could not support them economically. Others estimate that 70% of the population was crowded onto 8.5% of some of the country’s worst land (Rosenblum & Williamson, 1990). Huntley, Siegfried and Sunter (1989) estimate that by the late 1980s, 42% of the population (14 million out of a population of 33 million) was on 13% of the land, implying that there has been a massive urban migration, as planned, to serve the mines and industry. The 1936 Natives Trust and Land Act and the Group Areas Act of 1950 continued to impact urban and land rights for non-white South Africans (Bernstein, 2005).

Most of the forced removal took place between 1958 and 1988, displacing 3.5 million blacks into unsuitable areas, a product of the alliance between “gold and maize” (Magome & Murombedzi, 2003 *In: Adams & Mulligan, 2003*).

Huntley *et al.* (1989) estimate that of South Africa’s territory of 122 million ha, just under 101 million ha were farmland (agriculture, livestock, game ranches) in 1989, of which 16.6 million ha (16.4% of the farmland) were arable. Bernstein (2005) provides the figure of 100 million ha of commercial land, meaning owned by whites. Of the arable land, 3% has high potential, while 10.5% has medium to low potential. About 65% of the land is non-arable with under 500 mm of rainfall/year and 21.5% is non-arable with rainfall above 500 mm/year. This non-arable land is suitable for livestock and game ranching (Huntley *et al.*, 1989). Bernstein (2005) states that 13.7% of the total land area as potentially arable.

The inequity in the distribution of arable land is similar to that of Zimbabwe. In 1989, about 50,000 white South Africans had 70% of the farmland at 85.4 million ha (1,700 ha/farmer) of which 14.3 million ha (286 ha/farmer) was arable. About 25% of these white commercial farmers accounted for 75% of South Africa’s agricultural output/production (Huntley, *et al.*, 1989). It is estimated that there are 91,000 black commercial farmers in South Africa but with much smaller land holdings (Bernstein, 2005).

In the crowded homelands 700,000 farmers had 13% of the farmland or 15.1 million ha (22 ha/farmer) of which only 2.3 million ha (3.3 ha/farmer) was arable. In addition, this was along with an inadequate distribution of industry to absorb this ever-growing population. These homelands produced 6% of South Africa’s agricultural output/production (Huntley, *et al.*, 1989). Similarly, Bernstein (2005)

provides the figure of 3 million ha of high quality agricultural land owned by black South Africans.

The overall percentages for land utilization in South Africa are 68% grazing, 14% arable, 10% nature conservation, 1% forestry and 7% other (Department of Agriculture, 2001 *In:* Bernstein, 2005). While white commercial farms provide 90% of the market produce, most farms are not part of this production. More and more, especially in the drier areas, they are opting for game ranching and ecotourism (Bernstein, 2005).

The figure of 0.16 ha of arable land/person (of the total homeland population) in 1989 was projected to decrease to 0.1 ha of arable land/person in the homelands by 2000 compared to 0.51 ha of arable land/person expected to drop to 0.36 of arable land/person in the whole of South Africa against a global norm of 0.4 ha of arable land/person (Huntley, *et al.*, 1989)⁶⁰. One does not have to look too far to understand why the homelands cannot feed themselves, meeting only 16% of their needs, and why much of the land is degraded since it should never have been farmed in the first place (Huntley, *et al.*, 1989). The National Department of Agriculture (2003) estimates that:

- 50,000 medium to large commercial farmers manage 61,000 commercial farms on 82 million ha;
- 240,000 small commercial farmers provide local and regional markets, principally to informal traders;
- 1 - 3 million rural householders produce food primarily to meet their family's needs; and
- 14.5 million ha of farmland was available in the former homeland areas.

⁶⁰ See Section 5.9.1, Over-population, Land Scarcity and Decreasing Agricultural Production in Sub-Saharan Africa, Table 5.16 shows 0.27 ha/person in Africa and 0.26 ha/person globally of crop land.

Impacts of Colonialism on Traditional Agriculture and Livestock in the Old Transvaal, South Africa

The Transvaal's post-Anglo-Boer War reconstruction was based on imperial ideas of progressive agriculture, estate management, and racial supremacy. Most important was the belief in the superiority of whites over Africans and from this followed the conviction that the Transvaal must become "white man's country". This is why in 1902, the British did not entrust the local administration to chieftaincies or encourage African peasants to produce cash crops and livestock for the local mine-dominated market. This would not have been acceptable in a settler economy, as it would have meant competition from Africans. In addition, it might have disrupted the flow of cheap labor to the mines. Veterinary resources, surveying, fences and beacons supported European land settlement schemes as the land was parceled and divided in creating a European landscape. A new beef frontier was established to supply cheap meat to urban mine-dominated markets. The settlement projects were also part of a broader policy of encouraging Africans to take up wage labor, the state taking great measures to marginalize rural African societies through land dispossession and restrictions on peasant production, including taking protectionist measures against a competing pre-colonial tradition of cattle husbandry and trade (Milton, 1997 *In:* Griffiths & Robin, 1997).

5.6.1.8 Impacts of colonialism on traditional agriculture in Uganda

In Tanzania and Uganda, the colonial regimes actively promoted production by African farmers, rather than large-scale farming by Europeans (IFAD, 2002), though it was not always the small-scale farmers who benefited.

As part of the “Ugandan Agreement” of 1900, the Ugandan colonial power, Britain, gave the Buganda and Bunyoro elites control of 25,900 km² (10,000 square miles) (12% of the protectorate) in one-mile-square *milos* (*mailo*). These elites enriched themselves by developing private estates on which they used peasant labor to produce crops exported by the British (IFAD, 2002).

Mair (1977) and Chrétien (2003) discuss this as mainly occurring in Buganda. Barrow, Gichohi and Infield. (2000) speak of this agreement affecting the Buganda, Toro and Ankole districts. The colonial power, not traditional rulers, developed a feudal-like system, in which the mass of peasants were reduced to tenant farmers (*bakopi*) who were stripped of their former lineage rights. In addition, private property became a monopoly of the oligarchy, a new class of African landlords who were rewarded for their collaboration with their colonial powers and associated missionaries (Mair, 1977; Chrétien, 2003).

“Though the land was supposed to have been granted on free, uncultivated land, this was often not the case and thus formerly ‘free’ peasant farmers were suddenly converted into tenant farmers required to pay rent to landlords (Doornbos, 1978 *In:* Barrow, *et al.*, 2000). This imposition of a foreign land tenure system onto a traditional one caused considerable social dislocation, the effects of which continue to be felt today” (Barrow, *et al.*, 2000).

According to Mair (1977) there were 1,000 chiefs – royal clients or their clients were given freehold private ownership of land; the majority holding no administrative position as “chief”. According to Chrétien (2003), the “thousand” was discovered to be 4,000 by 1921, including *bakungu* chiefs,⁶¹ *batongole* chiefs⁶² and a number of clan chiefs (*bataka*)⁶³. The control of land was

⁶¹ Traditional political and often military leaders at a sub-regional level with direct communication to the king or *Omugabe*, and minor chiefs in the Ankole (Nkole) Kingdom (Mwambutsya, 1991)

⁶² Bugandan chiefs today at sub-parish level – lowest level below in order of importance: 1) *Ssaza* (county) chiefs, 2) *Ggomboloa* (sub-county) chiefs, 3) *Miluka* (parish) chiefs and 4) *batongole* (sub-parish) chiefs (The Monitor, 2004).

independent of any political responsibility. In Busoga and Bunyoro, Uganda Protectorate officials realized that this system was unfair to the mass of the population who had to pay rent for land and were thus refused freehold grants. In Bunyoro, they issued “certificates of occupancy” to anyone guaranteeing continued occupancy as long as the land was cultivated. Demanding rent, however, was made illegal. However, both the Nyoro and Ganda believe that a chief is a man to whom others are attached. In essence, the same thing happened. Every man who obtained a civil service job as a “chief” obtained a grant of inhabited land and a certificate of occupancy from the ruler. This created “landlord-chiefs”. Busoga was left alone during the colonial period, with traditional village headmen allotting newcomers land, but now land cost, first paid for in kind with bark cloth and eventually with money that was given as a “gift” as was customary when someone approached a superior (Mair, 1977).

Attempts to resist the takeover of Buganda and Bunyoro by the British resulted in King Mwanga of Buganda, who had been put back into power by the British, and King Kabarega of Bunyoro being deported to the Seychelles in 1899 where they died in exile. Meanwhile, a “child king”, Daudi Chwa, and his “salaried” advisors were placed into power under the auspices of “indirect rule” where they served as proxies for the British colonial government (Chrétien, 2003). This marked the end of traditional land management systems in Uganda.

On the other hand, in Kigezi, southwestern Uganda, where there was a history of terracing, fallow agriculture, mixed cropping with nitrogen fixing legumes (peas and beans) (see Chapter 2), colonial attempts at soil conservation were integrated into these traditional systems. By the time changes were tried and modified, the colonial-introduced system was very close to the original indigenous system. Where there was success, it was because that which was introduced was similar to

⁶³ Bugandan elders (Mwanje, 2004)

the existing indigenous system. Education and propaganda, such as competitions for the best plots and yields was employed over force and traditional chiefs. In the 21st century, farmers continue to maintain fallow periods, but with a likelihood of increased differentiation in the ownership of land and livestock and increased landlessness, out-migration and residents living off remittances (Carswell, 1997 *In:* Adams & Infield, 1998; Carswell, 2003 *In:* Beinart & McGregor, 2003).

With considerable support from USAID and the World Bank, the new 1998 Ugandan land act assumes that (Barrow, *et al.*, 2000):

- “Customary tenure does not provide a basis for commoditization on the grounds that customary rights do not represent private, or tradable property; and
- Smallholding is a less desirable target for investment than commercial farming, and that opportunities to aggregate holdings must be available”.

This transforms landholding into “European” forms of ownership, weakening traditional rights, and in particular communal rights, supporting the interests of investors over the smallholder with minimal constraints upon land accumulation (Wily, 1997 *In:* Barrow, *et al.*, 2000). Meddling in traditional land use systems by both colonialism and Western donors has been the cause for much conflict around Lake Mburo, Uganda (see Chapter 11, Section 11.11.2, Donor Driven Conservation, Lake Mburo National Park (LMNP), Uganda). Much of the most potentially valuable areas for wildlife use are currently on communal land, such as in Karamoja. It is not clear whether the new legislation allows for communal land ownership (Barrow, *et al.*, 2000).

“Formerly communal land belonged to the state, and was under the control of the districts. The Local Government Statute also gives responsibility to district authorities for the management of natural resources. The implications of this are unclear. On the one hand it paves the way for more land to be expropriated, and on the other it enables districts to plan for the development of wildlife industries by controlling land use and working with Uganda Wildlife Authority (UWA) on the issuing of use rights” (Barrow, *et al.*, 2000).

5.6.1.9 Failure of colonial groundnut scheme in Tanzania (Tanganyika)

In 1946, “hundreds of miles of jungle were cleared by science and the bulldozer with a real promise of a better life for Africans and Europeans” (MacKenzie, 1997 *In: Griffiths & Robin, 1997*). The British Government, under the auspices of the United African Company, launched a program to transform 12,150 km² into groundnut cultivation for the production of margarine and oil destined for British consumers. No environmental (e.g., adequacy of rainfall, groundwater, socio-economic considerations) or soil assessment was undertaken. On most of the selected sites, though productive, the soils dried out and became too hard when exposed to the sun. In addition, there was massive gully erosion in the tracks left by tractors. Soils suitable for cropping were often limited in distribution and widely dispersed. Bush clearing was undertaken in blocks of 2.59 km², which was unsuitable for annual cropping. Since this failure, the production of groundnuts by large-scale mechanization has never been revived in East Africa (de Vos, 1975).

5.6.1.10 Impacts of colonization on soil fertility, Bukoba, Tanzania

This area, lying along the coastline on western Lake Victoria from Musira Island to Bukoba Bay, depended upon mixed animal husbandry and crop farming. The soil in the area was poor tending towards laterization, with pockets of fertile land

(20% of the land) coinciding with settled areas (Milne, 1938 *In: Kjekshus, 1977*). Rinderpest of the late 1890s had a major impact on soil fertility from a loss of manure. Grasses from the swamps and marshes were deposited over the agricultural plots to prevent laterization. Laterization transformed the soil mantle of grasslands uncovered for cultivation into oxides of iron and aluminum (Schmidt, 1974 *In: Kjekshus, 1977*) making them infertile. Not understanding the soil chemistry of the area, both German attempts in the late 1800s (Stuhlmann, 1894 *In: Kjekshus, 1977*) and British attempts in the 1930s (Schmidt, 1974 *In: Kjekshus, 1977*) failed at cultivating these grasslands.

5.6.2 Land Degradation Linked to Independence

The “English School” tends to blame post-independent Africa governments for much of Africa’s agricultural ills. Morris (1995) argues that many of the traditional systems survived colonialism and could have been developed, but that oppressive regimes emerging out of independence undermined indigenous institutions that enabled peasants and nomads to adapt to changing circumstances in much of Africa’s harsh and fluctuating savanna environments. Indigenous political systems were replaced by dictatorships and marketing systems by centralized government-marketing boards, which served as middlemen, underpaying the peasant producers and maximizing government profits on the international markets. The entrepreneurial middleman was eliminated, and thus the opportunity for the producer to negotiate prices according to supply (Morris, 1995). Morris (1995) does make some pertinent points concerning land degradation, admittedly implicating foreign aid in the actions of “African despots”, namely waste, corruption and the breakdown of indigenous institutions. This includes (to be discussed in more detail in later chapters):

- 1. Restrictions on the Private Ownership of Land and Natural Resources.** Land and natural resources on the land tend to be “owned” by the state, reducing the individual peasant's incentive and ability to invest in land and natural resources. This results in a “tragedy of the commons”, with land like wildlife habitat becoming an “Open Access Resource” and where reinvestment in soil conservation is less than if the land were managed by a single local communal authority. What Morris (1995) calls “political entrepreneurs” have caused land degradation by distorting the incentives faced by peasants and others. They often use the land for themselves or their political constituency and encourage overuse of land by generating uncertainty over property rights through forced migration, slaughter of cattle, denial of customary tenure, the under-pricing of agricultural output, and the subsidization inappropriate agricultural inputs (fertilizer, machinery, irrigation),⁶⁴ which can lead to wastage.
- 2. State-Subsidized Boreholes.** Peasants and nomads flock to these boreholes to take advantage of the “free” (un-owned and un-priced) water and land, becoming sedentary and degrading the environment (see Chapter 6). Examples include Botswana and across the Sahel.
- 3. State-Subsidized Dams.** Encouraged and financed by “aid” agencies, especially the World Bank, dams have destroyed traditional ecological production systems and millions of lives, especially those linked to downstream floodplains (see Chapter 7, Table 7.16: Major dams in Africa that have affected local communities). Examples include the Cahora Bassa and Kariba Dams on the Zambezi River and the Manantali and Diama Dams on the Senegal River.
- 4. State Subsidies to Irrigation and Mechanized Farming.** Linked to dams, inefficient state parastatal irrigation schemes have often been disastrous to the local ecology, traditional production systems and rural

⁶⁴ The authors would argue that some subsidies to farmers, as in the USA and EU might be appropriate.

residents (see Chapter 7). Examples include SAED (*Société d'Aménagement et d'Exploitation des Terres du Delta du Fleuve Sénégal*) and the Niger Office in the Inner Delta of Niger.

5. **Compulsory Resettlement Programs** from land to be flooded by state-subsidized dams, or simply at the whim of a dictator, have resulted in the disruption of social structures and traditional land/resource tenure. The new lands are often less productive (see Chapter 7, Table 7.16 - Major dams in Africa that have affected local communities).
6. **Compulsory Limits on Livestock Ownership** without looking at customary law, the role of cattle as a drought food, and the ability of cattle to eat a more diverse array of grasses than humans (e.g., humans can eat *fonio*, *Digitaria exilis*) have also had negative effects.
7. **The Knowledge Problem.** A more general problem with state intervention is its intrinsic inability to meet the needs of the people. Only an individual knows his/her own needs and wants and these are best satisfied through mutually advantageous exchanges in the market. People's needs and wants are no longer met as effectively. Intervention failure leads to a vicious circle of land degradation, aid, and oppression.

Morris (1995) and Chabal and Daloz (1999) place much of the blame on foreign aid bureaucrats and governments who spread the myth that local people do not understand the environment in which they live, and that they intentionally misuse the soils, let their livestock over-graze and have too many children. They also argue, that self-seeking autocrats undermine traditional management systems and control in favor of obtaining aid money to help overcome “starvation and desertification”, while actually misusing the money for their own purposes (see Chapter 11, Foreign Aid).

The following exemplifies the collusion between political elites of African governments and foreign aid bureaucrats. When the principal author arrived in Senegal in 1982, his counterpart,⁶⁵ now an environmentalist with the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD) drove him around the town and asked, “What is most striking to you”? The most striking observation in Dakar, the capital, was the large proportion of Mercedes Benzes given the level of poverty in the country. It was explained to the principal author by his counterpart, that the majority were purchased with misappropriated Western donor money, and in fact, there were ministers who stated openly that the last thing they wanted was for Senegal to develop, as this would mean less income for them, since their government salaries were too small to support their lifestyles. In the midst of the Cold War, donors buried their heads in the sand, with little or no attempt at recovering stolen “development” funds. The elites from both groups were not about to criticize a system that gave them privileged lifestyles and nice incomes.

However, this “English School” (Bull, 1977; Bull & Watson, 1984 both *In:* Dixon, 2002) neglects the role that the international capitalist economy has played in marginalizing Africa from the global mode of production, and has tended to overlook the extent to which it has served to induce frailty and instability in virtually all African states (Inayatullah & Blaney, 1995 *In:* Dixon, 2002) (see Chapter 13 on the International Private Sector in Africa). By locating the responsibility of African frailty with a few despotic rulers or fanatical groups, an accusation that is admittedly significant, the English School literature effectively exonerates International Finance Institutions (IFIs)⁶⁶ (– see Chapter 12 on Structural Adjustment), the structures of the global capitalist economy and the legacy of colonial rule from the continued economic paralysis afflicting African

⁶⁵ Idrissa Samba, I.SAMBA@AFDB.ORG and idisamba@yahoo.com

⁶⁶ IFIs include the World Bank, African Development Bank/*Banque Africaine de Developpement* (ADB/BAD), Inter-American Development Bank, Asian Development Bank and the European Bank for Reconstruction and Development.

states (Dixon, 2002). Benneh, Morgan and Uitto (1996) explain that the collusion between the African political elite (often well-placed politicians) and businessmen or agents (e.g., oil, timber, mining and agro-industries) of the former colonial powers is often overlooked to the benefit of both parties but to the detriment of the common people of Africa. This is discussed in greater detail in later chapters. Additionally, many of the policies, such as state ownership of land and natural resources, have been inherited from those established during colonial times and thus cannot be blamed entirely on African governments.

5.6.2.1 Marketing boards and cocoa, 2004 in the Ivory Coast

This process continues in the 21st century. In mid-2004, Ivory Coast cocoa unions were threatening to shut down the main city, Abidjan, if their demands for compensation money and reform were not met. Trade liberalization has been less than successful.

“About 6 million people rely directly or indirectly on cocoa revenues in Ivory Coast, which accounts for about 40% of world cocoa exports...Ivory Coast remains the world's leading cocoa producer, but civil war, falling prices and the semi-privatization of the sector have cut down earnings for growers of the fragrant bean...Liberalization of the sector since President Laurent Gbagbo took power in disputed elections in 2000 has been what he calls ‘savage’. Semi-private agencies, with financial independence but politically appointed leaders, have replaced state agencies to regulate the sector. A system whereby growers were ensured a minimum yearly price for their cocoa from buyers and exporters has been abandoned...Instead, planters have been paying a fluctuating charge on each kilogram of cocoa sold to a cooperative-type body called the Regulation Fund for Coffee and Cocoa. It has been about two cents this year, but more in previous years when cocoa prices were higher” (Colombant, 2004a).

Instead of compensating farmers when prices on the ground fall this body has been investing in projects that unions never approved. Some say the planters are

being robbed and are collectively owed about US\$ 80 million. In 2004, growers were getting as little as US\$ 0.40/kg of cocoa sold to buyers and exporters, compared to more than US\$ 1/kg the year before. The union was also threatening to start a third port in the Ivory Coast, apart from Abidjan and San Pedro, so they could control the lucrative sector themselves (Colombant, 2004a). Similar impacts from privatization of the marketing board for cocoa in Cameroon are discussed in Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People And The *Dobi Dobi*, More Parks And Protected Areas.

5.6.3 Foreign Aid and Impacts on Agricultural Production and Land Degradation

Foreign aid has had a devastating impact on agricultural production in Africa from promoting agriculture on marginal lands that may have more appropriate land uses, to dumping subsidized food from the West that is a disincentive to production by local farmers. This is discussed in greater detail in Chapters 11 and 12.

5.6.3.1 Agricultural bias by donors as solution a to Africa's backwardness – constraint to appropriate land use

Until the late 1980s, Western donors, mainly driven by agricultural economists, held that Africa's backwardness could be overcome by agricultural initiatives: improved crop production, tree farming, livestock and fish culture, and on-farm systems known as "integrated rural development", a policy that has failed (Eicher, 1990 *In: Eicher & Staatz, 1990*). There was little attempt to manage natural systems or to recognize that the majority of the poorest of the poor lived in marginal, over-populated and already degraded agricultural areas, some of which might have other preferred land uses such as tourism. This began to change in the

1990s with more attempts at managing natural systems and recognizing their potential for income generation as part of “food security” initiatives where one could buy food as opposed to “food self-sufficiency” policies of the 1970s/80s which held that each African and each African country should be able to produce all of its own food. Eicher (1990 *In: Eicher & Staatz, 1990*) was concerned that in a “blind determination to help Africa”, especially after the 1984/85 famine, there was a danger that donors would not critically examine the food and livestock failures in the Sahel over the previous 15 years of US\$ 15 billion in donor assistance and incorporate lessons learned into the design of natural resources projects in the 1990s.

5.6.3.2 Foreign assistance in Sahel goes for large scale as opposed to improving traditional agriculture

The Sahel provides a good case study of just what is wrong with much Western aid. The Sahel Development Program is a massive scheme supported by billions of dollars from the UN Food and Agricultural Organization (FAO), France, Holland, Belgium and the U.S. to “rid the Sahel of food shortages and ecological deterioration, to overcome dependency and to raise the incomes and quality of life for 26 million people”. The project has created a series of large-scale food production schemes over eight countries producing everything from rice (for urban areas) to beef cattle (for export). Only 16% of the billions of dollars of aid went to rainfed crops that poor peasants and nomads of the Sahel depend upon to survive. Most of the farming schemes involved large - scale irrigation and mechanized agriculture that excluded peasants (but benefited political elites and their constituency). Little attention was paid to increasing badly needed storage facilities or to ensuring a fair distribution of the new food grown (Elwood, 1984). Many of these large scale irrigation schemes have failed, while wiping out traditional production systems and making rural people poorer and worse off

nutritionally, while to some degree benefiting political elites of the host countries, aid bureaucrats, construction companies and consulting firms (see Chapter 7, Section 7.9.3.1, Senegal River and Section 7.9.5.1, Senegal River).

Irrigation along the Senegal River

At a cost of \$25,000-40,000/ha, instead of 375,000 ha in pumped irrigation, only about 100,000 ha have been brought under irrigation with only about 2,000 ha/year being added (Bosshard, 1999). With the average production of rice not exceeding three tons/ha/year (instead of the projected 12 tons/ha/year), pumped irrigation is economically questionable. As the Senegal River Delta was a marine bay that gradually filled in with sediment over the last few thousand years (Monteillet, 1988 *In:* Hamerlynck, Duvail & Ould Baba, 2000), there is an underlying hypersaline groundwater sheet at about 1 meter below average sea level (ASL) stretching to over 200 km inland. Current irrigation practices, usually without drainage systems, seem unsustainable because of increased soil salinity and large tracts have already become permanently unsuitable for agriculture (Hamerlynck, *et al.*, 2000). With irrigation, the traditional sorghum crop was replaced by rice. These problems were foreseen by the agronomist on the environmental assessment team, and were not hidden; projections were made, however, that irrigated crops would replace those lost from traditional systems. It is estimated that the lives of between 500,000 – 800,000 people were forever changed in a negative way from the loss of traditional food production systems (estuarine and freshwater fishing, recession agriculture, and dry season forage) on the floodplains and estuary for a technically, ecologically and economically unviable program (see Chapter 7, Section 7.9.5.1, Senegal River, Section 7.9.6.1, Senegal River and Chapter 12, Section 12.4.4.1, Impacts of structural adjustment on peasant farmers along the Senegal River for detailed discussions on development impacts on traditional agro-pastoral systems in the Senegal River

Basin). It was cheaper to import rice from Asia. Meanwhile, rice was subsidized in an attempt to make it artificially competitive. Rice is produced at a relatively high cost in irrigated areas of the Senegal River Valley and Upper Casamance, while producer prices were subsidized through 1994 (Kelly, Diagana, Reardon, Gaye & Crawford, 1996; Reardon, Barrett, Kelly & Savadogo, 1999), but at what expense in the long-term to the Senegal River Valley being able to feed itself based upon over 1,000 years of traditional floodplain irrigation (see CHAPTER 7: IMPACTS OF DAMS ON CONSERVATION AND DEVELOPMENT IN AFRICA)?

The Casamance, Senegal Traditional Rice Culture, Versus Modern Interventions

The Casamance is dominated by a mangrove estuary, with hypersaline waters at times exceeding 170 ppt - parts per thousand (Sea water is 35 ppt). It is situated in southern Senegal and sandwiched between the Gambia and Guinea-Bissau. It is dominated by the Jola (Diola) tribe that has practiced swamp rice culture in a harsh environment for centuries growing African rice (*Oryza glaberrima*). Swamp rice culture takes place in advanced mangrove soils by diking off a section of the land to be cultivated. The soil is allowed to be covered daily by tidal action. As the rains come, the area is gradually closed off from tidal inundation, and drained at low tide until the salinity of the soil and water is low enough to allow rice to grow. The soils are never allowed to dry out.

Dutch aid workers seeing this “primitive system of rice culture” were determined to improve upon the traditional Jola (Diola) practices by permanently diking off a large area of mangrove soils, which dried them out. These pyretic soils when dried out oxidized to form sulfuric acid. This resulted in acidic soils, low pHs and

heavy metal toxicity, turning productive soils, into sterile soils, where until today nothing will grow. For further discussion on the impacts of foreign aid interventions in the Casamance see Chapter 11, Section 11.7.9.2, Barrage De Affiniam, Casamance, Senegal; foreign aid big money, ecological destruction.

Cold War Politics and Western Donor Impacts on Food Production, Senegal

The principal author lived and worked in Senegal on and off from 1976 to 1988. As the furthest point west in West Africa, Senegal was strategically very important for the West during the Cold War. This included serving as a potential staging ground for interventions on the subcontinent (Senegal being renowned for its soldiers), serving as an emergency landing for the U.S. Space Shuttle, and serving as a no-go zone for Russians, who were only allowed to periodically send in an Aeroflot plane to change fishermen, as allied submarines are said to have plied deep canyons off the West Coast of Africa.

During the Cold War, the U.S. and France allegedly dumped money directly into the government coffers to pay the salaries of functionaries and maintain an artificial economy (see Chapter 11, Section 11.6.7, Foreign Aid and Puppet Governments – Donor Democracy). It is reputed that France paid approximately three times the World Market price for peanut oil. According to Badiane (2001):

“the Lomé Convention, originally established at the 1963 Yaoundé Convention between 6 European countries (Belgium, France, Federal Republic of Germany, Italy and the Netherlands) and their 18 former colonies of the Association of African States and Madagascar, enforced preferential trade agreements, notably access for raw materials to Europe, as well as financial and technical assistance to be financed by the European Development Fund (EDF). It allows duty free access to agricultural and industrial exports from selected developing economies”.

As a result, “France was committed, at least up to 1967, to buying Senegalese peanut exports at premium levels over prevailing world prices” (Boyle, 2000). Price support for peanuts to Senegal under the Lomé Convention ended by 1968 with France’s entry into the European Economic Community (EEC), now known as the European Union (EU) (Badiane, 2001) in fulfillment of the Treaty of Rome (Boyle, 2000). The EU took over from the French. To some extent, the EEC’s newly established European Development Fund (EDF) helped offset the loss of French subsidies (Boyle, 2000) . In turn, this “foreign aid” permitted government support to peanut farmers to continue. The impacts on peanut production and soil quality, when virtually all support, direct and indirect, to peanut farmers ended as a result of structural adjustment in the early 1980s, and the impact this had on soil quality is discussed in Chapter 12, Section 12.4.3.2, Impacts of structural adjustment on fertilizer use and intensification in Senegal’s Groundnut Basin. To some degree, the EU continues support to peanut farming. In the 21st century, as a result of the “Lomé Convention and preferential trade agreements between the European Union and the African, Caribbean and Pacific (ACP) Group of 44 countries, Non-ACP exporters of groundnuts face tariffs of 5 to 15% when entering the EEC market, thus giving a slight edge to Senegalese groundnuts” (Badiane, 2001). Small-scale farmers produced peanuts in Senegal, a policy that had continued since colonial times (see Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel).

Back in the 1970s and 1980s, peanut oil sent to France is reputed to have been refined a second time to remove carcinogenic aflatoxins that accumulated during storage from factors such as excess moisture and temperature (e.g., when temperature is within the range of 25-32°C and relative humidity is greater than 84%) (Soufi, 2001), while the harvested peanuts awaited transport to the refineries (see Figure 5.5: Mountains of peanuts in Senegal’s Groundnut Basin).

The French began a campaign to eliminate aflatoxin in peanut oil in the late 1980s (Bernier, 2005).

Prior to the HIV/AIDS pandemic, hepatic carcinoma (liver cancer), resulting from aflatoxin consumption of improperly stored grains and grain products (including peanuts and maize), was probably second only to malaria as a significant public health hazard in Sub-Saharan Africa (Peterson, *pers. comm.*). According to Miller (1996 *In:* Bankole & Adebanjo, 2003), 40% of the productivity lost to diseases in developing countries, including Sub-Saharan African, is due to diseases exacerbated by aflatoxins, with aflatoxin contaminated diets being linked to liver cancer. Aflatoxins are some of the strongest natural carcinogens produced by a mold (*Aspergillus spp.*) and are classified as “Class 1” human carcinogens (IARC, 1993 *In:* Bankole & Adebanjo, 2003). Recent EU policy changes on aflatoxin in 1997 (Badiane, 2001) could result in the reduction by 64% in imports of cereals, dried fruits, and nuts from nine African countries: Chad, Egypt, the Gambia, Mali, Nigeria, Senegal, South Africa, Sudan and Zimbabwe, resulting in an annual loss of from US\$ 670 million (Bankole & Adebanjo, 2003) to US\$ 400 million for African producers (Badiane, 2001). In a study carried out in the Gambia, Guinea-Conakry, Nigeria and Senegal, over 98% of subjects tested positive to aflatoxin markers (Wild, 1996 *In:* Bankole & Adebanjo, 2003).

Peanut oil extracted from poor-graded peanut seeds always contains very high levels of aflatoxins (Suttajit, 2005) and the oil-soluble toxin has to be eliminated by absorption (Ozdemir & Ozilgin, 1995; Suttajit, 2005) and alkalinization (Duke, 1983; Suttajit, 2005) during the oil refining process. Today, commercial peanut oil refineries in Senegal, whose oil is destined largely to an overseas market, use various techniques to eliminate aflatoxins (Badiane, 2001). However, Ndiaye, Diop, Diouf, Fall, Thiaw, Thiam, Barry, Ciss and Ba (1999) found high levels of

aflatoxins in small-scale pressed peanut oil, which would likely be used mostly for local consumption.

Additionally, people living in Senegal were forced to pay about 2.5 times the world market price for uneconomical irrigated sugar cane from a French-owned plantation, *Compagnie Sucriere Senegalaise* (CSS), in Richard Toll on the Senegal River Delta. Established in 1970, CSS

“was given 7,300 ha of land by the Government under highly favorable conditions, including 30,000 m³ of water/ha free of charge each year and monopoly of the market for sugar in Senegal. In spite of these advantages, CSS has already cost the Government vast sums, estimated at 14,600 million CFA⁶⁷ Francs (US\$ 584 million) in 1992, and the cost of a kilo of sugar in Senegal is much higher than the international market price” (Adams, 2000).

Maize introduced for livestock fodder by American agronomists in Senegal and the Gambia saw local people change their dietary habits, preferring corn to more-nutritious millet and sorghum (Table 5.10).

Table 5.10: Nutritional value of traditional grains and corn

Grain Crop	Grams Protein per 100 gram portion	Grams Carbohydrate per 100 gram portion
Maize Meal/Grits/Pap	8.80	79.60
Sorghum, <i>Sorghum bicolor</i>	11.30	74.63
Raw Millet, <i>Panicum miliaceum L.</i>	11.02	72.85

⁶⁷ Communauté Financière Africaine franc, originally at a fixed rate against the French Franc, since January 1, 1999 fixed against the Euro

Sorghum and millet are also much more drought tolerant than corn, while protein deficiency is currently a major problem in rural Senegal/West Africa. By the time the principal author left West Africa in 1989, fallow periods were greatly reduced or disappearing due to the ever-increasing human population.

5.6.3.3 Donor subsidized food as a constraint to agricultural production

Dumping of cheap subsidized food by the West in the name of food aid is also a disincentive to Africa feeding itself, often undercutting local food production. This also decreases the multiplier effect of money circulating within a country and stymies the development of agro-industries to transform locally produced products (Smith, 2001). Agricultural subsidies, giving Western farmers an artificial comparative advantage over unsubsidized developing world farmers, have been a major reason for the collapse of the September 2003 World Trade Organization (WTO) Summit. This is discussed in more detail in later Chapter 11, Section 11.8, FOOD AID and in Chapter 12 on structural adjustment and subsidies.

5.6.4 Structural Adjustment, Fertilizer Use, Food Production and Land Degradation in Sub-Saharan Africa

See Chapter 12, Section 12.4, STRUCTURAL ADJUSTMENT FOOD PRODUCTION AND LAND DEGRADATION IN SUB-SAHARAN AFRICA.

5.7 POLICY REFORM CONSTRAINTS TO AGRICULTURAL PRODUCTION

Although agriculture is increasingly recognized as the engine of economic growth in Sub-Saharan Africa, the level of government commitment to it is low.

Governments often penalize agriculture through a variety of mechanisms, including export and import taxes, foreign exchange controls, export licensing requirements and controls, and bureaucratic marketing boards. Food subsidies (i.e., food retail prices kept artificially low) have allowed governments to keep food prices low to appease urban constituents, but at the expense of rural producers. Such policies and practices have reduced farmers' incentives to increase local food grain production and to use modern inputs to improve productivity (Gruhn, *et al.*, 2000; Mule, 2003). Meanwhile, in the industrial countries agriculture enjoys an annual subsidy of \$US 300 billion - equivalent to Africa's total GDP (Mule, 2003) (see Chapter 12, Section 12.2, SUBSIDIES AND FREE-TRADE).

5.7.1 Property Rights and Land Tenure, Constraints to Soil Fertility and Agricultural Production

Insecure and crumbling tenure arrangements also contribute to declining soil fertility and thus agricultural production (see Section 5.5.2.2, Nutrient depletion as a constraint to agricultural production). The issuance of title deeds on its own may not be adequate if not complemented by other factors, such as improved infrastructure in rural areas – roads, education, health, markets, energy, etc. (UNECA, 2003). It is essential that they be accompanied by comprehensive programs of agrarian reform, including access to credit, savings and markets in rural areas if they are to fundamentally redress the inefficiencies of inequality (Roman, 2003). Mule (2003) argues that

“in Africa, the vast majority of farmers still hold their land under indigenous, customary land tenure systems. Several studies have shown that there is no marked difference in agricultural productivity between customary and individual land tenure systems. Community level institutions can therefore be used as important vehicles for agricultural development and poverty eradication”.

Likewise,

“in view of the precarious environment, farmers and pastoralists alike are served better by flexible land-tenure regimes that permit moving in order to make optimal use of available resources and production conditions. Livelihood security is attained through kinship relations that confer access rights in geographically dispersed pools of territories. In an unpredictable and precarious environment, geographic mobility is essential for actors to secure their livelihoods, both in the long and the short-term. Actors’ movements, as they appear from their land-use paths, not only are made possible by the prevailing land tenure regimes but also continuously promote its flexibility and the merging and shifting of rights to land. This argues against the establishment of western-type tenure security and in favor of the maintenance of flexible resource tenure regimes” (Breusers, 2001 *In: Lycklama à Nijeholt, de Bie & Geerling, 2001*).

Titling can result in mass sell-offs increasing land in the hands of a few elite and increasing landlessness among the rural poor (Madeley, 2002) (see Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya).

When a Westerner thinks of land tenure, he/she thinks of land owned by an individual. In Africa, land has traditionally been managed on a communal basis (Chapter 2). Very often in Africa today, governments have taken over where colonial regimes left off, and own all the land and resource rights. There is a tendency through decentralization/devolution processes to return land and associated resources back to these communal systems to assure its sustainable management, though this process is far from complete (see CHAPTER 9: COMMUNITY-BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS - THE WAY FORWARD?).

It is strongly urged that a close look be taken at “common property” management of land and its resources for soils, grazing, wildlife conservation, forest conservation and fishery conservation, since central governments have neither the means nor the manpower to manage and control access to these resources. The open access resource systems which governments inherited from the colonial powers are believed to be at the root of resource degradation on the continent (see Chapter 3, Section 3.4.1, Centralized Control of Natural Resources and the Arrival of Conservation), along with traditional extensive management of resources (e.g., long fallow periods, pastoralists moving from wet to dry grazing areas) becoming impractical and/or diminished as human and livestock population increased in the 20th century (see Section 5.9.3, Fallow Agriculture, Over-Population and Agricultural Production, Chapter 6, Section 6.1.4, Impacts of Colonialism and Post-Colonialism on Pastoralism and African Ecology and Section 6.1.4.7, Impacts on pastoralism and range ecology from increases of human and livestock populations in the 20th century). Sedentarization policies have added to this problem (see Chapter 6, Section 6.1.4.6, Impacts on pastoralism and range ecology from sedentarization policies and privatization policies). There is a crying need for entry into intensive management systems due to the tremendous increase in human and livestock populations, and changes in land tenure [e.g., group ranches in Kenya (see Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya), private ownership of clearly defined plots of land to subsistence farmers in South Africa] that often concentrate humans and livestock into systems requiring intensive management to sustain the populations, while minimizing habitat degradation.

Regardless of whether customary “communal” or freehold land tenure rights are pursued, this will require careful planning and policy analyses, such as defining the land use permissible in a given area, and a minimum size farm/ranch for that

land use beyond which subdivision will not be allowed, in order to prevent both economic and ecological non-viability. Participatory land use planning with rural communities will be required if improved land tenure systems are to be successful. There will be increased pressure for freehold land, which can be used as collateral for financing development of the property. It is strongly recommended that financing and lending institutions devise ways where communally owned and managed properties can also qualify for loans.

5.7.1.1 Niger, land tenure and soil fertility

In Niger, for example, secure land for growing millet accounts for 90% of the manured fields. These fields received an average of 307 kilograms of manure/ha/year, while unsecured millet fields received only 186 kilograms/ha/year (Hopkins, Berry, & Gruhn, 1995 *In:* Gruhn, *et al.*, 2000). Secure tenure does not necessarily imply individual titling, but could imply communally owned and managed land tenure as opposed to state owned or private land tenure.

Williams, Hiernaux and Salvador Fernández-Rivera (2000 *In:* McCarthy, Swallow, Kirk & Hazell, 2000) describe relations between pastoralists and farmers in southwestern Niger in the *Sahelo-Sudanian* (Sudano-Sahelian) zone where rainfall is between 400-600 mm/year (see Chapter 1, Figure 1.3. The Sahel) and the sandy soils are deficient in phosphorus and nitrogen. This area has historically been populated by the Djerma ethnic group, primarily farmers along with livestock-rearing Fulani who have settled in the area about a century ago.

"In the past, farmers obtained manure by arranging contracts with transhumant herders. These arrangements involve farmers' granting grazing rights to crop residues to herders in exchange for the manure deposited by the animals owned by the latter. The farming systems have, however, evolved over the years as a result of population growth and declining rainfall, which have exerted pressure on arable land...The principal cereal crop is pearl millet, which is grown either in sole stands or intercropped with cowpea. Where the land quality permits, sorghum and maize are also grown...Historically in the Djerma culture, land clearing establishes definitive property rights for the farmer regardless of the subsequent use to which the land is put (Breitschuh, 1990 *In: Williams, et al.*, 2000 *In: McCarthy, et al.*, 2000). Such land can be inherited, lent, rented, pledged, or left fallow without fear of being reclaimed. This system comes closest to private ownership, since the owner has full use, modification, and transfer rights, including the legitimate, but highly discouraged, right to sell land (Gavian 1993 *In: Williams, et al.*, 2000 *In: McCarthy, et al.*, 2000). The role of the village chief is to settle disputes and allocate land, held in common or from his own stock, to newcomers. In the Fulani system, ownership of all arable land is vested in the community, under the trusteeship of the village chief. The chief sets long-term use-rights for household heads. Each family head has full rights of modification and inheritance, but does not have the right to lend, rent, or sell the land. Land left in long-term fallow reverts to the community to be allocated to another user. In both systems, fallow or unallocated fields are open to animal grazing, as are cultivated fields after harvest...Farmers in this region have traditionally relied on long fallow periods for regenerating soil fertility. Fallow practices have, however, changed in response to increased pressure on arable land...fallow periods last for 2 to 3 years on borrowed land and 3 to 5 years on owned land—instead of the previous practice of 10 years or more...extension and credit is weak in the Sahelo-Sudanian region. Rural infrastructure is also limited, making the supply of inputs and marketing of farm produce difficult. As a result, farmers make minimal use of purchased inputs, such as fertilizers and feed supplements...Declining soil fertility arising from reduction of fallow periods and farmers' lack of access to mineral fertilizers have created a heavy reliance on animal manure for soil fertility maintenance...Average millet yields in the three villages in 1996 were 713 kg/ha on manured fields, compared with 396 kg/ha on un-manured fields. Manure is obtained from farmers' own animals and through contractual arrangements with transhumant herders.

Unlike in the past when contracts between farmers and herders were based on the exchange of crop residues owned by farmers for manure deposited by the pastoralists' herds, manure is now mostly exchanged for millet grain and cash. This trend has curtailed the ability of poor farmers to enter into manuring contracts with pastoralists and increased their reliance on manure from their own herds" (Williams, *et al.*, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

5.7.1.2 Ghana, land tenure and soil fertility

The lack of reinvestment incentives of sharecroppers in soil conservation/fertility appears to share similar characteristics with government ownership of land. In Ghana, for example, sharecroppers have put enormous pressure on soil fertility to realize immediate high yields in order to pay land rents (Benneh, 1997 *In:* Gruhn, *et al.*, 2000). Farmers in such situations discount the future at very high rates, thereby reducing the incentive for long-term investments in improved soil fertility.

5.7.1.3 Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya

Of Kenya's 587,900 km², only 17.2% is of high and medium potential supporting 80% of the population while the remaining over 80% is arid and semi-arid supporting 20% of the population. The 17.2% land category contains important natural/indigenous forests that serve as water catchments that are under tremendous pressure (Lumumba, 2005 *In:* ACTS, 2005).

The two arid/semi-arid districts of Kajiado and Narok that encompass modern Maasailand cover approximately 36,000 km² of land. Average annual rainfall

varies from 300 to 800 mm in Kajiado and from 500 to 1,000 mm in Narok. In 1979, the average population density was seven persons/km² in Kajiado and 13 persons/km² in Narok (Jaetzold & Schmidt, 1983 *In: Swallow & Kamara In: McCarthy, et al., 2000*).

One of the worst governmental and Western donor (e.g., World Bank) policies ever introduced was the creation of group ranches in Kenya, without regard for ecological complimentarity (a ranch needing wet and dry season habitat for extensive management). Group ranches provided for community ownership of the land, but not the most valuable resource on the land – wildlife – and the right to use wildlife sustainably as an economical resource. Nyika (2007) calls this a tragedy in which “owners of the land also become ‘owners’ of the costs of wildlife, without gaining the benefits, which are ‘owned’ by the state”, the state “indulging in predatory rent seeking, by owning the resource which depends on the land owned by someone else”. There was also a lack of land use planning and zoning (e.g., maintenance of wildlife/livestock habitat). Group ranches were promoted in Kenyan Maasailand for several reasons (*Swallow & Kamara In: McCarthy, et al., 2000*):

- To prevent encroachment into pastoral territories from small-scale farmers;
- To promote efficient use of rangelands;
- To stimulate investment in rangeland development; and
- To encourage pastoralists to market a larger percentage of their animals.

“It was hoped that, overall, the result would be greater offtake of animals and fewer livestock to counter the prevailing trend of overstocking. Group-ranch development began in the mid-1960s and was mostly completed by 1980. Groups of Maasai men were registered as the legal owners of individual tracts of land ranging

from 50 to 1,000 km² (Galaty, 1992 *In: Swallow & Kamara In: McCarthy, et al., 2000*)...Some positive results undoubtedly came out of the development of the group ranches for the Maasai living in Maasailand. Individual appropriation of land was scaled down and the influx of non-Maasai (at least for awhile) into Maasailand was stemmed. Development projects funded the construction of some livestock-production infrastructure, such as boreholes, dams, troughs, tanks, pipelines, and cattle dips. Schools, shops, and health clinics were also established (Ruttan, 1995 *In: Swallow & Kamara In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute)".

Despite this, heavy investment, stocking rates, herd mobility, and marketing behavior did not change significantly.

Indeed, Homewood (1993 *In: Swallow & Kamara In: McCarthy, et al., 2000*) reports that,

"after 20 years of group ranches, there are no significant differences in livestock production, wealth, or human nutrition between the Maasai in Kenya and their counterparts in Tanzania. Negative results commonly noted include the following:

- Poor project implementation;
- Reduction in the power of customary authorities without the development of an appropriate substitute;
- Divergence between the boundaries of group ranches, customary land management units, and ecological units; and
- Elimination of customary property rights without the development of appropriate substitutes (Kituyi & Kipuri, 1991 *In: Swallow & Kamara In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute)".

According to Parker (2005a),

“membership was supposed to pass from father to one son, to avoid endlessly expanding pyramids of more and more members with shares of less and less value. It hasn't really worked. Here and there Group Ranches have hung together, but there are many who simply could not run themselves as ‘cooperatives’. Here, they have subdivided the land into smaller and smaller parcels. With subdivision, the pressure to move out of stock dependence and towards arable practice automatically rises. Here is where the opportunity to sell to outsiders arises...Substantial swathes of Maasailand have substantial arable potential: a great deal of Kenya's wheat is grown in them. Between Nairobi and Kajiado, there is spreading arable farming. At Bissel white farmers have bought land and produce crops. The basis of this expansion by arable farmers into Maasailand is all on a willing buyer/leaseholder - willing seller/lessor basis. Yes, there have been conflicts, but these, to date, are exceptions...Many Maasai are not good farmers and the incentive to sell land is strong: and so they become landless and drift. Yet, while the quotient of such drifters is significant, there is a significant sector who are adapting to farming and cash economies. You don't hear much about them because they have nothing to bitch about. The vocals are those who have lost, failed, been educated but cannot find employment, the 2nd, 3rd and 4th sons who, to keep body and soul together become night watchmen in Nairobi...Do the Maasai feel hard done by? Yes, there are sectors of Maasai society who seem to be destined to be Nairobi's night watchmen (*askaris*), but this is as much, if not more, the product of evolution within Maasai society, than induced by other tribes. There are human density thresholds for nomadic pastoralism; there are human density thresholds for sedentary pastoralism; and there are thresholds beyond which it is imperative to switch dependence from secondary to primary productivity.⁶⁸ The Maasai expansion has been sweeping them across these thresholds before they can come to terms with each set of new

⁶⁸ It is believed that Ian Parker meant to say from “*primary to secondary*” productivity. It could mean either, and both make sense. Going from primary to secondary implies transformation of primary products employing large numbers of people (e.g., cheese and yoghurt processing plants, pasteurized milk for urban centers, etc.). On the other hand, it could mean moving from livestock (secondary productivity up the food chain) that consume grass and are in turn fed upon by humans, to growing wheat and maize (primary productivity moving down the food chain) fed upon directly by humans. The latter scenario is a trend in Maasailand of both Kenya and Tanzania.

conditions. Population and land tenure in Maasailand are very unstable”.

This has resulted in Kenya’s main tourist attraction, Maasai Mara, facing a crisis of ecological unsustainability (Cheeseman, 2002).

“While the theory behind the Group Representatives Act (of 1969) was to try to formalize existing pastoralist range land management systems, which are based on sociologically and ecologically viable land units, the reality of implementation has been quite different and has been characterized by (Barrow, *et al.*, 2000):

- An emphasis on boundaries, rather than on ecological and social viability, and not necessarily based on customary rangeland management systems;
- The group ranch committees often failing to function as they should have, being dominated by elites sometimes to the exclusion of the actual managers of the land and grazing. Elections were not held as regularly as they should have been; and
- Loans which rarely benefited the majority of members, nor the group ranch in general”.

According to Parker (2004), the roots of the group ranch concept lie in the colonial highland agriculture experience (e.g., Kikuyu farmers) and were championed by the UN Food and Agricultural Organization (FAO) of the United Nations for pastoralists right after independence in 1963. Parker (2005b) states the reasons Kikuyu cooperatives function better than group ranches are that:

- The Kikuyu were culturally closer to the idea of private land ownership than the Maasai, and readily adopted the idea thrust upon them following the dying days of the Mau Mau (see Chapter 3, Section 3.11.1, Population, Kikuyu and the Mau Mau);
- The Kikuyu worked closer with the white settlers than any other group and were avid students of their ways;

- The Kikuyu had high standards of farming;
- Their cooperatives were modeled after white cooperatives such as the Kenya Farmers' Association (KFA), or those in the USA, Australia, South Africa and New Zealand in which private landowners came together to market their produce and purchase supplies cheaper in bulk;
- The largest Kikuyu cooperatives were linked to tea.

“There are some co-operatives in which a group ganged together and bought out a white farmer/rancher, then subdivided it into members' plots. Few of these hung together to farm co-operatively. However, if you are seeking the prevailing Kikuyu 'ethic' - it is strongly towards being an independent individual doing his/her own thing” (Parker, 2005a).

There are also the predominantly Kamba Machakos Cooperatives in which ranches are run as economic units and not subdivided by members and which have been successful in running cattle and wildlife (Nyika, *pers comm.*). Barrow, *et al.* (2000) aptly sums up this issue:

“As a result of the many problems facing group ranches, and the politicization of land tenure in Kenya, there has been a push to privatize such lands in the past 10 years. This has resulted in fragmentation, and loss of access to critical seasonal grazing areas, water and salt. Owners now had, but did not necessarily understand the consequences of individual tenure. As a result land was sold, and many poorer pastoralists were marginalized from pastoralism, while the richer and more powerful consolidated and expanded their holdings. In addition outsiders have now been able to acquire such lands”.

“The concept was to divorce Maasai society from communal land tenure in which the bottom line was rule by the lowest common denominator (the Achilles heel of socialism) by giving tenure to identifiable groups who, through ownership, etc. would manage their land better, have assets upon which to raise capital - which had worked extremely well with, for example, the Kikuyu. The application was flawed. Is a group of say 1,000 families all owning shares, really an advance towards private tenure? Isn't it little more

than a pastoralist commune in which the lowest common denominator still rules? And then there was the allocation of the actual group ranch boundaries that gave some wet season ranges and others dry season ranges (here I exaggerate to make the point)...In historical perspective - the group ranches have been no more than a staging post in the drift towards private tenure. Not one has been well managed as a ranch. Some have been less badly managed than others - that is all. As might have been predicted, the more enterprising and ambitious of the ranch members came to the fore at the expense of those lacking these qualities...Pressures arise to subdivide group ranches, the best bits - invariably those with arable potential - naturally going early. The trend of the least able being left on the least desirable land is a product and the cycle is completed when unable to make ends meet, they sell off to the more affluent - and it's the rise of the cattle barons all over again. At that point, economically viable ranching land units will appear - at which point long-term planning will become reality...Group ranches are a halfway house between genuinely communal tenure and private holdings" (Parker, 2004).

Of course, this means that the traditional lifestyles for the majority of the Maasai are on their way out, if not already gone.

Before, during, and after the development of the group ranches in Kenya, many Maasai expressed a demand for individual title deeds (Swallow & Kamara *In: McCarthy, et al.*, 2000).

"Individual titles were first granted for better-watered areas (e.g., Kapiti Plains/Kaputui) close to the urban center of Nairobi. As problems with the group ranches emerged, group ranches were subdivided and areas that had not previously been adjudicated into group ranches were individualized" (Grandin, 1991 *In: Swallow & Kamara In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

According to Nyika (*pers. comm.*), land must be adjudicated (legally allocated) before it can be individualized/subdivided. By 1990, owners of 40 of the 51 group

ranches had decided to subdivide their land (*Swallow & Kamara In: McCarthy, et al.*, 2000). According to Mike Norton-Griffiths (2007), land is subdivided for three main reasons, 1) security from in-migration, avoiding capture by elites and NGOs wishing to confiscate more communal lands for conservation, 2) dilution of communal benefits with population increases and 3) to capture benefits at household level. As this land is subdivided, wildlife that needs large open spaces is crowded out. Ruttan (1995 *In: Swallow & Kamara In: McCarthy, et al.*, 2000)

“conducted research in 2 of 7 subdivided ranches in Kajiado District. In Okinos, the average ranch size was 47 ha, while in Embolioi the average ranch size was 93 ha. Former members of the group-ranch committees obtained ranches twice as large as those received by ordinary members” (Excerpted with permission from the International Food Policy Research Institute).

According to Parker (2005a), “then there is the Maasai inability to cohere which is a source of derision across the rest of the country. Group Ranch Chairmen rip off their members wholesale; County Councilors and MPs do likewise. As a group the Maasai are about as disputatious as it is possible for people to be. I don't think that this is a genetic characteristic so much as the product of their circumstances. But it is a feature that makes them vulnerable to more organized interests”!

“Between 1986 and 1990, more than 33% of all those holding titles had applied for further subdivision of their land for sale to other parties. Ten percent (10%) of all title holders had transferred a total of 2.4% of all of the land. Of the 37 plots sold, 84% were purchased by non-Maasai. Nominal land prices increased nearly 10-fold between 1986 and 1994” (Ruttan, 1995 *In: Swallow & Kamara In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

“A smaller number of pastoralists (2.2% of title holders) had mortgaged their land to receive loans. Very little had been invested in fences, boreholes, or other capital. Most of the proceeds from the sale of land apparently were invested in the construction of modern homes. Thus it seems that the demand for individual titles to rangeland is driven by three main factors. First, the parts of Maasailand with good overland connections to Nairobi, with good

soils, and that receive good rainfall are of high value in non-pastoral land uses. Second, actual demand has resulted in a speculative demand for less-favored areas. Third, people observe that national policies favor private property over common property. The incentive to increase individual investments in grazing land does not appear to be a major factor" (Swallow & Kamara *In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

Amboseli

In 1906, under colonial rule, the 27,700 km² Southern Game Reserve, which includes present-day Amboseli, was created. In 1948, the reserve was reduced to 3,260 km², named Amboseli National Reserve and placed under the administration of the National Park Trustees. In 1961, it became a County Council Game Reserve administered by the Olkejuado (Kajiado) County Council. In 1971, a Presidential Decree declared that the 390 km² surrounding the main swamps in the ecosystem be used exclusively for wildlife and tourism. Since October 1974, Amboseli has been run as a national park by the Kenya Wildlife Service (KWS) and preceding government bodies (Moss, 2005).

Originally touted as a success story with a core protected area and surrounding buffer with watering points for cattle (Ledec & Goodland, 1988 *In: Colchester*, 1994), the Amboseli National Park and environs have become zones of conflicting land uses. Beginning around 1981,

"the water supply system began to deteriorate. Compensation fees went unpaid. The school was inappropriately located. Little tourism developed outside the park. Royalties accrued to central government and the local district council but failed to trickle back down to the local level" (Peluso, 1992; Hannah, 1992 both *In: Colchester*, 1994).

The Maasai have been unhappy and disgruntled ever since (Moss, 2005).

Since only 1% of the gross revenues from the Amboseli National Park in 1990 went to the peripheral Maasai communities (Emerton, 1998) and as a result of the government policy of subdividing group ranches, many of the young Maasai wishing to enter into a market economy sold or leased critical dry season grazing land to small-scale farmers. The community revenue from Amboseli amounted to US\$ 150,000 in 1990 out of US\$ 15 million of wildlife revenues (Norton-Griffiths, 1996 *In: Barrow, et al.*, 2000).

In many cases, once individual ownership of land existed, bank loans were taken out against the land, which were not paid back. The bank foreclosed or confiscated the land, often selling it off to small-scale farmers. Many Maasai became landless and started wandering with their herds, which often resulted in conflicts with those still holding land (DeGeorges, 1991). The loss of dry season grazing habitat around Amboseli from the sale to small-scale farmers, has forced both wild and domestic animals into the Amboseli National Park during the dry season, strongly contributing to the degradation of this park as its carrying capacity to support herbivores has been exceeded. Airline passengers flying from Nairobi to Mombassa or tourists driving from Loitokitok to Amboseli can see a bright red cloud of dust over the park. This dust is raised by the destruction of vegetational cover from the unnatural concentration of wildlife and livestock during the dry season, and excessive vehicular traffic from mass tourism (DeGeorges, 1991). Despite all of this, it is argued that the Maasai still maintain a positive attitude towards wildlife. Despite all of the land use changes, wildlife populations in the Kajiado District, where Amboseli is found, have decreased by only 15% over the last 20 years; numbering 175,260 in 1977 and 148,770 in 1994 (Grunblatt, Said, *et al.*, 1995; Rainy & Worden, 1997 both *In: Barrow, et al.*, 2000). This compares to losses in wildlife numbers of from 40-80% in other rangelands in Kenya (Barrow, *et al.*, 2000).

Elephant researcher Cynthia Moss's Amboseli Trust for Elephants has been trying to make up for failed promises from the Kenya Wildlife Service (KWS) (Moss, 2005):

- Making livestock consolation payment scheme since 1997 for cattle, sheep and goats killed by elephants;
- Giving scholarships and living expenses for Maasai students from Amboseli to attend university;
- Giving scholarships for girls to go to secondary school;
- Giving employment to seven research scouts, a Maasai liaison officer, camp workers, and research assistants from the local community;
- Helping local people find jobs in tourism and wildlife;
- The Trust's project manager is a member of several committees set up to deal with Maasai issues; and
- Supporting a major project trying to find ways to alleviate human-elephant conflict where Maasai have started to farm.

In a surprising, bold and some say a political move to get the Maasai vote for the draft Kenyan constitution (Obat, 2005), President Mwai Kibaki signed a decree on September 29, 2005, which officially degazetted the Amboseli National Park, turning it over to the Olkejuado County Council to be run as a national reserve. Gate receipts and other revenue will go to the County Council instead of Kenya Wildlife Service (KWS) that runs the national parks.

“The rules and regulations for reserves are more flexible regarding human activities within the boundaries, whereas conservation and tourism are supposed to be the only activities within National Parks” (Moss, 2005).

Various conservation groups are contesting this change saying it is in violation of the Wildlife Conservation and Management Act (Obat, 2005). These groups include the East African Wildlife Society, the Youth For Conservation, the Centre for Environmental Legal Research and Education, and the Born Free Foundation. They have taken the matter to court and temporarily suspended the resolution contained in a legal notice dated September by Tourism minister Morris Dzoro to downgrade the Amboseli Park (Kadida, 2005). Time will tell whether this bold step proves beneficial to peripheral Maasai or, as will be seen below with Maasai Mara, whether it will be a source of power and income to be misused by a few elites within the Country Council. However, it would seem to be the correct direction to take. Concern has been raised about a lack of trained personnel to run the reserve (Moss, 2005), a problem throughout Sub-Saharan Africa. On the positive side, devolution of tenure over the land and resources to the Maasai could help reverse the 20th century trend where the human population, alienated by the elitism of conservation, has accelerated the conversion of Sub-Saharan Africa's natural areas into man-made systems (e.g. pastures and farms). The referendum on proposed constitutional changes was defeated in November 2005 (Mageria, 2005), resulting in further political and economic upheaval. In early 2006, massive corruption scandals, involving a number of ministers, have come to a head.

Maasai Mara

"In 1988 the 122,500 visitors to the Maasai Mara National Reserve accounted for over 10% of all tourist bed nights in Kenya. In addition to spending money on accommodation and Reserve fees, tourists also directly supported a range of other enterprises, including balloon safaris, sales of handicrafts and various travel and transport-related purchases. Total tourist expenditure for the area was over US\$ 26 million. However, although almost twice as many tourists visiting the Maasai Mara stayed - and most wildlife was found - on communal lands rather than in the Reserve, less

than 1% of cash income accrued to local Maasai and under 10% remained in the District as (local county) Council revenues or wages to local employees" (Emerton, 1998).

Simultaneously, a sudden demand for wheat and barley by Kenya's new middleclass inspired investment in Green Revolution technologies. This resulted in the conversion of land in an area that had been considered too dry for agriculture, making the Narok District Kenya's leading producer of both wheat and barley by the mid-1980s (Cheeseman, 2002). The average Maasai, seeing no value in wildlife, opted out by selling or leasing his land to commercial wheat schemes. These wheat schemes increased from 404,858 ha (1 million acres) in 1981 to 1,214,575 ha (3 million acres) by 1992 (Bonner, 1993). Many of these areas are critical rainy season dispersal areas for wildlife in the Mara. Large numbers of wildlife that disperse out of the Mara are shot as problem animals. One farmer alone shot 3,000 head of game in one year (Bonner, 1993). Dry season habitat is the bottleneck to carrying capacity for both livestock and wildlife. The agricultural potential here is greater than that for either livestock or wildlife tourism (Parker, 2004). Similarly, just across the border in the western Serengeti of Tanzania, "wildlife populations continue to decline as farmers continue to clear land for cultivation rather than wildlife" (Emerton & Mfunda, 1999 *In:* Roe, Mayers, Grieg-Gran, Kothari, Fabricius & Hughes, 2000) (Also see, Section 9.7.8.2, "Politics of despair", Southern Maasailand "Tarangire Ecosystem", where seeing little value in wildlife, critical rainy season dispersal areas are being over-grazed with livestock, or converted to small and commercial farms with the net result that there has been a major reduction in wildlife within the system).

Overall, in Kenya, it is estimated that "large herbivores in the rangelands have declined by 40–60% between 1977 and 1994" (Child, 2005 *In:* Lyman & Child, 2005). Ottichilo (1996 *In:* de Haan, *et al.*, 1997) reported a 30% decline in

Kenya's wildlife populations as a whole over the last 20 years. Norton-Griffiths (2007) estimates the total loss of large wildlife in Kenya since 1977 at 60-70%, with equal amounts being lost within and outside of protected areas.

Game populations in the Narok District have declined by 32% between 1977 and 1994, from 522,588 to 356,679 (Grunblatt, Said, *et al.*, 1995; Rainy & Worden, 1997 both *In:* Barrow, *et al.*, 2000). Within the dispersal areas of the Mara ecosystem, wildlife populations declined between 1977 and 1993 from 217,871 to 66,535, respectively and then started to increase between 1994 and 1996 to 130,242 and 243,374, respectively (Barrow, *et al.*, 2000). The apparent increases in wildlife in the Mara Ecosystem between 1994 and 1996 in Barrow, *et al.* (2000) may not be because of community involvement, but due to compression (loss) of the wildlife habitat, forcing wildlife to concentrate into smaller areas (Barrow, *et al.*, 2000). Waithaka (2004) describes the following tendencies with regard to wildlife populations within the Mara Ecosystem⁶⁹ that show a consistent decline as opposed to the fluctuating numbers in Barrow, *et al.* (2000):

- 56% overall decline in wildlife for most species in the last 20 years;
- White-bearded Wildebeest (*Connochaetes taurinus albojubatus*), 81% decline, 1977-97, especially in the Loita plains – the main calving and breeding grounds that have been converted to wheat fields;
- Cape Buffalo (*Syncerus caffer caffer*) decline from 15,400 in the 1970s to 3,000 in 1994;
- Eland (*Taurotragus oryx pattersonianus*) from 5,700 in the 1980s to 1,025 in 1996;
- Kongoni/Bubal Hartebeest (*Alcelaphus buselaphus cokii*) from 4,150 to less than 1,400 over the last 20 years;

⁶⁹About 80% of the Mara ecosystem is found in the Narok District (Nyika, *pers. comm.*), the remainder being in the Trans-Mara District

- Topi (*Damaliscus korrigum*) declined from 20,748 in 1988 to 8,900 in 1996;
- Warthog (*Phacochoerus aethiopicus*) decline by 88% from 1988-1996; and
- 72% decline in giraffe (*Giraffa camelopardalis*), common waterbuck (*Kobus ellipsiprymnus*) and other antelope from 1988-1996.

This decline can be attributed to land use change and habitat fragmentation, particularly in the north and northwestern parts of the ecosystem, where wheat and maize production has increased (Barrow, *et al.*, 2000; Waithaka, 2004).

Norton Griffith (1996 *In:* Barrow, *et al.*, 2000) argues along the lines of Parker that the revenues that Maasai Mara generates from wildlife may never be as high as alternative land uses. Group ranches around the Mara are providing hidden subsidies for conservation, as well as the costs of lost production. Conservation managers will have to meet these costs through improved financial arrangements, as the potential value of the land cannot be denied to the owners, and the Maasai cannot be condemned to a perpetual poverty trap in the name of conservation. This implies that wildlife must pay for its existence or risk to have its habitat converted to wheat. This will require wildlife and its many uses to be open to a free-market, and/or the conservation community compensating the Maasai landowners in perpetuity for maintaining their ranches as extensions of the Mara ecosystem. The latter is unlikely, and as Ian Parker feels, it is not evident that wildlife can compete with wheat. In the long-term many of these areas may have to go under the plow to help Kenya stand on its own feet economically and to feed itself.

In Kenya as a whole, Norton-Griffiths and Southee (1995 *In: de Haan et al.*, 1997)

“estimated the foregone revenue from livestock and agriculture from the parks at US\$ 203 million, whilst the revenue from these parks amounted to only US\$ 42 million”.

Norton-Griffiths (*pers. comm. In: Magome & Fabricius, 2004 In: Fabricius, et al., 2004*) suggests that once the mean annual rainfall exceeds 600 millimeters, wildlife will have a difficult time out-competing the same land converted to agriculture. Sad but likely true! In fact, it is estimated that more than 50% of Kenya’s higher potential land (>700 mm annual rainfall) has already been converted to agriculture that displaces wildlife, but is inclusive of livestock (Norton-Griffiths, 2007). In addition, as currently practiced (e.g., little or no sustainable use, especially trophy hunting), Norton-Griffiths (2007) estimates that

“average returns to wildlife of US\$ 10 ha/yr are competitive with agriculture only in very dry areas of below 300 mm of annual rainfall, and with livestock below 600 mm annual rainfall... (in fact) net returns from livestock could be some 66% higher were wildlife to be eliminated” (for additional comparisons of wildlife versus livestock values see Chapter 9, Section 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa and for displacement of wildlife by farms and livestock see Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

According to Child, Castley, Knight, Gordon, Daitz, Johnson, Boonzaaier, Collinson, Davies, Grossman, Holden, Kiss and Fernhead., (2004 *In: Child, B., 2004a*) resource management of the core tourism area, the Mara Triangle, was contracted out to Mara Conservancy Pvt., Ltd. responsible for managing 34% of the gate revenue based upon monitored performance criteria. However, members of the County Council are not entirely committed to this change as it results in a loss of influence and patronage opportunities. This is a legal arrangement between the Trans-Mara County Council and the private company. The Mara

Conservancy collects gate receipts, maintains infrastructure and anti-poaching among other activities. The goal of this relationship is to stem the loss of money from corruption. Members of this company are non-Maasai and non-resident of the area, but are Kenyans. Concern exists that any gain in revenue from stemming corruption by this conservancy group is taken out of the area in salaries and fees paid to this company, with little or no increase in benefits being seen by the average Maasai (*Nyika, pers comm.*).

In many areas of Kenya, a combination of the above-noted factors is resulting in major tension between pastoralists and farmers. A combination of land compression among both the Maasai and Kikuyu during the colonial era, the population explosion of the 20th century, and poorly thought out land tenure policies (group ranches) has resulted in major conflicts between land-hungry Kikuyu farmers who moved into the Narok and Kajiado Districts, especially Loitokitok and Kaputei in Kajiado District, as described above, and the Maasai (Figure 5.6). In October 1993, about 30,000 Kikuyu were chased out of a Maasai area, Enosupukia (between Nairobi and Narok) and 20 people died (Richburg, 1994). Parker (2005a) attributes part of this problem to the close ties between the Maasai and Kikuyu.

“Their biggest difference is linguistic - the Maasai speaking a highland Nilote language, and the Kikuyu a Bantu tongue of the north-eastern Bantu group...The structure of society was similar, customs were broadly similar, shield patterns, age sets, weapons and military tactics had a great deal in common. Some Kikuyu “*mbari*” (sub-clans) had Maasai founders. The great Maasai leader Batiaan had a Gikuyu name - Mbatia wa Gaterimu - and the Kikuyu say he was born a Kikuyu on the Chania. While it may not be entirely correct, viewing the Kikuyu as agricultural Maasai, is at least as accurate as seeing them as Bantu and possibly a little better. The consequence of this is that there is and has been very substantial intermarriage between Maasai and Kikuyu. This is extending arable farming deep into Maasailand and intermarriage between educated Maasai and Kikuyu is probably higher now than

at any time past. My point, a clear cut division between the two groups does not exist and is continually eroding" (Parker, 2005a).

These conflicts are ongoing. According to Nyika (*pers. comm.*), similar conflicts existed in 2004/5 between Maasai and Kamba in the Kajiado District, the Maasai and Kikuyu/Kalenjin in the Narok District, the Maasai and Kisii in the Trans-Mara District, the Samburu with Turkana herders moving South into the Baragoi Division of the Samburu District, and Samburu herders moving onto white ranches in the Laikipia District during droughts, which have been frequent in recent years. Land and resource access, as well as land use and tenure are and will continue to be major sources of conflict and threats to the future of wildlife in Kenya. Majtenyi (2005) describes the continual clashes over land and water between the Maasai and Kikuyu in the Rift Valley.

The late 2007/early 2008 flare up between Kikuyu and other ethnic groups over whether the Kikuyu, through President Mwai Kibaki of the Party of National Unity (PNU), won free and fair elections against Raila Odinga, a Luo of the Orange Democratic Movement (ODM), has resulted in over 650 deaths by mid-January (Wadhams, 2008), some say 1,000, and 250,000 internally displaced people (VOA, 2008). The disputed presidential election may have been the proximate cause, providing oxygen to the burning embers, land and resource scarcity being ultimate causes among others such as high unemployment, poverty, terrible urban slums, and a struggle between ethnic group(s) to control power and thus privileged access to land, jobs and other resources. Much of the conflict pits Kikuyu that make up 20% of the population against other tribes, especially Luos, Luhyas and Kalenjin (Wadhams, 2008) over the skewed distribution of land to Kikuyu's, associated with President Jomo Kenyatta, 45 years ago at independence (Latham, 2008). Parker (2008) contends that Odinga is a socialist that the Kikuyu will never accept, who wishes to end freehold/private land tenure of the 4 million title deed holders, 99% black and most, but not all, Kikuyu. The worst violence is

occurring west of the rift where Kikuyu were settled on former white-owned farms during the Kenyatta era, where Kalenjin who feel robbed of their land, are fighting Kikuyu. Strife in Western Kenya is purely ethnic cleansing of mostly successful Kikuyu shopkeepers, land not being the major issue, but envy.

It is believed that over much of Sub-Saharan Africa today, these internal conflicts over scarce resources may be as serious as large-scale civil wars on the subcontinent, with little or no coverage by the international press (see Sections 5.11.2, Over-population, Desertification and Instability, Nigeria and 5.11.4, Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics). According to the Commission for Africa (2005) countless smaller conflicts, which are no less vicious, such as those between herders and cultivators, are to be found in many parts of Africa. Violence causes as many deaths in Africa as does disease. Eventually, smaller conflicts can lead to civil or regional wars. For instance, one might ask how much of the conflict between Rwanda and the DRC is over the need for land by an over-crowded Rwanda, which suffers continually, along with Burundi with internal conflicts over scarce land/resources. These conflicts have become ethnically divided when the resource to people ratio becomes significantly reduced (see Section 5.9.4.6, Deforestation in afromontane forests; Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Political Destabilization)?

Kenyan conservation is intimately tied to the Maasai and how they utilize their land. As human populations increase, the net result of decreased fallow, in addition to soil degradation, is expansion onto marginal lands by small-scale farmers, in this case Maasai lands by Kikuyu farmers. This results in increased conflicts between pastoralists and farmers, declining wildlife habitat and a net decrease in available land per capita throughout Sub-Saharan Africa. Norton-Griffiths (2007) argues that the entire economic system of rangeland production in Kenya has undergone a radical transformation since the mid-1970s: the human

population growing at >3%/yr; cultivation growing at >8%/yr; livestock numbers remaining stable, even with offtake growing at >4%/yr; and wildlife decreasing by >3%/yr per annum. It is interesting to note that there appears to be a direct relationship between the increase in human populations and the decrease in wildlife (large herbivores). Other than South Africa, Namibia and to some degree Botswana, where wildlife has value to the landowner (see, Section 5.12.7, Attaining Food Security through More Appropriate Land Use Options, Wildlife as a Land Use Option on Marginal Lands), this relationship is a trend across the subcontinent. For additional discussion on this issue, see Chapter 10, Section, 10.4.5 Does CITES Help Southern African Elephant Conservation?

Meanwhile, Kenya Wildlife Service (KWS) policies do not endear rural Kenyans to wildlife. Although group ranches in the area, can apply to the Kenya Wildlife Service (KWS) for wildlife utilization rights, this requires demonstrating the ability to manage wildlife, undertaking game counts, having access to a veterinarian approved abattoir, etc.

“To make wildlife a viable land use option, extensive range areas are required. Communities and land users have responded to this by organizing themselves into Wildlife Associations, Forums, Conservancies and Trusts” (Barrow, *et al.*, 2000). According to Barrow, *et al.* (2000), the “pilot wildlife use rights” program, currently in operation in Laikipia, Machakos and Nakuru Districts, is a clear demonstration of how, in some places, communities who have wildlife on their private land, can earn money through their own enterprises on a long-term, sustainable basis”.

However, even in those few areas with user rights, most income comes from the sale of meat, which, with veterinary restrictions, is limited to sale in Kenya. Only a few outlets, such as the Carnivore Restaurant, are willing to pay premium prices for game meat. Game products made from horn and skin are illegal to sell as souvenirs, while game skins cannot be tanned with hair on. The added value of

transformation is obtained by other countries, such as South Africa and Botswana, who purchase all the zebra skins they can get their hands on. Minimal income can be earned from game bird shooting. Game bird shooting is so minor as an economic resource, in the early 1990s, when the principal author lived in Nairobi, he was given a permit to shoot ducks, without limit as vermin, Problem Animal Control (PAC), on the Mwea Rice Scheme. In recent times, there have been attempts to market Kenya's excellent bird shooting. However, without overseas trophy hunting, stopped in 1977 under pressure from the World Bank and other donors, combined with the above activities, group and private ranches can only ever make minimal income from wildlife, with no real incentive to conserve it or its habitat (see Chapter 9, Section 9.6.1.2, Kifluku Farm, Laikipia, Kenya).

Norton-Griffiths (2007) identifies the decline in Kenya's wildlife despite hundreds of millions of dollars provided by the international donor/NGO community due to three areas:

1. policy failures, including wildlife tenure by private and communal landowners, most importantly a failure to fully accept consumptive use including hunting that disenfranchises 95% of the pastoral rangelands; wildlife tourism being restricted to only 23,000 km²/5% of the rangelands where wildlife are found;
2. institutional failures including the Kenya Wildlife Service (KWS) claim of ownership over all wildlife and biodiversity, its role as a regulator and policeman instead of a facilitator to encourage wildlife as an economic resource and best land use in low rainfall areas by landowners other than itself, and communal institutions often being controlled by elites with the result that they fail to meet the needs of ordinary members, and
3. market failures, especially private sector tourism cartels that keep the lion's share of the profits, landowners (including KWS, county councils and private landowners) capturing only 5% of the total revenue generated by wildlife.

In addition to devolving ownership of wildlife to landowners - assuring their right to benefit from wildlife, development of negotiating skills that allow communities to capture more of the wealth from wildlife during contract negotiations, and

compensation for wildlife damage to landowners, Norton-Griffiths (2007) recommends the adoption of what he calls private sector conservation (PSC). This is basically the Southern Africa model, where the landowner controls access over and determines how he/she uses the wildlife as an economic resource in a free-market, with certain limitations regarding animal welfare, biodiversity and ethics (see Chapter 3, Section 3.5, DEVELOPMENT OF HUNTING ETHICS IN AFRICA and Chapter 9. Section 9.8.3, Devolution on Private Game Ranches, Southern Africa, Short-Term Success, Long-Term Failure?). He places much of the blame on Western NGOs for wasting money and failing to adopt this economic wildlife model. For additional discussions, see Chapter 11, Section 11.11.9 Kenya Wildlife Service (KWS) – Living on Donor Handouts, Negative Impact on Kenya's Wildlife Outside Parks.

5.7.1.4 Land tenure in Laikipia, Kenya

As discussed in Chapter 3, Section 3.8.4, Land Compression and the Maasai Of Kenya and Tanzania “on August 15, 1904, the Maasai signed a treaty with the British colonialists leasing to the British about 1,000,000 ha of land in Laikipia district for 100 years. British settlers subsequently moved onto the land and set up large ranches that remain there to this day” (Majtenyi, 2004a). The expiration of the lease in August 2004 was marked by a series of demonstrations and land invasions by Maasai herdsman cutting fences surrounding private ranches. According to Cabinet minister William ole Ntimama, an ethnic Maasai had the following to say,

“ ‘What has really prompted the invasion is the drought and the fact that there is no water outside those fences,’ he said. ‘Those poor pastoralists are totally desperate. They do not know what to do when they see dams and pipes of water just next to the land and they see good grass and they are suffering, their cattle are dying of drought, and they themselves are hungry and some of them could be dying’ ” (Majtenyi, 2004a).

On August 25th, 2004, the public service minister urged the Kenyan government to pay the Maasai US\$ 123 million as compensation for the land that had been leased to the British. The Kenyan government has refused demands by the Maasai for the return of their land on the grounds that the lease by the Maasai to the British is for 999 years not 99 years, property laws since independence override colonial agreements and that if the lease ends, the land comes back to the Kenyan government. They are concerned that the land issue could destabilize relations between Kenya's 40 ethnic groups, and spark an uncontrolled re-occupation of land as various leases expire (Majtenyi, 2004a). For instance, because of a similar 99 year lease agreement expiring with the British, the Sabaot community threatened to invade farms in the North Rift region extending from Murukujit in West Pokot to the Kimilili Constituency to the west and again from the River Suam at the Uganda border to the River Nzoia in the Uasin Gishu districts of Kenya (Maero, 2004).

Most of the Laikipia ranches are owned by whites, either the descendants of British colonials and/or wealthy outside investors, increasingly Western conservation NGOs, and some high ranking Kenyan politicians and military officials. The Kenya Land Alliance believes that the skewed distribution of land in Kenya must be addressed as planned under the draft constitution. Maasai activists are prepared to take their case to the Kenyan High Court and the International Court of Justice to get their land back (Majtenyi, 2004a).

5.7.2 Creation of Parks and Protected Areas, a Constraint to Good Land Management

Gazetting lands for parks and protected areas increases tenurial insecurity for those living in environmentally sensitive areas and is a major disincentive to investing in sustainable agricultural intensification. The bitter irony is thus that pressures for environmental conservation (e.g., the IUCN goal of seeing 10% of

Africa's land mass in parks and protected areas) may induce environmental degradation by threatening traditional common property management systems, the land and its resources (Reardon, *et al.*, 1999). Also, as discussed, during colonial times, the creation of such areas without fully integrating the needs of local people into them resulted in land compression and rapid degradation of resources in peripheral areas, plus the alienation of rural Africans towards protected areas. This turned protected area resources into unmanaged "open access" regimes that were poached and mined for short-term gains. The risk is that these parks and protected areas will become hard-edged, that is surrounded by masses of alienated humanity living in poverty who will eventually, in trying to survive, destroy the very natural systems that are in need of protection (see Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers and Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas).

5.7.3 Lack of Planning as a Constraint for Agricultural Production

There is a general lack of land use planning in Africa, both for the development of urban and rural environments. There is a need to identify crucial commercially viable agricultural food-producing land and to develop long-term plans to assure that this land is maintained in commercial food production to feed the growing urban masses. This will become necessary in order to prevent Sub-Saharan Africa from becoming dependent on donor food aid and in return susceptibility to political manipulation by the West, already a growing problem.

"As the population growth and the demand for suitable agricultural land increases, there is need for a planned assessment of agricultural potential in Africa. Soil taxonomy provides a basis for assessments of soil resources, especially using small-scale regional maps and more detailed national and local assessments. The information, when incorporated into a Geographic Information System (GIS), becomes more useful by providing greater

analytical capabilities and facilitating the creation of interpretive maps. Data can also be manipulated to give a 'best guess' where data is scarce or of unknown quality, as is often the situation in Africa. With socioeconomic and other data layers, realistic national assessments and appropriate strategic plans can be developed" (Eswaran, *et al.*, 1996).

5.7.4 Land Reform/Redistribution without Integrating Local Communities as a Constraint to Agricultural Production

Land reform is primarily an issue in Southern Africa, where comparatively large numbers of descendants remain from original settler colonies, controlling a majority of the good agricultural lands. Without land redistribution on a significant scale, millions of smallholders in Southern Africa will face a very grim future unless there is increased off-farm employment in urban centers to diffuse this pressure and demand for land. Certainly in "today's Africa", many of the youth prefer the allure of bright city lights, especially once provided with a Western Education.

"Top-down land redistribution offers the prospect of limited change – bogged down by expense – that does not significantly improve economic and social opportunities because it ignores smallholders' understanding of the conditions under which land can contribute to improved livelihoods. Exclusively market-based redistribution will not necessarily mean improvement in access to land among the rural poor (although it may increase overall agricultural resource-use efficiency). There is an urgent need to bring the smallholder voice into the process – not only with regard to the "whether" of land reform, but also the 'how'...the situation in parts of southern Africa is now favorable for land redistribution, to the extent that the economic value of this asset to the large-scale current owner is low or declining. In Zimbabwe, a significant portion of the land held by commercial farmers is/was unused...In Namibia and South Africa, the economic value of many large holdings has declined as a result of the elimination of subsidies (which have always been captured, throughout the region, much more by large-scale farmers than by smallholders). In Malawi, the value of estate land is probably declining as market access privileges are eroded. In such circumstances, there may be a solid

basis for the application of the ‘willing buyer, willing seller’ principle” (IFAD, 2002).

Once land is distributed, education and extension become key, if small-scale farmers are not to degrade once productive commercial lands. Keeping land redistribution apolitical will also be a key to success. There are few models of successful large-scale land transfer in favor of smallholders in the region (IFAD, 2002).

Land reform is primarily a southern Africa issue. Land reform, to rectify its inequitable distribution between white and black Zimbabweans, became radicalized as a means of President Robert Mugabe and his political party Zimbabwe African National Union – Patriotic Front (ZANU-PF) staying in power. This has had adverse impacts on food production, conservation, utilization of wildlife, and both national and regional economies. Poorly thought out internal and regional policies that result in economic ruin and uncontrollable immigration by the poor, hopeless disenfranchised masses could end any hope for an “African Renaissance”, and end any hope for Africa’s people to benefit from the technological solutions to development that the subcontinent’s economic engine, South Africa, may have to offer.

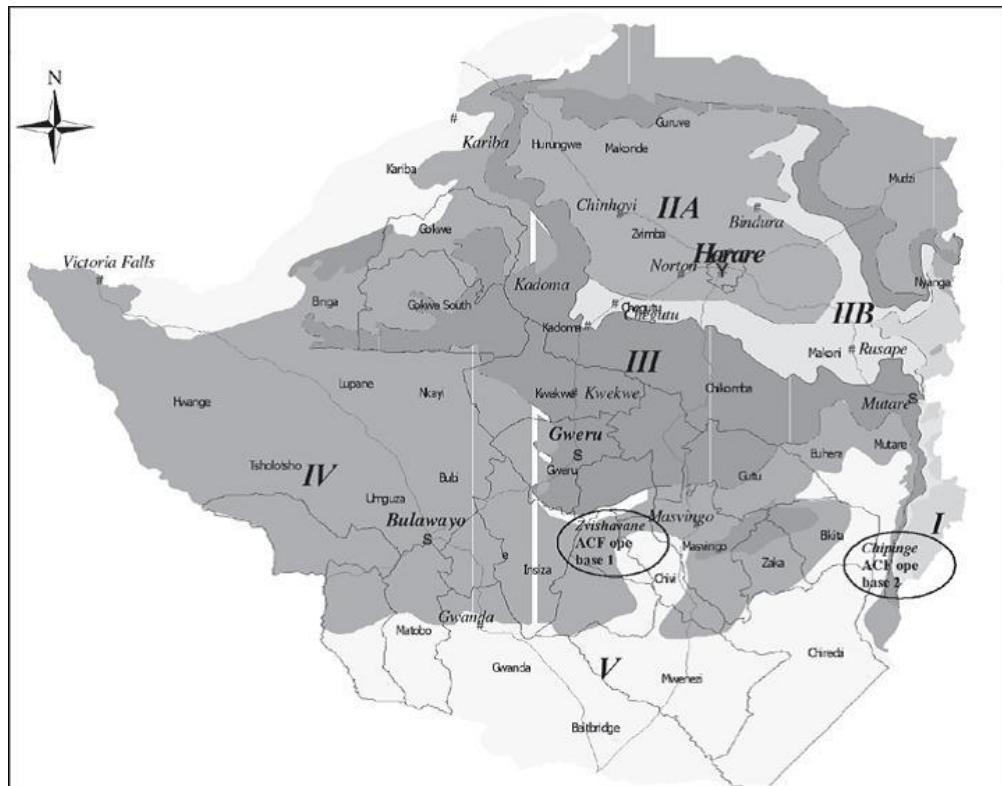

5.7.4.1 Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife

This case study is summarized in DeGeorges & Reilly (2007). The Land Tenure Act of 1969 favored white appropriation of the best agricultural land at a time when the whites made up only 5% of the population. Although the land ownership was evenly split between white and black, approximately 18 million ha for whites and 18 million ha for what were called “*Tribal Trust Lands (TTL)*”,

thousands more blacks were evicted from their lands. What appeared as a move towards equity was just the opposite (Wels, 2000; Meredith, 2002).

- **Allocated To Whites.** Prime farmland, including 75% of the land in agro-ecological Region I and 66% in Region II; and
- **Allocated To Blacks.** The majority of the poorer soiled, unreliable rainfall agro-ecological zones; 74.2% of their land falling in Regions IV and V (Wels, 2000).

The five agro-ecological zones of generalized land use potential are based primarily on the amount and reliability of rainfall (Figure 5.7).

Source: ACF (2006) with permission, Action Contre La Faim (ACF)

Figure 5.7 Agro-ecological Zones, Zimbabwe

About 80% of Zimbabwe averages less than 800 mm rainfall/year, mostly in Regions III, IV and V. These low rainfall areas, where the majority of black Zimbabweans are compressed, are best used for harvesting natural vegetation

from either wild or domestic herbivores, unless supplemented by irrigation. Induced by need, tradition and Government to practice rainfed agriculture (Child, 1995), and with little or no training in modern intensive agricultural practices, the soils of these marginal areas were quickly depleted by a rapidly expanding black population.

White commercial farmers received subsidies in the form of price controls, fodder in droughts, cheap labor, state investments in control of endemic livestock diseases, infrastructure such as abattoirs and fencing, while communal lands were subjected to compulsory destocking, providing livestock to white commercial farmers at below-market prices (Phimister, 1978 *In:* Bond, *et al.*, 2004 *In:* Child, B. 2004a).

At independence in 1980, Zimbabwe inherited a dual agrarian structure of 6,500 predominantly commercial “white” farmers producing 90% of the maize and cotton and 99% of the tobacco, while 700,000 black smallholders produced the remainder. Before the structural adjustment programs of the second half of the 1980s and the first half of the 1990s, the Government developed rural feeder roads and depots to provide reliable market access, subsidized farm credit programs, subsidized fertilizer and seed inputs, and expanded extension services to smallholders - conditions that in the early 1980s, provided the incentive and capacity for smallholders to adopt long-available hybrid maize varieties. Using hybrid maize varieties developed in Zimbabwe, from 1979-1985, Zimbabwean smallholders were producing 30% of the marketed surplus maize (tripling their maize production), up from 10% in 1980. They sold 60% of this increase in maize output. However, 70% of this increase came from only 10% of the smallholders who had the best watered land in higher rainfall areas (Eicher, 1990 *In:* Eicher & Staatz, 1990). Many Zimbabweans also feel that the collapse of industrialization, strongly linked to World Bank and International Monetary Fund (IMF) structural adjustment policies, resulted in massive retrenchments in urban centers, forcing

people back onto the land (Murphree, 2001), exasperating an already existing land hunger in the over-crowded homelands, and the end of government support to many of these farmers.

The white farmers controlled 40% of the country's total land area, including 67% of the country's high potential land, while 700,000 smallholder households were crowded into marginal and degraded TTLs, most of which lay in semi-arid parts of the country or in areas with poor soils. The TTLs were explicitly regarded as labor reservoirs from which the formal agricultural, manufacturing and mining sectors would draw their manpower (IFAD, 2002). On the positive side in 1986, Zimbabwe alone could have made up the 1.6 million ton shortfall in grain needed by 18 Sub-Saharan African countries (Rosenblum & Williamson, 1987). With commercial agriculture and the development of regional infrastructure and markets, Africa can potentially feed itself. Unfortunately, as will be seen, this capability has been destroyed in Zimbabwe due to internal politics and cronyism.

Fighting over Fences

A major issue facing land reform in Zimbabwe and the rest of Southern Africa is the significant difference in how black and white Zimbabweans relate to the land. Traditionally for the black Zimbabwean land belongs to the ancestors and through the lineage group is allocated by the village head/chief to a head of household. It is returned to the lineage group for redistribution when the household stops farming the plot of land and/or the head of the household dies. No individual can own a piece of land. For the white Zimbabwean, based upon his/her European ancestry, land is owned with a title deed, demarcated and fenced by an individual; a commodity which can be bought and sold. The black Zimbabwean relates to land as something sacred tied to his/her ancestors, whereas the white Zimbabwean relates to the landscape - nature, the wildlife and the products that he/she can obtain from the land, but which the black Zimbabwean feels must be returned to

his/her ancestors (Wels, 2000). The liberation war of Zimbabwe or “Chimurenga” was fought over rectifying the brutal injustices with regards to land and the liberation fighters were known as *Vana Vevhu* or “children of the soil” (Lan, 1990; Murombedzi, 2003 *In:* Adams & Mulligan, 2003).

One way of protesting the loss of land is by hunting, which is deemed “poaching” by whites, landowners and Government. The black African traditionally hunted to live as a form of subsistence. Hunting by black Africans continued for subsistence, cultural and religious purposes, but also as a means of protesting against the confiscation of their land by private individuals and by Government. Breaking the law by poaching created a distorted Western media image of traditional hunters destroying their and humankind’s heritage – wildlife. The struggle about land can be described as a “war over fences” in which the black African is stereotyped as a potential poacher and every white man is a land robber. It has led to a fundamental distrust between black and white in southern Africa when it concerns land and hunting (Wels, 2000)! The politics of the issue center on broad support for an end to the existence of what are essentially white pockets of prosperity surrounded by black poverty (Carney & DeGeorges, 2000). It is thus no wonder that during the Zimbabwe land invasions, one of the first things that happened was the elimination of wildlife by the invaders – a form of eco-retribution!

The fence signifies the general paradox and dilemma of a white wildlife utilization scheme in southern Africa. The fence is necessary to make economic profit through sport hunting, and to make wildlife utilization economically viable. Thus, without a fence, there would be no attractive hunting packages, profit, sustainable business, conservancies, or community investments. At the same time, the fence blocks community relations because it symbolizes the type of domination, which black Africans have protested about and fought against ever

since the advance of the whites in southern Africa: the latter's domination of the land (Wels, 2000).

Lancaster House Agreement, a Hindrance to Radical Land Reform

The Lancaster House Agreement of 1979, which was signed between Great Britain and Zimbabwe at independence made a radical approach towards land redistribution impossible. This new constitution, negotiated with the British, saw to it that designated national parks boundaries were maintained. The constitution only recognized farmland that had boundaries demarcated by beacons, placed by the Surveyor General's Office, and written title deeds. African-owned land based on oral tradition, without such qualities, was not recognized. The Lancaster House Agreement was valid until 1990. It hindered radical land reform because: 1) Government purchased land must be acquired on a willing buyer, willing seller basis, and 2) Government must compensate owners of the purchased land in foreign currency. This solidified the economic strength of the white commercial farmers through freehold land tenure (Wels, 2000; Meredith, 2002).

Attempts to convert rural villages into trust companies, which could manage commercially viable plots of agricultural land, were stopped by President Mugabe, even after adoption by all 55-district councils. Mugabe feared anything that allowed rural communities an effective degree of autonomy, particularly financial, as this might reduce his ability to play patronage politics (Meredith, 2002).

The Beginning of Land Reform

By 1990, the black elite, [e.g., ministers, MPs (Members of Parliament), senior civil servants, police and defense officials, etc.] had acquired 8% of commercial farmland, though little was put into production (Meredith, 2002). This takeover of land by the black elite significantly increased in the 1990s and appears to be part of the agenda for Zimbabwean land reform in the 21st century.

Even though land reform from the early 1980s to the mid-1990s did not take place to the advantage of the rural poor, legislation was in place that completely reformed the constitutional constraints under the Lancaster House Agreement. The Land Acquisition Act of 1992 was enacted to speed up the land reform process, empowering the president and other authorities to compulsorily acquire land: 1) paying in local currency, 2) acquiring fully utilized land and 3) not requiring a willing seller-willing buyer principle.

The State already possessed vast quantities of land, once owned by white farmers, which it did not have the capacity to redistribute. As noted above, resettlement on the best land was delegitimised by cronyism, nepotism and corruption. The government controlled 80% of the land in Zimbabwe including 55% of the most productive farmland and had yet to use productively the majority of the 4 million ha purchased from commercial farmers since 1980 using foreign funds donated for this purpose (Ngwenya, 2001 *In:* Bond & Manyanya, 2003). Of this land in 1997, 12.8% was in protected areas climbing to 14.2% by 2004 (UNEP-WCMC, 2004).

Opposition by white landowners increased throughout the period of 1992-1997. This resulted in Britain withdrawing aid to the land reform program, as it had accused President Mugabe of giving purchased land to his “cronies” (New

African, 2000; Godwin, 2003). Whitehall now claims to have contributed ≈US\$ 70.4 million (£44 million), but Timothy Stamp, Zimbabwe's former (white) finance minister claims it was actually ≈US\$ 27.2 million (£17 million) (New African, 2000). It is claimed that land reform at independence in Kenya was similar. While the Government bought some land from departing Britons and divided it among Kenyan farmers, most of the farms were bought by wealthy Kenyans and politicians (Rosenblum & Williamson, 1987). Parker (2007a) disputes this explaining that

“While some (a few) white owned farms went to black politicians, by far the greater majority did go to small-holders. The country has over 4 million title deed holders and the buy out of white farms is far more a story of considerable success than failure”.

In November 1997, President Mugabe, due to campaign promises, designated up to 5 million ha (13.7 million acres) of farmlands for the resettlement of 100,000 families (The Chronicle, 1997), which amounted to 1,503 white owned farms.⁷⁰ This was estimated to be 45% of the total land held by Zimbabwe's “white” commercial farmers (Meredith, 2002). Initial estimates by the Commercial Farmers Union were that farm worker employment would drop from 327,000 to 180,000 on large scale commercial farms, if the earmarked farms were taken out of commercial production (The Herald, 1997). The majority of these farms were highly productive growing huge hectarages of wheat and maize, as well as high value foreign currency crops such as tobacco (Buckle, 2001). In fact, Zimbabwe's commercial farmers, if allowed to produce, could have fed Zimbabwe and many of the millions of people risking starvation in Angola, Lesotho, Malawi, Mozambique and Swaziland, due to regional conflicts and the drought. What was at risk was one of the “bread baskets” of southern Africa to feed the region, and

⁷⁰ GOZ (1997). This was published as a supplement in the local Zimbabwean newspapers on November 28, 1997 in “General Notice, LAND ACQUISITION ACT (Chapter 20:10), Preliminary Notice to Compulsorily Acquire Land”.

foreign exchange to drive the Zimbabwean economy. Landowners were given 30 days (as the 1992 Act demanded) to submit written objections (New African, 2000).

By September 1998, the Government called a donors conference in Harare on land reform (LRRP II); 48 countries and international organizations attended. The donors unanimously endorsed the land program, saying it was essential for poverty reduction, political stability and economic growth (New African, 2000). Twelve international donors agreed to help fund the purchase of 118 farms of 283,401 ha (700,000 acres) on a willing seller basis by white farmers, with a Technical Support Unit to assure transparency in the implementation of the program over a two-year period to assure that the land went to the poorest of the poor. Nothing happened and then in November 1998, President Mugabe announced the seizure of 841 white-owned farms (Meredith, 2002).

In 1999, the Commercial Farmers Union freely offered for sale to the Government 1.5 million ha for redistribution. As frustration set in on both sides, the Government drafted a new constitution with a clause to compulsorily acquire land for redistribution without paying compensation. The drafting stage of the constitution was largely boycotted by the opposition (supported by the landowners), claiming that Mugabe only wanted a new constitution to entrench himself politically (New African, 2000).

By the beginning of 2000, after 20 years of land reform, only 75,000 black families had been resettled on 3.6 million ha (9 million acres) of land, while whites, making up 1% of the population still owned 28% of all land and 60% of the best farmland on which crops were raised that accounted for 60% of Zimbabwe's exports. Meanwhile, since the early 1980s the black population had

increased by 60% (Godwin, 2003) to about 12 million compounding the problem of land compression, degradation and hence land hunger.

Radicalization of Land Reform

By February 2000, the Government organized a referendum on the new constitution. The country's powerful landed gentry (mostly white, who also controlled the economy) threw its weight and money behind the disparate opposition and human rights groups who formed a united front to fight against the new constitution. Calling themselves the Movement for Democratic Change (MDC), the united front won 55% of the votes as against the ruling Zimbabwe African National Union – Patriotic Front (ZANU-PF)'s 45% (New African, 2000) defeating the referendum; while gaining 57 to ZANU-PF's 62 seats plus 32 seats appointed by the executive in the June 2000 parliamentary elections (Human Rights Watch, 2002). The MDC had promised to purchase for resettlement six to seven million ha of underutilized, derelict and multiple owned land, land already identified and designated for the purpose and corruptly acquired land (Human Rights Watch, 2002). Two weeks after the February 2000 referendum, the land invasions began as the pro-Mugabe War Veterans Association organized people of like mind (not necessary war veterans as many of them were too young to have fought in the Liberation War) to march on white-owned farmlands (New African, 2000). Robert Mugabe excluded whites and their farm workers, mostly of Mozambican and Malawian extraction, from any legitimate place in the landscape (Beinart & McGregor, 2003). However, Sachikonye (2003) dispels this myth. He argues that until the 1960s, the bulk of farm workers were migrants imported from the neighboring countries of Mozambique, Malawi and Zambia since indigenous Zimbabweans shunned farm labor due to poor wages and working conditions. However, by 2000, indigenous Zimbabweans constituted about 75% of the labor force whilst migrants and their descendants made up the remainder. He estimates

a displacement of 200,000 out of 320,000 farm workers and their families totaling 1.8 to 2 million people, with less than 5% being granted land.

Since the land-expropriation campaign started in 2000, the government has seized more than 11 million ha of white-owned land (Thornycroft, 2004a). By 2003, only 200 of the 4,500 white-owned farms remained fully functional (Godwin, 2003). Under the fast track land reform program, model A1 is for 160,000 beneficiaries among the poor to decongest communal areas, with 20% of the resettlement plots reserved for war veterans, while model A2 makes land available with the goal of creating 51,000 small- to medium-scale black indigenous commercial farmers (Human Rights Watch, 2002). By mid-2003, 4.2 million ha (33 ha/household) had been allocated to 127,192 households under the A1 scheme and 1,672 farms totaling 2.1 million ha (276 ha/applicant) had been allocated to 7,620 applicants under the A2 scheme (IRIN, 2004). By 2007, the government estimated redistribution of land to over 150,000 A1 farmers and to 14,000 A2 farmers (All Africa, 2007). Due to a lack of expertise, capital and the cost of inputs, many of the A2 farms lay idle (IRIN, 2004). An estimated 90% of the 300,000 Zimbabweans who were given land by the government under the current land reform program still lacked farm inputs and some 94% did not have seeds for the upcoming season (Clover, 2003). The situation was further aggravated by the uncertainty of tenure, as it appeared that the government still owned the land, making it difficult for farmers to access credit from financial institutions (Roman, 2003). By the end of 2002, Zimbabwe's average farming output was down by about 75% from the previous year (Roman, 2003).

In June 2004, Zimbabwe announced that land would no longer be privately owned, while 99 year leases would be given out to land occupiers (Thornycroft, 2004a). Security of tenure is an issue affecting investment and production (IRIN, 2004) with only 546 out of a target of 8,000 A2 farmers being given 99 year

leases, while A1 resettled farmers will be given permits (All Africa, 2007) to “provide better security to new settlers and instill a sense of ownership and commitment to the land and natural resources” (MET, 2004). Much of the best land has ended in the hands of ZANU-PF leaders and Government officials, military officers and many leading judges (Human Rights Watch, 2002; Thornycroft, 2004a). Godwin (2003) saw tenure as a similar issue, believing many of the title deeds to have been retained by commercial farmers. This has resulted in many farmers reverting to subsistence practices (Godwin, 2003). In 2006, Zimbabwe still cannot afford to import inputs, especially nitrogen fertilizer, while 90% of the land taken from white farmers 6 years ago lay fallow, the new farmers lacking technical support and finances (Thornycroft, 2006a). By the 2006/07 season the total area under maize was 1.2 million ha, or 200,000 ha less than the previous season. This is due to drought and extensive crop failure in the south of the country, and less planted on A2 farms (averaging 80-200 ha/farm). Many A2 farms, with the most productive soils in the country, remain in fallow since “farmers” lack experience, an unwillingness to invest in agriculture under conditions of hyperinflation, costs of inputs (fertilizers and diesel), limited machinery, and experienced farm managers leaving for higher wages in other sectors (USDA, 2007). The devastating toll of HIV/AIDS, with 25% of the population ages 15-49 infected by 2003 (Goliber, 2004) is placing additional burdens on those available to continue with food production feeding those who are incapable of working, with the risk of developing a skewed population of young and old with few available workers.

Impacts of Land Reform on Wildlife and the Environment

While the Zimbabwean Government purports to support wildlife as a land use especially in Regions IV and V (MET, 2004), the reality on the ground indicates otherwise. Key wildlife habitat, forests, are being destroyed at an estimated

400,000 ha/year as people turn to wood for cooking throughout the country due to major power outages (Thornycroft, 2007a). The net result of the politicization of land reform in Zimbabwe has meant destruction of a model conservation program in which hunting grossed US\$ 22.3 million/year at its peak in 1998 (Khumalo, 2005) and ecotourism about US\$ 30 million/year (African Advisory Board, 2000). Originally, an estimated US\$ 15.9 million had gone to rural impoverished communities over an 11 year period of which an average of about 90% was derived from trophy hunting. However, this amounted to only about 7-10% of the annual gross turnover of which 49.7% went to communities or an average gross of US\$ 18.60/household/year for about 95,000 households. Because of the small amount per household, most community income was used for common property benefits (e.g., wells, schools, clinics). Some question whether limited benefits from such a narrowly focused use of resources can justify the maintenance of these vast natural areas without moving to a multiple resource use model. At the same time, conservation must fit into a bigger plan for the urbanization and industrialization of Zimbabwe and the subcontinent, if such land uses are to survive the first half of the 21st century. In addition to habitat degradation from farm invasions, a conservative estimate is a 50% loss in wildlife numbers, a 65% loss of tourism, and a loss of up to 90% of safari hunting on commercial farms (Herbst, 2002; Zimbabwe Independent, 2002) from poaching and habitat destruction. Unti (2007) estimates by 2007, an 80% decline in wildlife in conservancies and game ranches, and 60% in national parks. Zorn (2006) estimates no more than 20 of the 100+ game ranch operations remain. This is believed to be an error in the publication; “200 of 1,000+ game ranch operations remain” being correct. Heath (2006) estimates over 1,000 game ranches prior to the radical land reform, in 2006 reduced to about four functional conservancies of 120 properties, many invaded, plus an additional 60 game ranches scattered around the country. A 2005 constitutional amendment reverted ownership of all white-owned land to the State, but the State lacking the power of eviction without

lengthy court battles. In late 2006, a law was passed giving farmers 90 days to depart once given an eviction notice by the Mugabe Government, but without recourse to the courts (Thornycroft, 2006b). In April 2007, another 226 farmers were given eviction notices (All Africa, 2007) a portion of which would have been game ranches, leaving about 100 functional white farmers in the country – 98% of the white commercial farmers gone (Heath, 2007).

Linked to radical land reform, a collapse of food production and destruction of a once vibrant economy, is what appears to be sanctioned Government poaching in national parks. Although culling elephant in Zimbabwe's national parks as a means of habitat management is not new, Mugabe's ability to stay in power by assuring that his rural constituency is fed has resulted in "Operation Nyama (Meat)" resulting in elephant and other game being shot in national parks and along their borders to feed starving villagers, some accusing this as a front for illegal ivory poaching (Unti, 2007) to China in exchange for weapons. This is indicative of China's rapacious scramble for Africa's natural resources such as oil, minerals and timber. In the first half of 2006, 30 tons of ivory from Zimbabwe's Department of National Parks and Wildlife Management (DNPWM), representing tusks from 2,250 elephants were sold to China, some accusing Zimbabwe of mixing illegal with legally stockpiled ivory (Johnson, 2006) that amounts to 24,000 kg (Unti, 2007). This occurs through non-commercial trade under Convention on International Trade in Endangered Species (CITES) definition, in this case considered export of five items or less of a value of US\$ 500 or less. CITES export permits are issued by the Zimbabwean authorities for each shipment but are not recorded as commercial trade (Johnson, 2006) (see Chapter 10, Section 10.4.6.4, Zimbabwe). CITES, normally very vocal is quiet on this issue. In 2000, Zimbabwe had the world's largest single herd of CITES Appendix I black rhino, numbering about 500, but which was reduced to 200 from poaching by 2004 (Unti, 2007) and a further 80 from poaching in the first

three months of 2007 (VOA, 2007). In addition, trophy hunting is allegedly being allowed to take place within the world renowned Hwange and other national parks (Hammer, 2006). Ironically, Zimbabwe has just been elected to head the United Nation's Commission on Sustainable Development (CSD) that will be chaired by Zimbabwe's Environment Minister Francis Nhema (BBC, 2007a).

Land Reform and Food Shortages

Prior to 2000, extracting data from the USDA (2000), including the El Niño years of 1991 and 1994, total grain harvests of maize and wheat averaged 1.9 million tons/yr of which about 1.7 million tons/year was maize. WRI (2003) estimated total cereal production (maize, wheat, sorghum and millet) averaged 2.2 million tons (1,221 kg/ha/yr) from 1998 to 2001, a 4% decline from the 1979-81 seasons.

By 2002, Zimbabwe faced a severe food shortage projected for 6 million of its 13 million people caused by the farm disruptions coupled with drought. Stocks of maize meal, the staple diet of its 13 million people, had already run out (ZIC, 2002). By 2002, commercial wheat production was down 52% from the year before and the commercial cattle herd fell from 1.3 million head in 1999 to 200,000 by 2002 (Godwin, 2003). In December 2003, the World Food Program (WFP) was forced to cut food aid to 2.6 million Zimbabweans after donors came up with less than half (US\$ 161.3 million) of the US\$ 311 million requested funds to feed 6 million people in southern Africa through June 2004. Of the total amount of food aid, 67% was meant for more than 4 million Zimbabweans who would need assistance by January 2004 when the “lean season”⁷¹ begins with traditional grain shortages among rural households. People did not have the energy to cultivate crops for 2004, and few had the income to purchase staple

⁷¹ In the Sahel of Francophone Africa, this hungry season is called *soudure* beginning around June and ending sometime in the fall (e.g. October/November) at the next harvest (Rosenblum & Williamson, 1987).

food, with prices jumping 50% in the last weeks of December 2003 (Washington Times, 2003). Due to drought conditions and Zimbabwe's deteriorated economic situation, in 2005/06 "10 million people in the region needed food aid – 4 million in Zimbabwe, 4 million in Malawi, 1 million in Zambia, 500,000 in Lesotho, 400,000 in Mozambique, and 200,000 in Swaziland" (Rusere, 2005).

The 2006 season produced the worst ever yield of 700,000 tons of maize - Zimbabwe's staple crop - less than half the amount needed to feed the nation, despite more than adequate rains (Sithole, 2006; Thornycroft, 2006a), while 2007 has been declared a drought year with estimated harvests of 600,000 tons, 25% of the annual national requirement of 2.4 million tons (IRIN, 2007a; USDA, 2007). Extracting information from USDA (2007), maize yields since 2002 are at an all time low, about equal to those of the El Niño years of 1991 and 1994 at around 500-700 kg/ha/year compared to pre-land reform yields of 1,100-1,700 kg/ha/year. FAOSTAT (2007) data indicates an average maize production/yield of 1.7 million tons/1,290 kg/ha/yr from 1990-2000 versus 720,000 tons/543 kg/ha/yr from 2002-2005. The average yield for 2007 will be around 500 kg/ha below the average for the last five years. By the peak hungry (dry) season of December 2006 and January 2007, maize, sorghum and millet stocks for many rural households had run out, while the availability of maize meal in the market became erratic or beyond the purchasing power of the average family due to inflation. Although full statistics were not yet available, as of January 2007 it was determined that the 2006 winter wheat harvest was unlikely to surpass 135,000 tons, a 265,000 shortfall of the 400,000 ton demand until the next harvest (USAID, 2007). FAOSTAT (2007) data indicates average wheat production/yield of 243,000 tons/4,235 kg/ha/yr from 1990-2000 versus 161,000 tons/3,942 kg/ha/yr from 2002-2005. In 2007/08, only 8,000 ha of the projected 76,000 ha had been planted in wheat ahead of the May 31st deadline needed to assure a harvest (The Herald, 2007). Continuing into 2007, last year was the 6th year in a

row of failed crops in Zimbabwe in which 3 million people, 25% of Zimbabwe's population depended on UN food aid (Thornycroft, 2006a). Unfortunately, food aid has been used as a political tool, going preferentially to Mugabe's ZANU-PF supporters. A 2005 letter from a former Zimbabwean student at Tshwane University of Technology living in Chiredzi, southeastern Zimbabwe and a former school teacher summed up Zimbabwe's dilemma in just a few words, "we're starving to death" (Steyn, *pers comm.*).⁷²

In addition to Mugabe's policies helping to create famine by destroying one of the breadbaskets of southern Africa, his 2005 urban campaign, officially named Operation *Murambatsvina* that translates into "clean out the filth", in the majority Shona language is propagating famine. It has displaced 700,000 people from their homes and businesses in urban slums to rural areas (Thornycroft, 2005), where many of the people have neither the know-how nor the implements to farm and is not considering that the region is facing a major drought cycle. There is strong possibility that this incident will be referred to the International Criminal Court (ICC) in The Hague (BBC, 2007b).

Impacts of Land Reform on the Economy

The announcement of this nationalization of farms sent the economy into a tailspin from which it never recovered. The Zimbabwe dollar went from ZD\$ 10/US\$ officially in the mid-1990s to about ZD\$ 6,000/US\$ on the black market by November 2003. "Widespread food insecurity, massive unemployment and economic decline fuel the country's instability. Inflation reached a record high of 135% in the summer of 2002. Three-quarters (75%) of Zimbabweans are living in poverty, and up to half of the population was reported likely to need emergency

⁷² Simon Steyn, former school teacher from Chiredzi Communal area, and former Project Noah scholarship student, Dept. of Nature Conservation, Tshwane University of Technology (TUT).

food aid in 2002/03" (Africa Action, 2003). On August 2, 2005, the Zimbabwe dollar fell to an all time low against the U.S. dollar at ZD\$ 45,000/US\$ (Mutomba, 2005) on the parallel market and by the end of August to around ZD\$ 24,000/US\$ on the official market (Brown & Muleya, 2005). By early 2006 this amounted to ZD\$ 80,000/US\$ on the black market and 26,000/US\$ on the official market (Zorn, 2006). According to the BBC (2007c), in March 2007 the Central Bank's official exchange rate was ZD\$ 250/US\$, and ZD\$ 15,000 for some exporters, international organizations, gold miners, tobacco farmers and remittances from expatriates, while on the black market the rate was ZD\$ 25,000/US\$. Meanwhile inflation had soared to 2,200% by March 2007 (BBC, 2007; Zim Observer, 2007) amounting to an increase in prices of 50.5% (Zulu, 2007), 3,714% by April with prices increasing by 100.7% since March (Zulu, 2007). The IMF projects inflation could climb as high as 5,000% (Thornycroft, 2007b) and Zimbabwe's Labor and Economic Development Research Institute predicts inflation to 10,000% by early 2008 (Zulu, 2007). Hyperinflation is defined as growth in inflation of over 50% month on month (Thornycroft, 2007b). Interest rates on loans were at 500% (Zim Observer, 2007). By December 2006 a loaf of bread cost ZD\$ 800 (USAID, 2007), in reality ZD\$ 800,000 as the government issued new notes in August 2006, slashing three zeros off the currency (Thornycroft, 2006c) and "well beyond the reach of poor households for whom bread traditionally constituted a significant part of their diet" USAID (2007). In May 2007, a small bag of essential goods from the supermarket cost nearly one million Zimbabwe dollars, or US\$ 33 on the black market, and US\$ 4,000 at the official rate of exchange (Thornycroft, 2007b). Making it virtually unaffordable to the average consumer, by May 2007, the official retail price of a 5 kg bag of maize meal soared from ZD\$ 3,200 (US\$ 0.12) to ZD\$ 21,874 (US\$ 0.87), an increase of 583% due to the monopolized Grain Marketing Board increasing payments to farmers as a means of stimulating maize production to achieve national food security. For a family of six with a monthly salary of

between ZD\$ 200,000 (US\$ 8) and ZD\$ 500,000 (US\$ 20), a 20 kg bag of maize meal/month will now cost ZD\$ 78,988.57 (US\$ 3.15), or 16-39% of their salary instead of the previous cost of ZD\$ 11,800 (US\$ 0.47), or 2-6% of their salary (IRIN, 2007a). For the 80% unemployed (IRIN, 2007b; U.K., 2007) this implies malnourishment and living off the land to survive, including the country's wildlife (Unti, 2007).

In addition, Zimbabwe will produce only 50 million kg of tobacco in 2006, where 6 years ago it produced nearly 5 times that amount, earning 40% of the total foreign exchange (Thornycroft, 2006a), at that time the second largest tobacco producer in the world after Brazil (Machipisa, 2000).

Ultimately, Zimbabwe's politicization of land reform failed to address the needs of both the rural and urban poor majority, simply replacing a tiny white elite with an equally small black one.

Impact of Land Reform on Regional Economies

This has had major impacts on regional economies, especially South Africa's. While the G8 committed US\$ 6 billion to development assistance in Africa, South Africa alone lost US \$7.7 billion because of Zimbabwe's economic breakdown (ZIMNEWS, 2002) between the beginning of radical land reform and 2002. Between 2000 and 2003, Zimbabwe's crisis cost the region about US\$ 2.5 billion in investments, and shaved around 1.3% off South Africa's Gross Domestic Product (IRIN, 2006). By the end of 2002, an estimated US\$ 8.9 million was owed to Telkom, South Africa's telecommunications utility; US\$ 11.9 million to ESKOM, the state electricity supplier; US\$ 11.2 million to the Reserve Bank; \$8.2 million to Transnet, the state-run transport company; more than US\$ 11.2

million to the fuel sector, and about US\$ 17.9 million to other companies (IRIN, 2006).

While 500 to 1,000 illegal Zimbabwean immigrants are arrested per week trying to cross the 272 km border, another 10,000/week successfully make it into South Africa (Chibaya, 2006). An estimated 2.5 – 3 million Zimbabweans are living in South Africa, the majority unskilled migrants willing to work for US\$ 5/day or less, negatively impacting the job market for South Africans. Even Zimbabwean professionals such as teachers are employed for as little as US\$ 90/month below the stipulated minimum of US\$ 300/month. Many professionals, who do not find jobs, beg or work as unskilled laborers such as waiters (IRIN, 2006) or security guards. This is putting pressure on South Africa's 27% (official) to 40% (outside analysts) unemployment, adding to the xenophobia that accuses migrants of increasing crime, stealing local jobs, houses, women and children's places in schools (IRIN, 2006) and placing further strain on South Africa's overburdened infrastructure. In neighboring Botswana, daily an estimated 1,000 Zimbabweans cross the border post of Ramokgwebana, the majority looking for work (IRIN, 2007b), with the likelihood that those crossing illegally are many times greater in number.

Conclusions

At the July 2004 summit of the African Union in Addis Ababa, a report was circulated on Zimbabwe produced by the African Union's Commission on Human and Peoples Rights. "It described Zimbabwe as a deeply-divided society, suffering from police abuses, a compromised judicial system, and a stifled media...the report confirmed what many Zimbabwean rights activists had long said, that the abuses had nothing to do with race or land reform or black empowerment" (Thornycroft, 2004b). This implies that what has happened is

linked to a struggle between various factions for political power. Unfortunately, the AU has put off dealing with this issue for at least another year (Majtenyi, 2004b).

The reality of the matter is that regardless of whether land reform is undertaken properly or not, care must be taken that within one generation these farms do not become subdivided into uneconomical units that result in further mining of the soils, as is occurring across the Continent, resulting in renewed land hunger. This will require establishing legal limits on minimal farm sizes to assure economically viable units. Some claim that such limits on minimal farm size exist based upon the productivity in the agro-ecological zones. They also claim that the “master farmer training program” in existence since the Ian Smith era and “farmer field schools” (Heinrich, 2004; CGIAR. 2006) can continue to provide a nucleus of small-scale commercial farmers who can bring back Zimbabwe’s food production if given credit to purchase inputs. One can only hope that this comes to fruition. It also implies that if ecological/economic minimal land sizes per farm are respected, the ratio of the available number of farms, to population that grew 4.3x from 2.9 to 12.2 million between 1950 and 2000 (USBC, 2004) and is expected to increase to 14.6 million in 50 years (Goliber, 2004), is likely to be so small that the future for the majority of sons and daughters of today’s small and medium farmers in Zimbabwe will be in off-farm pursuits.

Furthermore, the current climate created in Zimbabwe has negated that country’s contribution to the global conservation effort with the immediate extinction of wildlife a reality and that followed by an ecological disaster as millions of people scratch a living off the land. What has happened in Zimbabwe should be a wake-up call to Southern Africans, especially South Africa. While the authors recognize the injustices of colonialism, two wrongs do not make a right. If land reform in Namibia and South Africa take similar paths, not only could it mean an

ecological catastrophe, but destruction of the agro-industrial complex critical to fueling the subcontinent's economic engine, South Africa. South Africa is the "life raft" that can help save the rest of the subcontinent. However, poorly thought out internal and regional policies that result in economic ruin and uncontrollable immigration by the poor, hopeless disenfranchised masses could end any hope for an "African Renaissance", and end any hope for Africa's people to benefit from the technological solutions to development that this country may offer.

5.7.4.2 Land reform and South Africa

Zimbabwe's next door neighbor, South Africa has similar land inequities (see Section 5.6.1.7, Impacts of colonialism on traditional agriculture in South Africa). However, South Africa appears to be undertaking land reform in a methodical manner in order to avoid disrupting the economy and food production (Magome & Murombedzi, 2003 *In:* Adams & Mulligan, 2003). So far the South African government has stayed firmly within the constitutional framework on land issues, thereby respecting property rights. By December 2004, about 70% of some 80,000 land restitution claims had been quietly settled and 812,315 ha of land had been transferred amounting to less than 1% of the commercial land. There are 9,000 rural claims involving millions of people that are still outstanding. "By December 2004, total land delivered under land reform amounted to 3.5 million ha (i.e., land delivered under the redistribution, restitution and tenure reform programs, and including state land)" (Bernstein, 2005). Land claims had been reduced down to 7,000 by early 2006 (Sapa-AFP, 2006).

It is important to note that South Africa is the last country in Africa that can feed itself and in normal years provides a surplus to feed much of Southern Africa. With Zimbabwe, the other surplus food producer out of action, it becomes critical

that land reform take into account the need to maintain current levels of commercial agricultural production. Many would argue that land reform is too slow and that there is not an adequate plan to train black South Africans in commercial farming to the point that they can run these farms on their own. Such a plan would assure that properly trained individuals/groups are given these commercial farms to run as opposed to non-farmers. South Africa's original goal of redistributing 30% of the white-owned land to landless blacks by 1999 has not been achieved, with estimations running from less than 5% (Godwin, 2003) to less than 2% (Bond, 2002) having been redistributed, and the target date having been moved to 2015 (Godwin, 2003). In early 2006, it was announced that "willing seller willing buyer" would no longer apply to land restitution cases. The government is willing to pay, but not at what it considers inflated prices (Sapa-AFP, 2006). The draft AgriBEE (2004) released in July 2004 sets goals of:

- 30% of agricultural land owned by black South Africans by 2014;
- 20% of high potential/unique agricultural land for lease by black South Africans by 2014;
- 15% of high potential/unique agricultural land for acquisition by 2010; and
- 10% of agricultural land available to farm workers for animals and plant production.

Achieving this target will not be easy. By December 2004 only 4.3% of commercial agricultural land (3.5 million ha mentioned above) had been transferred to blacks; 3.4% discounting transferred state land (Bernstein, 2005). In July 2005 "at a national land summit in Johannesburg, Deputy President Phumzile Mlambo-Ngcuka said the current market-based approach was not working", where the whites, making up 10% of the population, control 80% of the agricultural land (BBC, 2005). South Africa must approach land reform cautiously as the current agro-industrial complex employs hundreds of thousands

of farm and factory workers (see Chapter 12, Section 12.2.4.2, Agricultural subsidies) and South Africa is the last country on the subcontinent that can feed itself. Taking the wrong path could see land handed over to people who are incapable of commercially farming this land, the collapse of a once viable agro-industrial complex that is a net exporter of food, grocery shelves, as on most of the subcontinent, with a sparse variety of goods often of poor quality and urban centers that will be fed by handouts from the West turning South Africa into another puppet state. The protection of the South African farmer from subsidized food emanating from the West will be critical if this important sector is to continue playing an important role nutritionally and economically in the region (see Chapter 12, Section 12.2.4.2, Agricultural subsidies).

The record to date of commercial farms being turned over to rural communities in South Africa has been abysmal, because of a lack of skills, capital, and inadequate extension services (DuToit, 2004). The realization of the goals set out in the Agricultural Black Economic Empowerment (AgriBEE) document needs to be undertaken in a partnership between government and the private sector so as to assure an orderly transition, while maintaining food production for the region (National Department of Agriculture, 2003). Realizing that the key to moving black South Africans into commercial agriculture is education, the following goals have been set, including the introduction of mentoring programs [implying the establishment of relationships between white commercial farmers as mentors to small-scale/small black commercial farmers and aspiring black farmers (e.g., young black university/agricultural college graduates)] (AgriBEE, 2004) (see Section 5.12.6.1, South Africa, an emerging model in public private partnerships):

- 75% literacy rate within farming communities by 2008;
- Complete literacy by 2010 within farming communities;

- All workers in secondary and tertiary sectors of agriculture literate by 2010;
- Training programs for farm and enterprise workers in appropriate technical and management skills by 2005 including use of private sector agro-industries in-house capabilities for training; and
- Young professionals' employment and mentoring program targeting 5,000 unemployed and underemployed graduates/year over the next five years starting in 2005.

According to Bernstein (2005), additional targets set by AgriBEE include:

- 30% representation of black people in executive management by 2006 in the agricultural sector;
- 50% representation of black people in senior management by 2008;
- 60% representation of black people in middle management by 2008;
- 10% representation of black women in executive management by 2006;
- 25% representation of black women in senior management by 2008;
- 30% representation of black women in middle management by 2008;
- 45% representation of black women in junior management by 2008; and
- Source 50% of all procurements from BEE companies by 2010 and 70% by 2014.

While all of this is laudable, one must realize that farming is not all that it is cracked up to be. It is hard work, long hours and very competitive. Due to globalization, elimination of farm subsidies and resulting increases in costs, farming has gone from 23% of the GDP in 1920 to 3.4% in 2002 (Bernstein, 2005) to 4% (OECD, 2006), as the number of white commercial farmers has contracted over the last 15 years from 78,000 to 45,000 (Bernstein, 2005).

However, the value of farming to the overall economy, considering linkages to other sectors such as agro-industry could be as high as 20-30% of the GDP, employing 10% of the work force or 814,000 people (Nieuwoudt & Groenewald, 2003; OECD, 2006) and 33% of total production exported (OECD, 2006). Thus, land reform must be undertaken with great caution so as to maintain the economic viability of the agricultural sector, without which the country could be thrown into an economic tailspin.

Furthermore, the Center For Development Enterprise in South Africa believes that too much emphasis is being placed on rural land reform, while South Africa has evolved into an urban/peri-urban society (60% urbanized by 2005, 70% before 2014) with an increasing need for urban land redistribution where the majority of the populace lives and is in need of basic infrastructure and shelter. It is also recognized that while people have socio-political ties to the land of their ancestors as in Zimbabwe, this does not necessarily equate with the desire to farm (Bernstein, 2005).

There is a general tendency that once a person becomes urbanized, it is rare that they will return to rural areas of their own volition during the productive portion of the lives, other than for short-term interventions such as planting/harvesting, unless out of desperation, “politics of despair” (see Chapter 9, Section 9.6.1.2, Kifluku Farm, Laikipia, Kenya, Section 9.7.8, Lack Of Adequate Alternative Livelihoods, Section 9.7.8.1, Politics of despair, Zambia and Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem” and Section 9.7.8.3, Need for non-rural livelihood alternatives through industrialization). Those children raised in an urban environment will likely never become farmers, nor will they have a desire to farm. “Based upon national surveys, only 9% of black people who are currently not farmers have clear farming aspirations. Other surveys suggest that only about 15% of farm workers have aspirations to farm on

their own, or to farm full-time" (Bernstein, 2005) with rural land being a priority issue for only 2% of those surveyed versus unemployment (57%) and urban land/housing (35%) (Bernstein, 2005).

The private sector is playing an important role in rural transformation. Programs are underway by Cotton SA to increase production and the numbers of the currently 3,000 small-scale farmers (Louw, *pers. comm.*).

"...the sugar industry has created almost 48,000 small (mainly black) farmers over the past three decades. In 2004, the South African Sugar Association set up the Inkezo Land Company, a section 21 company which aims to transfer 78,000 ha of land to emergent growers by 2014...The timber industry has established outgrower arrangements with more than 10,000 emerging producers...South African Breweries has promised some 180 emergent farmers in the Taung area, near Kimberley, that it will buy their crop, thus providing security for the farmers..." (Bernstein, 2005),

while similar initiatives are being undertaken by the Land for Peace Initiative, the Red Meat Producers Organization, the Grain Producers Organization, Boeresake, The Coastal Farmers Cooperative in KwaZulu Natal, MKTV-Tobacco, SOK and Senwes, The Northern Cape Agricultural Union and the North West Agricultural Union, etc. (Bernstein, 2005). Further discussion in transformation is contained in Section 5.12.6.1, South Africa, an emerging model in public private partnerships on mentoring.

It is believed that deracialization of commercial agricultural land "will not benefit primarily poor black South Africans; the benefits will mainly accrue to a small number of relatively better-off black land owners and potential farmers" (Bernstein, 2005). In fact,

“...President Thabo Mbeki are among many South Africans who have become increasingly critical of black empowerment deals over recent years, charging that the same small group of individuals benefit over and over again. They say this has resulted in a small super-rich black elite, and add that the deals rarely benefit the poor” (Robertson, 2005). In South Africa, some call these elite “black diamonds”.

The feeling is that land reform must be brought up to date with much more of an emphasis on urban issues (Bernstein, 2005).

“Rural land reform (alone – See Chapter 9 discussing the concept of resource/population ratios in rural Africa) is not the answer to rural poverty. South Africa’s national development strategy needs to encompass a suite of programs to effectively lift millions of South Africans out of poverty (the majority living in urban areas). The keys here are quality education, employment, urbanization, and a new strategic vision of the role of the rural sector in economic development. South Africa has never had a rural development strategy; it is time we developed and implemented one that is relevant to Africa’s most urbanized and industrial economy...if land issues are not successfully handled, they have the potential to destabilize the country politically, and derail other national development goals and priorities” (Bernstein, 2005).

The announcement by President Mbeki in his State of the Nation address to Parliament indicated the “state would review the ‘willing buyer, willing seller policy’ as well as ‘land acquisition models and possible manipulation of land prices,’ ” the feeling being the current situation is counter productive to achieving the 2014 goal (Sapa-AFP, 2006). The process in which this is implemented could determine the future of food sovereignty, the economy and Foreign Direct Investment (FDI). The future in how land reform is undertaken may also be critical to the future of the hunting and game ranching industry in South Africa. The majority of game ranches are owned by wealthy urbanites who do not depend on these farms for a livelihood, often serving as weekend retreats, and often not operated to make a profit. Even though many of these farms are on land that is

marginal for agriculture, how the land reform process views these areas (e.g., under-utilized), as in Zimbabwe, could have a major impact on the long-term viability of this industry.

In addition, the South Africa's safari industry composed of game ranchers, safari operators and professional hunters is 99% white. Provincial nature conservation authorities have increased the number of black (previously disadvantaged) staff, their biggest challenge being to find qualified personnel, though this should improve over the next decade as more black South Africans have access to a university education. Realizing, the safari industry could be in jeopardy if seen purely as a "white man's game," the Professional Hunters Association of South Africa (PHASA) raised US\$ 98,000 (R680,000) on May 2007 towards bursaries for black students to the South African Wildlife College (SAWC) (ASG, 2007). Though laudable, this would seem to be directing students towards being trained to work in provincial nature conservation authorities as opposed to going to professional hunting schools, the road to becoming a safari operator. If the professional hunting/safari operator and game ranching industry remains lily white, while the only opportunities for blacks are in government, there is a strong risk, game ranching in South Africa could go the way of Zimbabwe; taken over by black communities that convert it to other land uses, as they see little or no value in maintaining natural systems and game. The Professional Hunters Association of South Africa (PHASA) and the game ranching industry must throw their doors open to black South Africans, acting as mentors (see, Namibian professional hunting model, Chapter 9, Section 9.7.5.6, LIFE, Namibia, Nyae Nyae Conservancy.

5.7.4.3 Land reform around the corner in Namibia

Although slow, to date, Namibia has had open dialogue between various stakeholders through the Land Reform Advisory Commission including: 1) white Namibians comprising about 5-8% of the Namibia's population of +/- 2 million, who own about 95% of the farms consisting of 4,000 commercial mostly white ranches 2) 240,000 blacks awaiting resettlement and 3) the government, with land being given over supposedly on a willing buyer, willing seller basis (Shiner, 2004; Thibodeaux, 2005). Today, between 50-80% of Namibia's farmable land belongs to white farmers, while black farmers own about 16%, mostly in over-grazed communal areas (Shiner, 2004; Thibodeaux, 2005). In the early 1900s between 60,000 (Hochschild, 1998) and 80,000 black people lost their lives to German colonization (Shiner, 2004) and the confiscation of their land.

The black Namibian Farmworkers Union has threatened Zimbabwe-like land invasions because of a land reform process being allegedly slowed by commercial farmers. This includes unreasonably high prices being asked for white farms and only the poorer lands being made available for purchase by black farmers/government. Because of this, the Ministry of Lands is embarking on expropriations, bringing about concern of a Zimbabwe-like fast track program (Shiner, 2004). In 2004, Namibia announced an ambitious campaign to acquire land earmarking about US\$ 170 million, less than US\$ 20/ha, well below market value, to buy about 9 million ha of white-owned farms and ranches by 2010. The strategy consists of expropriating white-owned farms, in essence threatening to confiscate farms if their owners refuse to sell at prices set by government assessors. Namibia's land ministry sent out expropriation notices to about 17 white Namibian farmers, most of whom are reported to have had labor disputes with black Namibian farm workers (Thibodeaux, 2005). The predominantly white commercial farmers' Namibian Agricultural Union denies concern

explaining that the delay is about the selling of property that must be based not only on a fair price for the property but the loss of income over a certain period, thus making compensation equal to market value plus a percentage. “The pace of reform is expected to accelerate one way or another after presidential elections this year (2004). Hifikepunye Pohamba, the then Lands Minister and Southwest Africa People’s Organization (SWAPO)’s presidential candidate was expected to (Shiner, 2004) and did win.

In mid-2005, the first white-owned farm of 4,000 ha belonging to the Wiese family was sold to the Namibian government for resettlement. This farm was purchased by the family from the German government in 1903. According to the Wiese family, they were set up in a labor dispute staged by the farm workers to embolden the government to expropriate the farm. After a two-year battle with the lands ministry, they were coerced into the sale of their property for less than 50% of the asking price, US\$ 1.4 million (9 million Namibian dollars) versus US\$ 575,428 (3.7 million Namibian dollars) (SUNTIMES, 2005), after government threatened seizure of the property. Namibia’s “land reform policies, like nearby Zimbabwe's, look better on paper than in practice” (Thibodeaux, 2005).

Well known African ecologist, writer and policy advisor, Ian Parker feels that land reform in Southern Africa is inevitable (Parker, 2007b):

“When one plotted (human) population density against rainfall in all sub-Saharan countries, unsurprisingly, the highest densities were at the higher end of the (annual rainfall) rainfall distribution (except where it exceeded 2,000 mm p.a. (per year) when densities fell sharply - but this affected <3% of the total area). Two exceptions were Zim and SA (South Africa), where there were anomalous upward bulges below the 750 mm p.a. isohyet. They existed due to the segregated racial policies. On purely biological grounds I and Richard Bell predicted that such distributions could only be temporary and that in due course the bulges would redistribute themselves up the rainfall gradients. The biological

forces would undoubtedly be expressed as political policies that could take any of several options, but make no mistake, the inevitability of redistributed densities would be biologically driven. Politics were merely the expression in terms of human behavior. What Bell and I said was that the best option open to white Zimbos (Zimbabweans) given the inevitability of what would happen, was to initiate the process of redistribution themselves while they had the latitude to do so. If they resisted, the consequences for them would be the least pleasant. As I recall, Rowan Martin objected with intellectual elegance. However, history has proved us right in Zim and it will be RSA's turn next!"

One can only hope that land reform in South Africa and Namibia is undertaken in a constructive manner that improves the lives of the people and economies. Zimbabwe is certainly not the model to follow.

5.7.4.4 Land reform and civil war in the Ivory Coast

Although religion and ethnicity may also be playing a role, the current civil war in Ivory Coast is believed largely due to the migration of Muslim Burkinabé from an over-populated and degraded Burkina Faso/Sahel southward into a largely Christian Ivory Coast. "Between a third (33%) and a half (50%) of the country's population is now non-Ivorian, and the figure could be as high as 75% in Abidjan" (Kaplan, 1994). The civil war between the north and the south is as much about natural resources, which is access to the country's rich agricultural land. According to Pavy (*pers. comm.*), the civil war in the Ivory Coast is all about land that is now a scarce resource. As fallow periods decreased and soils began playing themselves out over the past 20-25 years, small-scale farmers began immigrating to the Ivory Coast from Sahelian countries such as Burkina Faso, Senegal and Mali, where human densities may be as high as 90 to 120 persons/ km². Many of the rebel fighters from northern Ivory Coast are traditional Dozo hunters/warriors, as described in Chapter 2, whose history dates back to the 1236 A.D. under the Mandingo Empire of Sundjata (Sundiata) Keita. Likewise,

because of the droughts of 1969-74 and 1980-84, Fulani herders have moved into the Ivory Coast. By cross-breeding with trypano-tolerant cattle (e.g., N'Dama and West African Short-horned [See Chapter 1, Section 1.1.4, Origins of Domestic Livestock and Pastoralism in Africa], through inoculations and skilled movement of their herds to avoid tsetse flies, their herds increased from 38,000 in 1966 to 255,000 by 1984, allowing Ivory Coast to meet 56% of its beef demand (Smith, 1992). Such increases in cattle numbers would also certainly have caused conflict between herders and small-scale farmers?

“One of the main sticking points of the stalled peace deal in Ivory Coast relates to changing nationality laws which would allow more immigrants to become landowners. The question divides both populations in the forested interior of the country and in the southern commercial capital, Abidjan. Over the past several decades, northern migrant farmers turned dense forestland in central and western Ivory Coast into profitable cocoa, coffee and palm oil plantations. But a 1998 law stipulated that only Ivorians can be landowners” (Colombant, 2004b).

Since 2004, village chiefs with the support of government security forces have started taking over land from “foreign farmers”, which they say is rightfully theirs. There never were any formal agreements on the immigrants’ exploitation of forest land and even though foreigners bought the land doesn’t mean that they own it, as usually there are no clear legally binding contracts. “The Ivorian peace deal calls for nationality requirements to be eased, allowing up to 3 million foreigners to become Ivorians - meaning they could also become landowners....Many Ivorians fear the change could spark more instability” (Colombant, 2004b). In some areas, chased out foreigners and immigrants are allowed to return if they start paying rent. This model is now being repeated elsewhere, but if naturalized Ivorians start laying claim to land, it could derail the fragile process. The power-sharing peace accord calls on parliament to swiftly change the nationality law. However, lawmakers from President Laurent Gbagbo’s party have so far managed to prevent it from being passed, fearing it

would mean a loss of economic power for indigenous Ivory Coast farmers (Colombant, 2004b). In October 2005, Ivory Coast's opposition bloc, known as the G7, threatened to withdraw its ministers from the country's unity government if President Laurent Gbagbo's did not step down at the expiration of his elected five-year mandate ending October 26. Gbagbo has the backing of a U.N. Security Council resolution supporting his continuing in office for a maximum of one year (Bavier, 2005). A fragile peace exists from the civil war that broke out five years ago that could go into remittance if the unity government collapses. In March 2007, a peace accord was signed between government and the New Forces rebel army, making former rebel leader Guillaume Soro the prime minister. Though the twice delayed presidential elections may occur by December 2007 (postponed until June/July 2008), there are concerns over issuance of national identity cards and transparency of such elections (Tran, 2007a; 2007b). In August 2007, disarmament of militias and integration of rebel forces into the Ivorian army had yet to take place. In early 2008, progress in ending the 5 year conflict remains stagnant, with a government run south and rebel held north. Periodic attempts at rebel integration and disarmament, as well as issuing identity documents to several million northerners have failed to reach fruition. National elections will likely be put off again.

5.7.5 Food Security and Urbanization in Sub-Saharan Africa

In the future, urbanization will pose the most dramatic challenges to food security. As rural areas become over-populated (see below), and limited opportunities exist to earn a viable living from the land, as more people receive Western education and as modern communications show what else there is besides a hoe, the youth of Africa are flocking out of the rural areas in search of a better life.

This is placing tremendous pressure on the most productive agricultural lands in the countryside, contributing to deforestation and desertification, as well as massive emigration towards major urban centers, producing “urban jungles” in growing “mega-cities”, which are ill-prepared for this onslaught – “the Lomé-Abidjan coastal corridor--indeed, the entire stretch of coast from Abidjan eastward to Lagos--is one burgeoning megalopolis that by any rational economic and geographical standard should constitute a single sovereignty, rather than the five (the Ivory Coast, Ghana, Togo, Benin, and Nigeria) into which it is currently divided” (Kaplan, 1994). Unfortunately, adequate urban infrastructure (water, sewage and housing, etc.), and job opportunities do not yet exist. This poses a major problem for African governments, to feed these urban masses, to find socio-economic solutions to poverty and crime and ultimately to assure political stability.

The proportion of Sub-Saharan Africa’s population living in cities has doubled from 15% in the 1960s to over 30% today and had the highest urbanization rate in the world of 4.3% in 1995 (Ruel, Garrett, Morris, Maxwell, Oshaug, Engle, Menon, Slack & Haddad, 1998 *In:* Swift & Hamilton, 2001 *In:* Devereux & Maxwell, 2001a). This urban migration has created mega-cities such as Lagos, Kinshasa, Brazzaville, Douala, Abidjan, Accra and Dakar in West and Central Africa; Nairobi, Kampala and Addis Ababa in East Africa, and the Pretoria/Johannesburg complex in South Africa. Yet the pull of many secondary cities such as Bouaké, Ibadan, Kaolack and Kumasi is also important. While there are signs that growth rates of 6% (4.3% above) will probably not continue, the trend towards continued swelling of the mega-cities and rising numbers of large secondary cities undoubtedly will. It is projected that that the number of cities in the region with more than 100,000 inhabitants will grow from 90 in 1990 to more than 300 in 2020. Increased urban densities will be the most pronounced, by a wide margin, in Nigeria, which will have more than half of these cities. Lagos

alone will have roughly 12-15 million inhabitants (IFAD, 2001). Some models predict that by 2020 that there will be one continuous coastal city between Lagos and Abidjan (*Pavy, pers. comm.*).

It is estimated that the urban population in Sub-Saharan Africa will overtake the rural population by 2020 with more than 50% living in urban settings. This will require that agricultural production and security strategies look beyond subsistence production in rural areas to supplying cheap, safe food to the cities (Ruel, *et al.*, 1998 *In: Swift & Hamilton, 2001 In: Devereux & Maxwell, 2001a*).

It is estimated that 40% of African urban dwellers farm to some degree (Ruel, *et al.*, 1998 *In: Swift & Hamilton, 2001 In: Devereux & Maxwell, 2001a*).

“Huge slum cities of Africa are growing apace, day by day, unplanned, and in ways which threaten serious social tensions in years to come...On present trends Africa will be, by 2030, an urban continent. Already 166 million people live in slums. Living conditions there are made worse by the lack of access to water, sewage, electricity, refuse collection or other municipal services by local authorities ill-equipped, or unwilling, to address them. In cities like Nairobi 60% of the people live on just 5% of the land. And these slums are filled with an increasingly youthful population, unemployed and disaffected. Africa’s cities are becoming a powder keg of potential instability and discontent” (Commission for Africa, 2005).

Who is going to feed these urban masses? This urbanization process has implications for policies relating to international trade, internal food marketing and subsidy programs (Devereux & Maxwell, 2001a). As the rural poor flee over-populated marginal areas which can no longer assure them a decent quality of life, they leave behind women, children and old people to do the farming, maybe returning for a couple of weeks/year to help cultivate. In Africa, often, too much research and extension is directed towards increasing land productivity (higher yields, improved fallow management) when labor is the real constraint (IFAD, 2001).

Ultimately, as the population in Sub-Saharan Africa, of which 44% is under the age of 15 (Pop. Ref. Bur., 2004), comes into the work force, they will live out their most productive years in economies ill prepared to provide them with opportunities. The effects of over-population, prolonged drought, inappropriate and unsustainable agricultural practices, failing economies, and sub-standard education and health-care systems have major political and social ramifications creating an atmosphere ripe for civil strife, and one of the largest refugee populations in the world. The combination of population, environmental degradation and politics has contributed to civil unrest and bloody conflicts blanketing the continent.

5.7.6 Weakness of Entrepreneurship and the Private Sector, Constraint to Food Production

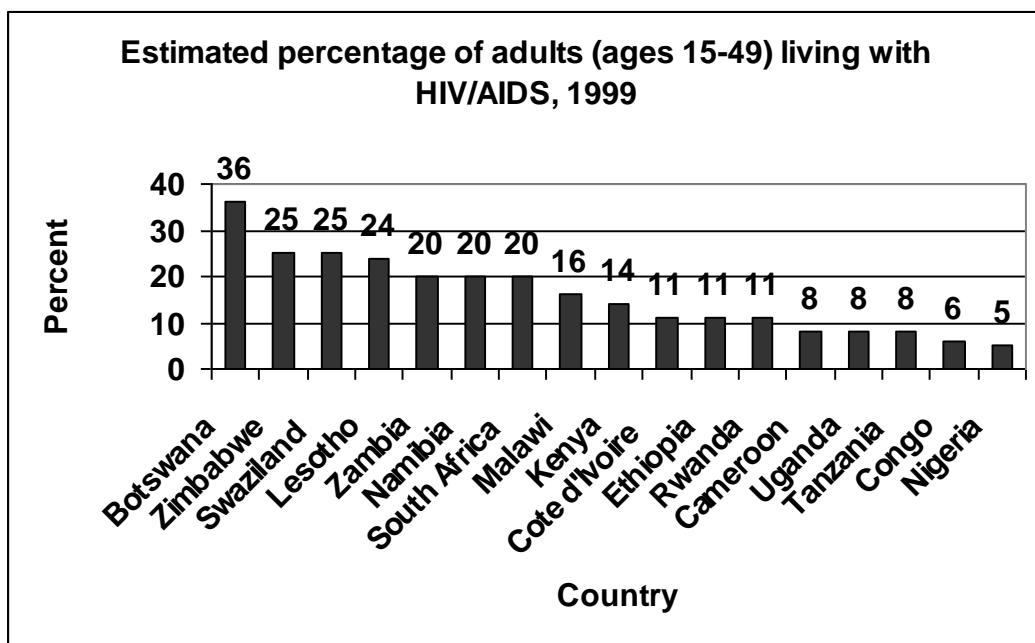

Many African countries have no local private sector to speak of in the agricultural and agro-industry sectors. While it is now fashionable to speak of the African “smallholder” as the region's true private sector, the reality gives cause for great concern. The African smallholder of today may be private but: 1) lacks education, 2) has severely limited access to communications or physical infrastructure, 3) suffers poor health and nutrition, 4) lacks remunerative markets and access to yield-enhancing inputs (e.g., fertilizers and pesticides) and technologies (e.g. genetically modified crops, tractors, latest irrigation technologies), and 5) faces competition with products from abroad that have been subsidized by more money than he/she can ever dream of (NEPAD, 2002).

“This farmer may constitute a ‘private sector’ but cannot stand alongside and compete with multinational farming and agro-industrial giants that trade with Africa. Whether labeled as private sector or otherwise, the smallholder farmer class also often suffers marginalization, with no voice to influence policy and to secure support services that are tailored to his needs. Africa cannot afford to be lured into complacency by references to a large smallholder

private sector. It needs to develop a true rural entrepreneurial capacity. Successful entrepreneurship requires fair prospects for competitive access to markets both at home and internationally and the information to enable the farmer to get the best from such markets, along with overcoming the above constraints" (NEPAD, 2002).

5.8 HIV/AIDS DECLINING AGRICULTURAL PRODUCTION AND FOOD SECURITY IN SUB-SAHARAN AFRICA

Each day 10,000 people are infected with HIV/AIDS in Sub-Saharan Africa, turning this from a health to a development problem integrally linked to the current food crisis (Figure 5.8) (IFPRI, 2000) (see Chapter 12, Section 12.6.1.1, Increase in poverty and decline in health from structural adjustment).

Note: Highest rates from other regions Haiti (5.2%), Bahamas (4.13%), Thailand (2.2%), USA (0.6%)

Source: IFAD, 2002, with permission, UN & International Fund for Agricultural Development of the United Nations (IFAD).

Figure 5.8: Estimated percentage of adults (15-49 years) living with HIV/AIDS, 1999

In Africa, 6,300 people/day die from HIV/AIDS. Of the 5 million new infections globally in 2003, about 3.2 million came from Africa and of the total of 40 million infected globally 26.6 million lived in Africa in 2003 (ICG, 2004a). It is estimated that of the 36 million people worldwide currently infected with HIV/AIDS, 95% live in the developing world, 70% (25.2 million) in Sub-Saharan Africa (IFPRI, 2000). Sub-Saharan Africa has already lost nearly 14 million to AIDS, and is projected to lose another 23 million by 2020. Similarly, the U.S. Department of Agriculture (USDA) estimated that Sub-Saharan Africa, with 11% of the global population, has an estimated 73% of global HIV/AIDS related infections (Shapouri & Rosen, 2001). It is estimated that nearly one in ten Africans infected with HIV/AIDS will die in 2004, or 2.5 million people, with a doubling of this figure expected by the end of the decade (ICG, 2004a).

The latest figures for HIV/AIDS in Africa are given in Table 5.11. The apparent declines do not indicate a decline in HIV/AIDS in Africa but in how the statistics were derived. HIV/AIDS is still on the rise in Africa (ICG, 2004a).

Table 5.11: HIV/AIDS infections in Africa (millions of people)

Figures for Africa in:	2002	2003
New Infections	3.5 million	3.2 million
Living with AIDS	29.4 million	26.6 million
Died of AIDS	2.4 million	2.3 million

Source: UNAIDS (2003) *In:* ICG (2004a), with permission International Crisis Group (ICG) & public domain.

“Food production, already lagging behind population growth in most countries in Sub-Saharan Africa, is now falling fast as the number of field workers shrinks. As food production falls, hunger intensifies among the dependent groups of children and elderly. Malnutrition weakens the immune systems of some, the virus weakens the immune systems of others, and some have immune

systems weakened by both. The downward spiral in family welfare typically begins when the first adult falls victim to the illness—a development that is doubly disruptive because for each person who is sick and unable to work, others must devote at least part of their time caring for that family member” (Brown, 2003a).

Households caring for an AIDS patient turn to a number of different coping strategies, most of which lead to less income and less food security. AIDS decreases income and agricultural production by removing from the labor force not only the sick person, but also other members of the household who must care for the patient (IFPRI, 2000; Roman, 2003).

Women, the mainstay in much of traditional Africa’s food production and food security at the household level are among the hardest hit with AIDS. It is estimated that women produce from 70% (Commission for Africa, 2005) to 80% of the staple food in Sub-Saharan Africa (Madeley, 2002) plus

“half of the animal husbandry in addition to food preparation, gathering firewood, fetching water, childcare and the care of the sick and the elderly. Women spend most of the earnings they control on household needs, particularly for the children, whilst men spend a significantly higher amount on themselves” (Commission for Africa, 2005).

Alemayehu (2000) estimates in Sub-Saharan Africa women contribute 60-80% of the field hands and 50% of the cattle tenders.

An estimated 7 million farmers have died from HIV/AIDS in Africa and these are mostly women, who make up 80% of the agricultural work force (Morris, 2004). Shapouri and Rosen (2001) estimate that 55% of all HIV infections in Sub-Saharan Africa are among women.

“In the 10 most affected African countries, labor force decreases ranging from 10-26% are anticipated. The UN estimated that 9.6% of Zimbabwe’s agricultural labor force was lost in 2000, Malawi losing 5.8%. What we are seeing in Southern Africa is that the food shortages are now exacerbating the downward spiral of health, both of those suffering from HIV/AIDS and children suffering malnourishment” (Roman, 2003).

Grandparents are often burdened with raising and feeding orphans. Food is believed to be the first line of defense against HIV/AIDS, prolonging the lives of infected parents enabling them to raise their children (Morris, 2004). Life expectancies are dropping and nearly 13 million children have been orphaned by the epidemic in Sub-Saharan Africa (IFAD, 2002).

Food insecurity caused by AIDS can extend beyond individual households. When a large enough number of people are ill or have died because of AIDS, food production for an entire region or country could be compromised. For instance in 1999, Ugandan farmers in the region around Kampala traditionally grew *matooke* (green banana) and supplied it to other regions of the country. Because of the loss of labor caused by AIDS related illnesses and deaths, the production of *matooke* has fallen, and this decrease in production has affected not only people growing *matooke* for their own uses, but also the availability of the crop for people in other parts of the country (IFPRI, 2000).

Loss of labor and income can also cause survivors to abandon agricultural practices that raise yields and protect soil fertility, like fallowing and use of fertilizers (IFPRI, 2000). Ultimately, HIV/AIDS means, “an ever smaller number of young adults (many of whom will be living with AIDS) will have to support large numbers of young and old people” (IFAD, 2002).

“The projected population decline from HIV/AIDS, coupled with a reduction in the number of agricultural laborers, will reduce labor productivity by 12%/year for the region (Sub-Saharan Africa).

Because of the decline in labor productivity, grain output fell 3.3% relative to the base-level projections, causing food gaps to grow. The region's food gap to maintain per capita consumption levels jumped 15%, while the nutrition gap rose an estimated 13%" (Shapouri & Rosen, 2001).

5.8.1 Linking HIV/AIDS to the Bushmeat Trade

Some of the most recent research seems to link HIV and the risk of similar viral infections to non-human primates and the bushmeat trade (BCTF, 2003; Wolfe, Switzer, Carr, Bhullar, Shanmugam, Tamoufe, Prosser, Torimiro, Wright, Mpoudi-Ngole, McCutchan, Birx, Folks, Burke & Heneine, 2004). Bushmeat constitutes 80% of all animal-based protein consumed in Central Africa, and represents as much as 50% of the daily protein intake for rural and urban families in that part of Sub-Saharan Africa. In the forest region, as the numbers of duikers decline (most commonly hunted antelope) from over-hunting (mostly by snaring) and habitat degradation, hunters shift to crossbows and poisoned arrows, or more expensive shotguns to harvest primates (BCTF, 2003) (see Chapter 2, Figure 2.3: *Arbalete* (crossbow), Baka Pygmies, Southeastern, Cameroon).

Hunting and butchering of wild non-human primates infected with Simian Immunodeficiency Virus (SIV) is thought to have sparked the HIV pandemic (Peterson, 2003; Wolfe, *et. al.*, 2004). HIV-2 and the sooty mangabey [*Cercocebus (torquatus) atys*] SIV are nearly indistinguishable, with distribution being the same from the West African Coast south from the Casamance River of Senegal to east of the Sassandraq River of the Ivory Coast (Côte d'Ivoire). However, the current HIV/AIDS global pandemic is 99% linked to HIV-I of which 99% of the infected people have HIV-1 group "M" linked to SIV in chimpanzees. Group "M" and HIV-1 groups "N" and "O", which appeared locally only, seem to have their foci in Central Africa (Cameroon, Gabon, Congo

Brazzaville and the western part of the DRC) and are all associated with the subspecies of chimpanzee (*Pan troglodytes troglodytes*) found in western Central Africa. The 30 SIVs and the two HIVs evolved out of non-human primate lentiviruses (*lentus* meaning slow – acting slowly). The common ancestral virus was introduced into primates hundreds of thousands of years ago. SIV is a misnomer because in primates there is no immunodeficiency, as the virus has lived in non-human primates for a long time. It is, however, virulent in humans where exposure is relatively recent (Peterson, 2003).

Bushmeat, as a major source of animal protein for much of Africa's rural poor and culturally preferred by the urban elite with rural roots, has the potential to be the source of more pandemic global outbreaks. Zoonotic infections with Simian Foamy Virus (SFV), a retrovirus endemic in most Old World primates, were identified in people living in Central African forests who reported direct contact with blood and body fluids of wild non-human primates. Contact with non-human primates, such as happens during hunting and butchering, can play a part in the emergence of human retroviruses (Wolfe, *et al.*, 2004). Ten of 1,099 individuals (1%) had antibodies to SFV. Sequence analysis from these individuals revealed three geographically-independent human SFV infections, each of which was acquired from a distinct non-human primate lineage: De Brazza's guenon (*Cercopithecus neglectus*), mandrill (*Mandrillus sphinx*), and gorilla (*Gorilla gorilla*), two of which (De Brazza's guenon and mandrill) are naturally infected with Simian Immunodeficiency Virus (SIV). This study indicates that simian retroviruses are actively crossing into human populations, and demonstrates that people in Central Africa are currently infected with SFV (Wolfe, *et al.*, 2004).

According to Peterson (2003), a 2002 study of 788 monkeys in Central Africa found that more than 20% of the blood samples tested positive for SIVs in 13 out of 16 primate species. This indicates that humans who hunt bushmeat are

exposed to a plethora of genetically highly divergent viruses, which can possibly jump to humans, thereby resulting in new epidemic outbreaks. Additional discussions on the bushmeat trade and its links to commercial logging concessions, as well as attempts to address this issue are contained in Chapter 10, Section 10.3.4, CITES Cannot Stop the Bushmeat Trade and Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks And Protected Areas.

5.9 OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY

“World War III has already started, between Africa and its environment, and it will claim more causalities than the first two wars and the exterminated Jews combined”, (C. Payne Lucas past director of the NGO AFRICARE In: Rosenblum & William, 1990).

In 1990, about 76% of the world’s population lived in Less Developed Countries (LDCs) generating 19% of the world’s Gross Domestic Product (GDP), while 40% of the LDC population was 15 years or younger. The Developed Countries represented 16% of the world’s population and generated 69% of the world’s GDP. By 2025, it is estimated that the median age in developed countries will be 32, while in developing countries it will be 15 years of age. Some call the developed countries’ populations the “old millions” and the developing countries the “young billions” (Huntley, *et al.*, 1989).

Based upon United Nations (1999) statistics, Africa’s human populations increased 6.0-6.8 times (1.9-2.0% annual growth rate) between 1900 and 2000 from about 117-133 million to 767 million people (Table. 5.12). Even with HIV/AIDS, Africa’s populations are projected to increase 2.3-2.7 times by 2050 to from +-2.2 billion people, reaching 2 billion people or more by 2100. This will

place tremendous pressures on land for agricultural purposes, especially if the majority of the population lives in a subsistence mode.

More precisely, Sub-Saharan Africa's population increased 5.5-6.5 times from 95.9-114 million⁷³ to 622 million, a 1.9% annual growth rate between 1900 and 2000. Sub-Saharan Africa's human population is expected to increase from 622 million in the year 2000 to between 1,497-1,753 million by the year 2050 and to between 1,944-2,750 million by the year 2100. By 2050, this is an increase of 2.4-2.8 times (1.8-2.1% annual growth rate) over the year 2000 population and by the year 2100 an increase of 3.1-4.4 times over the year 2000 population (Table 5.12) (United Nations 2004). A country by country profile is provided in Table 5.13, depicting the tremendous increase in population by country between 1950 and 2000. FAO (2002a) estimates that by 2030 "Sub-Saharan Africa will still be growing at 2.1%. By 2030, every third person added to the world's population will be a Sub-Saharan African. By 2050, this will rise to every second person".

It is believed that European populations once grew as fast as Africa's, but were stabilized through massive emigration to the New World, Africa, Australia and New Zealand, as well as through education (Rosenblum & Williamson, 1987). Few Africans have the option of emigration off the continent, though there is a large internal migration from areas with depleted resources (e.g., Sahel) to areas that possibly offer a better life (e.g., urban centers, coastal countries, South Africa).

With high infant mortality rates and no social security, large families assure that enough infants survive adulthood to take care of their parents in old age. Since

⁷³ Latest data provided by Kees Klein Goldewijk (Kees.Klein.Goldewijk@mnp.nl) of the Netherlands Environmental Assessment Agency (MNP) now independent from the National Institute of Public Health and the Environment of the Netherlands at <http://www.mnp.nl/hyde>. for 1900 an estimated population of 140,596 million for Africa, and 114,263 million or an increase of 5.5 times for Sub-Saharan Africa.

60-70% of the labor force is involved in subsistence agriculture, traditionally in a rural setting large families meant free/cheap labor to weed the fields and tend the livestock. They cannot control the weather, but they can control the labor supply (Rosenblum & Williamson, 1987).

Prepared by principal author

Rural America was no different as late as the 1920s before the “Great Depression” and the massive rural urban exodus that changed the face of the continent. The principal author’s 93 year old mother grew up in rural America with 11 brothers and sisters. The girls helped their mother in the vegetable garden and in canning during the summer around a coal stove in order to have food for the winter, as there was no refrigeration, only a cellar to keep things cool. The boys helped their father in the orchards. The large farm family in pre-WWII America and today’s Sub-Saharan Africa was/is an economically productive unit

of inexpensive labor, room and board. However, as in Sub-Saharan Africa, America was running out of farm land. After reaching adulthood, only one brother was able to farm full time; two farmed part time – one working in a factory at night and the other delivering mail in the morning; while the remaining eight had/wanted to leave for the towns and cities to earn a living.

The principal author's mother explains that in her opinion what transformed America was rural electrification (improved infrastructure) and a massive educational program after WWII through the "GI Bill" that sent many farm boys off to university. America was urbanizing and industrializing in a manner that absorbed these youth off the farm, took pressure off the land and helped create the current setting of a majority educated middleclass and their associated characteristics (e.g., significantly smaller families, healthy and well educated children, the development of an environmental consciousness). The principal author has over 30 first cousins, of which only one works in farming. If tomorrow, Americans were forced back onto the land to live subsistence lifestyles as they did in the first half of the 20th century, the USA would experience similar land hunger and associated environmental degradation. People would likely fall back onto the extended family for survival, and the consequences of these relationships that keep most Africans in a perpetual state of poverty (see Chapter 11, Section 11.6.3.3, Corruption and the extended family). The entire subcontinent is in a trap that at times seems inescapable.

Education, linked to the introduction of appropriate technologies in both rural and urban settings may be the only hope for Sub-Saharan Africa to get a grip on this population explosion and to develop the continent. Conservation and agriculture, to be successful, must fit into a big picture plan for Sub-Saharan Africa, and must be linked to adoption of modern agricultural technologies integrated into traditional knowledge, along with urbanization that is tied to diversification and

based upon transforming Africa's raw products, agricultural and other, on the continent. There should also be a leap into the information technology age. This is discussed more in Section 5.12, THE WAY FORWARD and forthcoming chapters. Ultimately, as the subcontinent becomes more educated and urbanized, implying the development of a larger middleclass, it is likely as in Europe and North America that family sizes will decrease.

However, if Africa remains stuck in "Phase I Agriculture" and does not evolve, the continent - ecologically, agriculturally and socially, is headed for a train smash. Given the existence of extensive agricultural and pastoral systems, unless this transformation takes place and results in a curtailment of the current population growth projections, both agriculture and conservation in general are doomed to failure. There is no reason for this transformation not to take place, as it did in North America and Europe during the 20th century, on possibly the resource richest continent in the world. However, this will require massive inputs in education and technologies. The question that must be asked is whether it is in the interest of the West to see Sub-Saharan Africa begin transforming the raw products that it currently furnishes them, thus diversifying and developing its own economies. This is probably not the case as epitomized by how development works (Chapter 11), current economic policies (Chapter 12), and relationships with the West in regards to the extraction and transformation of Sub-Saharan Africa's vast natural resources off the subcontinent (Chapter 13)!

For industrialized South Africa, this is another story. The rest of Africa's youth are flocking to South Africa's doorstep as they search for a better way of life not available to them in their own countries. Unfortunately, many do not have the education and South Africa, looking at transforming its own previously disadvantaged population, is being overwhelmed by this outside influx of people, pressurizing its housing, infrastructure, health and educational systems. To stem

this wave of poverty and hopelessness on its doorstep, South Africa may be the only industrialized country, which has a vested interest in exporting commercial agriculture and other technologies to the rest of the Continent to see it develop and give its hopeless masses, now out of kilter with their environment, some hope! There is only one caveat; South Africa must be careful that it does not become the next neo-colonial power, assuring that it bases this exportation of technology on appropriate environmental controls, reasonable salaries that can help create a middleclass, given the costs of living, training host country managers, and assuring that the wealth it helps generate is not expropriated by an elite but invested in the development of the continent. Ultimately, Sub-Saharan Africa must determine its own destiny instead of letting outsiders determine its future.

5.9.1 Over-population, Land Scarcity and Decreasing Agricultural Production in Sub-Saharan Africa

In Sub-Saharan Africa, when human and livestock populations were low, shifting cultivation (fallow) and transhumance pastoralism were appropriate to circumvent declining productivity. Colonialism, which brought in modern medicines and veterinary care and decreased tribal warring, brought about population explosions of both people and their livestock, which have had a major long-term adverse impacts on traditional management systems and associated natural resources, especially soils and vegetational cover. Due to limited land availability relative to population size and/or national regulations (e.g. centralization), these traditional management practices are no longer options over much of Sub-Saharan Africa.

By 1980, human populations in West Africa were already exceeding the carrying capacity of the land to support human populations living subsistence lifestyles (Table 5.14).

Table 5.14: Sustainable human population (no/km²) in West Africa under the traditional land uses of rainfed cropping, livestock production and natural forest cover

Zone	Under crops	Under livestock	Under natural forest	Actual (1980)
Saharan	0	0.3	0	0.3
Sahelian	5	2	1	7

Sudanian	15	7	20	19

Source: Steeds and Gore (1985 *In: de Haan, et al.*, 1997) with permission, UN& FAO.

According to de Haan, *et al.* (1997) in the

“Sahel, fuelwood is the most limiting factor in meeting the subsistence requirements of its human population. For the higher rainfall areas, livestock production remains below that necessary to satisfy subsistence requirements. For all the zones, however, fulfilling food subsistence needs with a combination of livestock and crop production (which is the normal situation) exerts less pressure on the land than satisfying fuelwood requirements”.

Long fallow periods of 5-20 years or more have become impractical because of increasing human and livestock populations. Losses of mineral nutrients during the cultivation phase, through runoff, erosion, leaching and crop removal, can no longer be restored by short periods of bush fallow of 1-5 years (Chirwam, Mafongoyo, Mbewe & Chishala, 2004 *In: Bationo, 2004*) or no fallow at all.

There appears to be a relationship between growing human populations and the degree of severity of soil degradation (Table 5.15).

Table 5.15: Land degradation severity and population density by region (Population density in number of inhabitants per square kilometer (km^2))

The 193 million ha in agriculture estimated for Africa in 1995 (Table 5.16) is mostly in subsistence fallow agriculture, implying for every ha in production anywhere from three to six times this in fallow, which is being rapidly reduced or disappearing. By 2000, it was estimated that Sub-Saharan Africa had about 5.2 million ha or 3.7 % of the arable land⁷⁴ under cultivation in irrigation (see Section 5.12.1.3, Irrigation potential). This also implies that Sub-Saharan Africa comprises about 135 million ha⁷⁵ of rainfed cropland on the continent in production at any one time. FAO (2002a) estimates that 228 million ha or about 223 million ha in rainfed agriculture in Sub-Saharan Africa were in production

⁷⁴ **Arable Land:** “land under temporary crops (double-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category. Data for “Arable land” are not meant to indicate the amount of land that is potentially cultivable” (FAO, 2003a). **Permanent Crops:** “land cultivated with crops that occupy the land for long periods and need not be replanted after each harvest, such as cocoa, coffee and rubber; this category includes land under flowering shrubs, fruit trees, nut trees and vines, but excludes land under trees grown for wood or timber” (FAO, 2003a). **Arable and Permanent Crops:** “The two added together” (FAO, 2003a)

⁷⁵ 5.2 million ha/0.037 = x/1; x = 140,540,000 ha – 5,200,000 ha = 135 million ha in rainfed crops

between 1997-1999. FAOSTAT (2004) indicates that there are between 166,973,000 ha in arable land and permanent crops or 146,598,000 ha in arable land (Table 5.17). If one assumes that for every hectare in production, 3-6 ha are in fallow, it can be assumed that the FAO (2003b) estimate of 596,491,000 ha of land in Sub-Saharan Africa that has no to moderate soil constraints for rainfed agriculture is likely already under some form of low-input agricultural production (e.g., in production or lying in fallow), and is likely degraded as fallow periods decline and/or disappear. A very small percentage, mainly in Southern Africa, and in 2006 mainly in South Africa (since Zimbabwe's commercial agriculture is in disarray as a result of radical land reform), is farmed commercially to produce food crop grains.

Sub-Saharan Africa has relatively little unused fertile land and much of the region is arid. By the year 2050, its population is expected to expand to the point that 812 million people (46-54% of Sub-Saharan Africa's population) will live in countries that are potentially short of fertile land and 1.1 billion (63-74% of Sub-Saharan Africa's population) in countries facing a potential scarcity of water. Modernization of agriculture and more efficient use of water will be required to avoid actual scarcity in these countries (CALTECH, 2002; Vogel, 2002).

It is estimated that by 2010, Sub-Saharan Africa agricultural fallow periods will have disappeared in 20 countries and will constitute less than 25% of arable lands in another 29 countries. Increased cultivation on less productive lands is a major cause of declining yields in many parts of Sub-Saharan Africa (Naseem & Kelly, 1999). Much of the current fallow agriculture, in which periods are ever shortening, is believed to be on marginal lands, which is the estimated 47.5% of Sub-Saharan Africa considered to have medium-low potential (see Table 5.5).

Population pressure is a major factor contributing to soil degradation and decreased productivity, and it is frequently but not uniformly linked to inequitable tenure systems. When land was more plentiful, traditional shifting cultivation/fallow agriculture was both a feasible and ecologically well-balanced system. As Africa's population has increased, so has the demand for land, and the fallow period has become shorter and shorter until, in many parts of Sub-Saharan Africa today, the land is being continuously cropped. In the absence of the regular replenishment of crop nutrients through fertilizers or organic methods, fertility has steadily declined and soil structure and water-retention characteristics have deteriorated (IFAD, 2002).

Per capita arable land has now declined from about 0.5 ha/person to less than 0.3 ha/person over the last 30 years in Sub-Saharan Africa (Winterbottom & Neme, 1997; Reich, *et al.*, 2001). FAO (1997b *In:* Barbier, 1998) estimates that there is 0.27 ha of arable land per capita in Africa (Table 5.16). CIAT (2002) estimate a per capita decline/ha of available agricultural land from 0.38 to 0.25 in the last 20 years in Sub-Saharan Africa. As a result of a major rural to urban migration in the 20th century linked to industrialization, in North America decreasing land per capita is not a problem, as less than 2% of the people farm to feed the majority living in urban settings so farms are large and commercially run (Ward, 2002).

Alemayehu (2000) states that 1.4% of the U.S. population (3.4 million) were farm workers in 1995. Europe is in a similar situation.

However, in Africa, with 60-70% of the labor force living subsistence lifestyles from agriculture (Roman, 2003), this is catastrophic. The human population increases in rural Sub-Saharan Africa have resulted in small economically unviable plots of land at the level of the household, forcing people to abandon fallow, mine the soils, emigrate to urban centers in search of work to support the rural family through remittances and ultimately to begin accessing marginal agricultural lands best employed for other land uses (e.g., wildlife/livestock, forestry, watershed protection). The latter often places small-scale farmers in conflict with other resource users, as well as results in major habitat degradation. As this form of agriculture, which has not changed for the past 2000 years, results in soil exhaustion and crop failure, often the only thing left is to send children to work for someone else. Studies have shown that cultures dependent upon subsistence farming have the highest rates of child labor, in most cases these victims of this “poverty trap” being denied a formal education – condemned to an endless cycle of poverty passed on from one generation to the next (Wax, 2006).

Decreasing land per capita has occurred despite widespread conversion of forest and wetlands to cropland, the extension of farming onto marginal upland soils (Winterbottom & Neme, 1997) and expansion into traditional pastoral areas. In most countries, poverty increases among the rural population with decreasing land per capita (IFAD, 2002). Poverty tends to be concentrated in households with farm sizes under one ha, and especially under 0.5 ha. For instance, in Malawi, over 40% of smallholders cultivate less than 0.5 ha, with an average farm size of 0.28 ha. However, in drier areas, average smallholder farm size is larger, sometimes reaching 5-8 ha, but low land productivity under conditions of limited

rainfall means that these farms may not even cover household subsistence needs (IFAD, 2002).

Martin and O'Meara (1995) believe that population rather than environment (e.g., global warming, El Niño, etc.) is the most serious cause of continuing poverty in Africa. The population is outstripping the growth of economies (e.g., declining per capita GDPs), and growing population pressure on the resource base is leading to environmental degradation, and the reduction of carrying capacity of the land. Likewise, Virmani, Katyal, Eswaran and Abrol (1994 *In: Reich, et al.*, 2001) believe that land degradation in Africa is clearly human induced (e.g., over population resulting in decreasing agricultural fallow and over-grazing). They also believe that there is increasing evidence that land degradation is a driver of climate change. Reich *et al.* (2001) also concluded for Africa that:

1. Under low-input systems, the potential productivity of the soils cannot be realized and additionally stability of production will be difficult to achieve. A systematic decline in productivity is the result of degradation processes;
2. Desertification is rampant on much of the continent and will permanently destroy the agricultural production potential. Correcting the degradation effects will be more expensive and the low resilience characteristics of many of Africa's soils suggest that high levels of productivity cannot be expected even after mitigation technologies are used; and
3. Under current cultivation and land-tenure systems, most of Africa's countries will be unsustainable in agriculture and if desertification is not controlled, their ability to attain sustainable food production will be significantly reduced.

The risk of desertification is highly linked to hunger, malnutrition, land hunger and the search for new economic opportunities, resulting in political destabilization. (see Section 5.7.4.4, Land reform and civil war in the Ivory Coast and Section 5.11, CONFLICT LINKED TO OVER-POPULATION AND DESERTIFICATION).

Land scarcity as projected for 2050 (CALTECH, 2002) is already an issue in many African countries as fallow periods disappear or decline due to increasing human populations.

Rosegrant, *et al.* (2001) indicate the following Sub-Saharan countries still have significant amounts of high potential land that may be available for agriculture (Table 5.18).

Table 5.18: Countries in Sub-Saharan Africa with significant amounts of remaining high-potential arable land, 1994

Northern	Central & Western	Southern	Eastern
Chad	Benin	Angola	Tanzania
Ethiopia	Cameroon	Lesotho	Uganda
Mali	Central African Republic	Madagascar	
Sudan	Congo Republic Ivory Coast Democratic Republic of Congo Gabon Ghana Guinea-Conakry Liberia Nigeria Togo	Malawi Mozambique Swaziland Zambia Zimbabwe	

Source: FAO (1994) In: Rosegrant, Paisner, Meijer and Witcover (2001, Table 6.10), with permission, International Food Policy Research Institute (IFPRI).

More than 50% of the land that could be opened up is in just seven countries of tropical Latin America and Sub-Saharan Africa (FAO, 2002a), indicating that the majority of Sub-Saharan Africa's arable land is already in use. In Sub-Saharan Africa, this includes Angola, the DRC and Sudan. FAO (2002a) states that while there is still surplus land in these regions, expansion may involve cutting back on

long rotation and fallow periods. In other words expansion means intensification of agriculture by placing fallow land, where there are “no to moderate constraints”, into permanent use through the use of fertilizers, pesticides, genetically modified crops, double cropping, crop rotation, etc. (see Section 5.12.1, Technological Solutions to Africa Food Crisis and Land Degradation). If fertilizer use does not significantly increase, this will likely result in soil mining and stagnant or declining yields (FAO, 2002a) on lands placed in permanent agriculture without the luxury of allowing the land to recover its fertility through long fallow periods.

5.9.2 Over-Population of Prime Agricultural Land for Low Input Agriculture is also Commercially Viable Land

Much of the prime and high potential lands for low-input agriculture shown in Figure 5.4 (Eswaran, *et al.*, 1996) also appear to be the same geographical areas that have high yielding high-input commercial potential to produce food to feed large areas of Africa:

- The high yielding high altitude grasslands of South Africa, Zambia, Zimbabwe, parts of Mozambique, Tanzania (e.g. Serengeti/Maasailand) and Kenya (e.g., Mara) that respond to high-input agriculture;
- The highlands of Rwanda, Burundi, Tanzania and Kenya; and
- The Sudano-Guinean rainfall zones of West Africa (e.g., the Ivory Coast, southern Burkina Faso, southern Mali, Ghana, Togo, Benin and parts of Nigeria), as well as along major floodplains (e.g., Niger, Senegal, Gambia Rivers).

Based on this information, between 11% (Eswaran, *et al.*, 1997a; 1997b both *In:* Reich, *et al.*, 2001) and 16.3% (Eswaran, *et al.*, 1996) of the land in Africa, 27%

in Sub-Saharan Africa, if properly managed through 1) traditional low-input fallow agriculture, 2) modern commercial high-input agriculture, or 3) improved traditional agriculture linked to Integrated Nutrient Management (INM), should be considered as critical agricultural land. The remainder of land is mostly savanna (70-75% of Sub-Saharan Africa) managed as fallow agriculture, which, as discussed, appears to no longer be sustainable given low resource/population ratios that are resulting in reduced/eliminated fallow and over-grazing across the savannas of the continent. As noted by Reich, *et al.* (2001), in these marginal savanna lands, it is likely that high levels of productivity will not be achieved even after mitigation technologies are used

Unfortunately, many of these high potential lands are already over-populated with both people and livestock, diminishing their potential for high yields for a number of reasons when used for low-input agriculture (e.g., loss of fallow, nutrient mining, soil erosion, etc.), or in the case of Zimbabwe because of the internal politics linked to land reform. For instance, the civil war in the Ivory Coast, disrupting agriculture, is a land issue as land hungry outsiders from countries like Burkina Faso have flocked into this country (see Section 5.7.4.4, Land reform and civil war in the Ivory Coast). A large area of quality soils appears to be in Nigeria, which by about 2050 will have a population of from 258 million (Brown, 2003a) to 307.4 million (Pop. Ref. Bur., 2004), about the population of the USA in 2004 in a country the size of Texas, with the total population of Sub-Saharan Africa by 2050 ranging from 1.5 to 1.8 billion people (United Nations, 2004) (see Section 5.11.2, Over-population, Desertification and Instability, Nigeria). Nigeria alone will contain somewhere between 14-20% of Sub-Saharan Africa's population. Unless intensification of agriculture occurs, these high potential soils will likely be rapidly depleted, if this is not already the case. On a positive note, the Nigerian government has invited Zimbabwean white commercial farmers to settle there as long as they act as "mentors" to train traditional farmers in

commercial intensive farming techniques (BBC, 2004; Bridgland, 2004). Meanwhile all along the coast of West Africa, there is a major exodus out of the land degraded Sahel that could rapidly over-crowd and deteriorate the high potential soils from Ivory Coast to Nigeria, as indicated in Figure 5.4 (see Section 5.7.5, Food Security and Urbanization in Sub-Saharan Africa). Thus, these areas will require the application of modern agricultural practices to maintain their soil fertility and thus productivity.

5.9.2.1 Over-population of prime agricultural lands in the Highlands of East Africa

“The most productive agricultural areas of the region are in the moist sub-humid and humid climatic zones. The mountainous areas have more rainfall and are more productive. Small-scale farmers grow cereals such as wheat, barley and maize in the highlands of Ethiopia and Kenya, and these areas support relatively dense populations. Lower-altitude areas in this moister zone support root crops, plantain and coffee, while in the coastal areas, coconut, cashew, root crops and fishing are the main sources of livelihood.

The high-rainfall and potentially highly productive areas include more than half of Uganda and Rwanda, and quite large areas in Ethiopia, Kenya and Madagascar. These areas support tree crops such as coffee, palm oil and cocoa, as well as bananas, rice and sugar cane where the temperatures are suitable. About 54% of the region’s poor live in these areas” (IFAD, 2002).

There is a concentration of high quality lands in West and East Africa, including parts of the Central African Highlands, though these areas have high population densities. Population pressure and land degradation are major problems which go in tandem and both must be addressed together to continue sustainability. For instance, human population pressure and subdivided farms in the highlands of Kenya, Tanzania, Ethiopia, Rwanda, Burundi, western Kenya along Lake

Victoria, southwestern Uganda, etc. are lowering this potential considerably under current conditions.

Adams and Infield (1998) argue that in the Kisoro District of southwestern Uganda, agricultural problems include a land shortage resulting in reduced fertility from continuous cultivation, land fragmentation with one farmer having a number of distantly separated plots, no pesticides, lack of improved seeds, no money to buy or training in how to properly apply fertilizer, inadequate agricultural extension, not enough manure as fertilizer, lack of mulching grass from over-grazing, labor shortages and distant markets with inadequate transport.

In the case of Kenya (see Chapter 3, 3.11.1, Population, Kikuyu and the Mau Mau), even during the colonial days by the middle of the 20th century, land hunger was a problem from compression through confiscation of land by settlers, land subdivision and increasing human populations. Land hunger constituted one of the key reasons for the Mau Mau uprisings. Kenya is being squeezed by spreading deserts and desertification. “As elsewhere, the unholy triumvirate of over-grazing, over-plowing and over-cutting of trees is contributing to the loss of productive land” (Brown, 2003a). While land hunger is a major issue for the Kikuyu farmer, forcing him into less productive areas such as Maasailand (see Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya) and the Laikipia Highlands (see Chapter 11, Section 11.11.9.4, Human/wildlife conflicts), Ian Parker (2007a) argues that

“that fragmentation (of land) notwithstanding, production per unit area in the Kenya highlands has consistently risen since independence: i.e. more is being produced off less. At the same time prices for produce have risen...at some indeterminate date in the future ‘the wheels will come off’. The difference between Kenya and Southern Africa is that here we exist on fertile volcanic

geology with deep soils and two rains a year, while there you (Southern Africa) live on ancient, very infertile cratons and a single annual rainfall. In relative terms all the bad points will come earlier in Southern Africa" (see Section 5.5.2.3, Nutrients, pH, acidity and carrying capacity).

The major thrust of national and regional strategies must focus on maintaining the high productivity of these lands, which calls for assisting the farming community to move up to medium-input systems. These lands will be most responsive to the introduction of high yielding cultivars and modern pest and weed management techniques (Eswaran, *et al.*, 1996).

Over-Population of Prime Agricultural Land in Ethiopia

It is estimated that deforestation in Ethiopia is 1,000 km²/year, the forest having been reduced from 40% of the surface area by the 1900s to 2% by the 1990s (Alemayehu, 2000).

"The tropical highlands, as in Ethiopia, Lesotho and Cameroon (Central Africa), have rainfed agricultural systems based on small-seed cereals, pulses and oil crops. Animal power is often used for land preparation. Soil degradation is a major problem for these mountainous environments. Traditionally this is tackled by a combination of crop rotation involving legumes, the application of animal manure and allowing animals to graze harvested fields, as well as fallowing usually for one or two years...Nowhere is the lethal interaction of poverty and environmental degradation more evident than in Ethiopia. About half of the country's highland area is significantly eroded, reducing yields by between 2 and 3% a year. According to a 1986 study by the UN Food and Agricultural Organization (FAO), over 1,900 million tons of soils are lost from the highlands annually. If the trend continues, some 38,000 km² (3.8 million ha) will be eroded down to bare rock by the year 2010, and a further 60,000 km² will have a soil depth of 10 centimeters, below which the soil would be too shallow to support cropping. About 2 million ha of farmland are already estimated to be beyond recovery" (Nana-Sinkam, 1995).

Similarly Brown (2003) states that Ethiopia “is losing an estimated 1 billion tons of topsoil a year. This is one reason why Ethiopia always seems to be on the verge of famine, never able to accumulate enough grain reserves to provide a meaningful measure of food security”. Population pressures and agricultural practices also have major implications with regard to biodiversity and deforestation (see Section 5.9.4.6, Deforestation in afromontane forests - Deforestation in the Ethiopian Highlands).

Population and Conflicting Land Uses, High Altitude Grasslands of East and Southern Africa

“The dry sub-humid climate zone includes vast savannas at varying altitudes, where rainfed cereal production dominates the cropping system. At altitudes of 1,000 meters or more, the savannas provide relatively cool temperatures (for the tropics) and allow a variety of crops. In their moister areas, the savannas support a maize-based mixed farming system, giving rise to the great maize belt of the region, which takes in large tracts of Angola, Kenya, Lesotho, Malawi, Mozambique, Swaziland, Tanzania, Zambia and Zimbabwe. About 32% of the region’s rural poor live by these maize-based farming systems” (IFAD, 2002).

Many of these areas may be considered high altitude grasslands that have a high potential for commercial agriculture. “Grasslands are defined as those areas where grasses dominate the vegetation and where woody plants are absent or rare” (DEAT, 2001).

This should also include the temperate grasslands of South Africa/Lesotho, which consist of 349,174 km² of which 49% has been turned into agricultural lands producing maize, sunflowers or other crops (O’Connor & Bredenkamp, 1997 *In: Cowling, et al.*, 1997). “Grasslands cover the high central plateau of South Africa, inland areas of KwaZulu-Natal and the mountain areas of the Eastern

Cape Province". They occupy 24.1% of South Africa's surface area (DEAT, 2001). A relatively new but serious threat to these South African grasslands is tree plantations for pine (*Pinus. spp.*) and eucalyptus (*Eucalyptus spp.*) in the higher rainfall areas of the eastern plateau (O'Connor & Bredenkamp, 1997 *In: Cowling, et al., 1997*), mostly for export to the Far East. In Southern Africa, the high altitude grasslands of South Africa, Zimbabwe and to a lesser degree Zambia will be critical in the long run to helping the region achieve a level of food self-sufficiency through assuring that these areas are retained for commercial agriculture. Currently, South Africa is the only country in Sub-Saharan Africa that can feed itself. However, drought conditions in 2007 could force South Africa to import between 1.4 and 1.8 million tons of maize.

A major problem with these high altitude grasslands is that they are often prime pockets of biodiversity, and can be in conflict with conserving areas for Africa's mega-fauna and traditional pastoralists.

"For instance in South Africa: the grassland biome (24.1% of South Africa's surface area) is regarded as the third-richest area in terms of plant species diversity, with a total number of 3,788 species. The most noteworthy species with a wide distribution is, *Themeda triandra*, more commonly referred to as *rooigras*. In the past the ungulate fauna (hoofed animals) of the Highveld grasslands included vast herds of blesbok (*Damaliscus dorcas phillipsi*), black wildebeest (*Connochaetes gnou*) and the springbok (*Antidorcas marsupialis*). A surprisingly rich variety of birds are found in the grasslands, including the blue crane (*Anthropoides paradiseus*), black korhaan (*Eupodotis afra*) and helmeted guineafowl (*Numida meleagris*)" (DEAT, 2001).

As noted, long ago, South Africa made a decision that much of this land would be devoted to food production.

Southern Maasailand of Tanzania and Maasai Mara, Kenya, are facing increasing threats from both an invasion by small-scale farmers moving into more marginal areas as the highly productive highlands become over-populated, and from commercial wheat and seed-crop schemes as well as winter vegetables and cut flowers for European markets. The trade off is the loss of critical wildlife habitat – in many cases rainy season dispersal areas for game from national parks, the bottleneck to carrying capacity for these parks (Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya and Chapter 9, Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”). Also, see Chapter 3, Section 3.11.1, Population, Kikuyu and the Mau Mau.

Also, while human populations may be comparatively low/km², the increase in humans in the 21st century, changes in land tenure, and land compression from the creation of parks and protected areas (see Chapter 3, Section 3.8.4, Land Compression and the Maasai of Kenya and Tanzania and Chapter 11, Section 11.10.6, Eco-Colonialism-Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers), and increased livestock numbers are resulting in over-grazing and major habitat degradation in these areas as well as the loss of prime wildlife habitat. This applies to both dry and rainy season grazing areas.

5.9.3 Fallow Agriculture, Over-Population and Agricultural Production

The following image of “slash and burn” agriculture, primarily in the Democratic Republic of Congo, visually depicts the problem with traditional fallow agriculture in Sub-Saharan Africa as discussed above; too many people, not enough land, decreasing fallow periods, soil degradation, decreased crop yields, deforestation and adverse impacts on climate from decreased vegetational cover,

decreased transpiration and clouds of smoke pouring into the atmosphere all over the continent (Figure 5.9).

5.9.3.1 The Sahel, over-population and declining fallow periods

“The most salient impact is the increase in human and animal population that followed the application of Western medicine. The people of the Sahel are increasing at a rate of 2.5% a year, one of the highest rates of population increase in the world” (Hardin, 1977).

“Over the past 25 years, both human and animal populations have grown rapidly at average annual rates of 2.6 and 1%, respectively” (FEWS, 1997).

“Between 1960 and 1990, the region's total population grew from 85 to 193 million people...The rural population affected by the activities of rural development was, in 1990, a little over 30 million. Today (1996) the figure is approximately 35 million, distributed among some 50,000 villages or encampments” (Snrech, 1996).

In the Sahel portion of Sub-Saharan Africa, it is estimated that only 8% of the land area is suitable for agriculture, and irrigated agriculture (traditional recession, and modern) currently occupies only about 5% of this land (5% of 8% or 0.4% of the land suitable for irrigation)(Moore, *et al.*, 2000). Similarly, FAO estimates that only 4% (212,000 ha) of the Sahel's 5.3 million km² is suitable for agriculture; while at the other extreme, 64% of the Sahel's land mass is completely unsuitable for agriculture. Most of the population lives between the two extremes on the 32% of the land considered marginal for rain-fed agriculture, using it for crops, pasture, and fuelwood (FEWS, 1997).

Fallow has been reduced from 10-15 years to one to two years or has disappeared altogether, resulting in declining food and cash crop yields and pushing farmers onto marginal lands. This often results in conflicts with traditional herders who

use these areas as rainy season grazing lands. Despite the semi-arid zone's low theoretical support capacity, population density is often higher than in sub-humid and humid agro-climatic zones of Sub-Saharan Africa (Moore, Kabore, Gnoumou & Bertelsen, 1999; Moore, *et al.*, 2000).

Traditional Knowledge and Fallow Agriculture

The savanna farmers have a comprehensive knowledge of their environment. Over centuries, through a system of trial and error, they determined how to balance their demands on the natural resources and the ability of the resources to satisfy their basic needs. They can relate the fertility status of the land and its suitability for one or another crop to the vegetation which covers it and the physical characteristics of the soil. They can also assess the staying power of the soil i.e. the number of seasons for which it must be rested before good crop yields can be obtained again. Traditionally, peasant farmers have coped with Africa's fragile ecology by leaving soils fallow for long periods and developing complex inter-cropping systems, designed to minimize risk and maximize sustainability (see Chapter 2, Section 2.3.2, Pasture and Water and Section 2.3.3, Fallow Agriculture in Low Productive Areas). Today, these systems are breaking down in the face of a range of mutually reinforcing local, regional and international pressures. In the savanna, one of the best ways of maintaining soil organic matter is by fallowing. First, a variety of short-lived herbs appear. These early colonizers tolerate the daily extremes in temperature and water stress and provide the conditions for the establishment of other plants including legumes. Once legumes appear in the system, both nitrogen and organic matter increase. Left alone, the sequence of plant appearances would continue until stable climax vegetation is established. It is mainly population pressure that has caused this system to break down, resulting in devastating soil degradation given the terrifying name of desertification (Nana-Sinkam, 1995).

Fallow Periods Disappearing in the Gambia

With the exception of irrigated rice fields and domestic gardens, agricultural land use is generally extensive, in the meaning of low/few inputs and low returns. “Slash and burn” of bush or fallow land subsistence agriculture is the norm. The traditional means of keeping soil fertility at satisfactory levels are shifting cultivation and inter-cropping. Shifting cultivation includes using fallow periods and crop rotation. In the Gambia, traditionally the soil was subject to a fallow period of over 20 years after four years of cropping (Fyhri, 1998; Hennig, 2000).

“A typical cycle of crop rotation in The Gambia featured groundnuts in the first year, thereafter late millet, early millet or sorghum and finally groundnuts again. Finally, inter-cropping is common in The Gambia. Inter-cropping of different crops, with differing demands of water and nutrients, is an effective way to postpone soil exhaustion. In The Gambia, inter-cropping of groundnuts with millet and maize, early millet with late millet and maize or sorghum with late millet are somewhat common. Single cropping, with the exception of sorghum, is however getting more and more the norm. While crop rotation, and to some extent inter-cropping, still is widely practiced throughout The Gambia, long fallow periods are coming to an end. From a traditionally fallow period of over 20 years, they had dropped to one or two years in 1983, having severe effects on soil fertility. Now, many fields do not experience fallow periods at all” (Hennig, 2000).

Decreasing fallow and expansion into marginal areas has had a major impact on forest cover (Table 5.19).

“Applying organic fertilizers (manure) has been a traditional means of upgrading soil fertility. Almost 50% of farmers used this method in 1982, but numbers are probably higher today. The use of chemical fertilizers is not widespread in The Gambia” (Hennig, 2000).

**Table 5.19: Changes in vegetation types over time, The Gambia
Land use classes: Coverage of The Gambia (%)**

Closed forest	Open forest	Savanna	Cultivated areas	Other areas
1980 2,64	7,60	42,35	25,81	21,60
1988 1,53	4,92	40,20	31,34	21,71

Fallow Land Management Compromised by “Subsistence Ethic” in Two Senegalese Villages

In this case study (Grigsby, 2001), which was undertaken in two villages near Tambacounda, the control and management of the fallow period by the household is made difficult due to increasing population pressures, and the “subsistence ethic” under common property management to “lend” your fallow land to a needy neighbor in the community, even if this land has not completely recovered. Thus, as populations increase, control over fallow becomes more difficult.

Bush fallow agriculture is the principal land use, with fallow periods ranging from 3-25 years and three to four years of cultivation. The area is part of an ecological belt of dry woodland, and natural and derived savanna that stretches across the continent, and the portion in Mali and Senegal comprises many ethnic groups practicing variants of sedentary bush fallow. Rainfall ranges from 500 - 1500 mm during a three to five month growing season, arranged along a north-south gradient, placing it in the Sudano-Sahelian Zone.

The cultivation cycle's principal yields are millet and peanuts. During a fallow succession from grass species to woody vegetation, accumulation of biomass and greater nutrient retention in trees and shrubs represent the principal means of restoring soil fertility. The fallow cycle yields a wealth of "secondary" resources (e.g., fodder, fuel, food, construction materials) exploited both for local

consumption and market sale. Bush fallow as a land use is complemented by other land uses important to the productive enterprise, such as forestland, fenced gardens, “backyard fields” (*sokofeforow*) and low-lying rainfed draw areas.

Land inheritance is patrilineal. Male household heads, who allocate land first and foremost to the cultivation of household grains, largely control land, labor and equipment. Household heads hold many tenure rights, including rights to control or transfer customary fallow or create tenure (clearing forestland), and the right to control access to claims made by household members and others on bush fallow lands, which comprise the vast majority of land devoted to household grain production. Transferring land outside a lineage is only reported in instances where land-rich households are helping a newly immigrated household settle into the village. The village chief may also designate livestock corridors in an effort to protect household grain fields during the growing season. Important but relatively low-impact uses may include sacred forests and cemeteries.

Villagers reported increasing pressure on land, for three reasons: more people are participating in household subsistence activities, village populations are growing, and some households have increased hectarage via animal traction and plow farming. The head of household “A” can clear and cultivate his own fallow claims. He can also make a valid claim to clear and cultivate fallow (presumably in some stage of recovery) claimed by household “B”. However, household “A’s” exclusive rights to that fallow are limited seasonally to the growing period and ultimately by declining soil fertility. The head of household “B” retains long-term rights to the fallow, but may find it difficult to refuse access to would-be tenants so long as the parcel is not currently under cultivation. Thus, long-term tenure security may be punctuated by tenancies and crop rotations of varying frequencies. This would seemingly complicate any efforts to actively manage fallow.

While the subsistence ethic may discourage many economic-based innovations in resource and agricultural production and accommodate ecologically unsustainable resource use, it is an important concept linking access to resources with cultural and material survival. At the household level, the subsistence ethic appears to discourage an overt strategy of accumulation, exerting subtle pressures to make land and resources that are not currently used available to others, presumably for subsistence (Grigsby, 2001). However, given today's human populations in Senegal, there is apparently not enough land to allow everyone to farm without greatly reducing fallow, resulting in soil mining and ultimately reduced yields and degradation. In 2003, the Senegalese National Shooting Team (*pers. comm.*) was in South Africa for the African championships. The principal author, who had been a member of the *Association Darkois du Tir* (ADT), met with the team and they explained that the rural to urban exodus had accelerated to the point that Dakar was maybe 10 times the size in human numbers compared to the 1980s when the principal author lived there. During the week, the only way to get around Dakar is via môtô scooter or to walk, as the traffic is so jammed. They explained that there was little future for most people in rural Senegal.

Impacts of Over-Population on Agriculture in Southern Burkina Faso

Once the land constraint becomes binding, however, as in the case of the Mossi Plateau region in the Sahelian portion of Burkina Faso, yields and production decline contributing to urban migration (Vlek, 1993 *In: Gruhn, et al., 2000*). René Dumont (1966) believed that in the Sahel, outside of areas with irrigation potential (e.g., floodplains), efforts to intensify agriculture would be of very limited value. He states, as is occurring, that stepping up of massive agricultural migration would be necessary to “decongest” the Sahel by moving populations towards plantations in the forest zone. The question is at what cost would this be

to these higher rainfall areas south of the Sahel, if their carrying capacities are also exceeded by this influx, while continually practicing low input cultivation?

In the Mossi plateau region, population densities range from 90 – 120 persons/km². This pushes people from over-populated areas to less populated areas, accelerating land degradation. For instance, around the Comoé-Leraba Game Reserve of southern Burkina Faso on the edge of the Sudanian and Guinean rainfall zones, “slash and burn” low-input agriculture of *igname* (yam) provides one-year of production followed by 10-years of fallow. This area is being inundated by small-scale farmers from the north, placing tremendous pressure on the “land chiefs” to allow people to cultivate in the game reserve (Pavy, *pers. comm.*) (see Chapter 9, Section 9.8.9.1, Management of Comé-Leraba Game Reserve, southern Burkina Faso). It is also believed that a large portion of the Ivory Coast’s civil war can be linked to the heavy migration of Burkinabé from the overpopulated north, placing tremendous pressure on the Ivorian economy, natural resource base and infrastructure (see Section 5.7.4.4, Land reform and civil war in the Ivory Coast).

5.9.3.2 Loss of fallow turning wildlife into a short-term resource, Fouta Djallon Mountains, Guinea-Conakry

By the mid-1980s, 25 years of Sekou Touré’s repressive regime had flirted with communism, run off or killed most intellectuals, and run the country into the ground economically. People were trying to survive and in doing so auctioning off their future. The Fouta Djallon Mountains were over-populated. Only small plots *tapades* or *sunture* near the home using “green manure” to produce vegetables by women were viable. Twenty-year fallow periods of extensive agriculture were disappearing, not allowing the lateritic soils to recover from acidification, nutrient leaching and aluminum/iron toxicities. Yields from *tapades*

were more important for household provisioning than from other fields. Most land would no longer support the traditional crops of sorghum and millet, requiring cultivation of the lower yielding wild grass cereal called *fonio*, *Digitaria exilis*. In the prefectures (districts) of Labé, Koubia and Mali (borders Senegal), through inter-cropping, *fonio* was grown on 95% of the fields (outside of *tapades*), groundnuts on 37%, rainfed rice on 17% and sorghum on 8%, indicating the likelihood of massive degradation in these areas. *Fonio* was second only to rice as a food crop. The 55% increase projected in land cultivated between 1984 and 2000, necessary to maintain the population increase at the 1984 per capita food output would likely occur only by a drastic reduction in fallow periods. At the time, per capita land under cultivation was only between 0.18 ha in the high population density area around Labé and 0.37 ha in the region of Koundara, Guinea-Conakry, averaging 0.24 ha/per capita for the entire Gambia River Basin. People were slashing and burning into virgin forests that served as important cover for the watersheds supporting major dams being planned/existing on the Senegal and Gambia Rivers (University of Michigan, 1985a) (see Chapter 7). Cereal demands in the Gambia River Basin portion of the Fouta Djallon, Guinea-Conakry were projected to climb to 116,000 metric tons by 2000, whereas they were only producing 78,000 tons at the time of the study (University of Michigan, 1985b). Neighboring “*Haut Guinea*”, the watershed for the Niger River, is believed to be in a similar situation. Revenga, Murray, Abramovitz and Hammond (1998) estimate that 96% of the original forest⁷⁶ in the Niger River Basin is gone and that deforestation is taking place at 6%/year. Fairhead and Leach (1996 *In: McCann, 1999*) argue that what many consider forest is fallow land and not virgin forest. The real question arises, virgin or secondary forest on fallow land, to what degree are fallow periods declining? Declining fallow implies more land in

⁷⁶ Original forest cover refers to an estimate of the extent of closed canopy forest in existence 8,000 years ago, assuming current climate conditions. Current forest cover refers to amount of closed canopy forest in existence today (Revenga, Murray, Abramovitz & Hammond, 1998).

agriculture and less in forests at any one time and in the long-term soil mining and decreasing agricultural productivity under traditional low-input systems.

Due to increasing populations, decreasing agricultural production and increasing desires to enter into a moneyed economy, among others, wildlife was also being mined as a short-term resource and was more valuable than agriculture. As one Fulani Marabout lion hunter in the Guinea-Conakry highlands explained to the principal author in the mid-1980s,

“You may think it wrong of me to hunt lion for a living. You get paid every two weeks down in the big city in your air-conditioned office. For one lion skin, I get what I make out of the ground in a year. You can put me in jail but when I get out, I will do it again. I have a wife and children to feed. You have one of two choices if you wish me to stop. You can shoot me now or find me another way of life” (DeGeorges, 1992).

5.9.3.3 Over-population and loss of fallow putting pressure on Park “W”, Niger

“Conflicts exist between indigenous livestock husbandry and nature-conservation areas, as evidenced in the case of “W” National Park” (Lycklama à Nijeholt, *et al.*, 2001). “In this instance, herders want to go inside the park because of the scarcity of pastures outside (due to increasing agricultural surfaces). The park is the only grassy place at the end of the dry season. As a matter of fact, the presence of livestock in the park reduces herder-farmer conflicts outside. The prohibition on clearing fields in the park has increased or saved the availability of grass. While officially this grass is not accessible to herders, it is in practice (Benoit, 1999 *In:* Bourgeot, 1999)” (*In:* Lycklama à Nijeholt, *et al.*, 2001).

On the downside, it is believed that the tens of thousands of cattle enter the park, since expanding agriculture excludes herders from former dry season grazing on the park’s periphery (East, 2005).

5.9.3.4 Over-population and livestock, a threat to wildlife in Northern Cameroon

People were relocated from the over-populated Extreme North Province to the Northern Province of Cameroon. Their implication in cotton production for the French/Cameroonian government SODICOTON Company is slowly encroaching on 28 hunting blocks that serve as a buffer for three national parks. It is estimated that areas covered by cotton increased from about 14,000 ha in 1988 to nearly 30,000 ha in 1996 (Saidou, 1998).

This is an important pocket of biodiversity in Northern Cameroon. This Western Africa forested savanna preserves a typical woodland fauna including game species such as large ungulates Lord Derby Eland (*Taurotragus derbianus gigas*), Western Roan/antelope *cheval/koba* (*Hippotragus equinus koba*), sing-sing waterbuck/*kob defassa* (*Kobus defassa unctuosus/Kobus defassa defassa/Kobus ellipsiprymnus unctuosus*), western hartebeest/*bubale* (*Alcelaphus buselaphus major*), *cob du buffon* (*Kobus kob kob*) and harnessed bushbuck/*guib harnaché* (*Tragelaphus scriptus scriptus*), as well as the West African savanna buffalo (*Syncerus caffer planiceros*), hippopotamus (*Hippopotamus amphibius*), lion (*Panthera leo*), a few remaining western black rhino (*Diceros bicornis longipes* – may be extinct by now??), savanna elephants (*Loxodonta africana africana*) and the wild dog (*Lycaon pictus*). The key protected areas include the Faro (330,000 ha), Bénoué (>180,000 ha) and Bouba-Njida (220,000 ha) National Parks.

As human populations grow, demand for land grows, while rural communities see little or no long-term value in wildlife. As all over Sub-Saharan Africa, the combination of turning 44% of Cameroon's Northern Province into parks and protected areas (Gomse, 2003), resulted in compression of human and livestock populations. At the same time artificially increasing the human and livestock

populations through relocation programs from an over-populated Extreme North Province (Province d'Extrême Nord) in the 1970s (Saidou, 1998) has been a recipe for disaster. This has resulted in habitat degradation outside protected areas and encroachment into these areas by an ever-expanding population, especially by small cotton farmers.

Currently, uncontrolled immigration is resulting in the Northern Province having the highest population growth rate in Cameroon at 4.3% (Saidou, 1998). Poaching and illegal firewood collection is a major problem in both the parks and hunting areas (Saidou, 1998). East (1998) raises concern that land fragmentation resulting from this relocation is a major risk to the Lord Derby eland and other populations of wildlife in the three parks and their hunting blocks. Inadequate grazing land, especially in the dry season, exists for Fulani herders. Though, not officially sanctioned, the head of Bénoué National Parks allows herders in to graze during times of extreme drought (Gomse, *pers. comm.*). The recent development of co-management agreements between peripheral communities and MINEF is facilitating the negotiation for access to natural resources inside these protected areas (Tarla & Bachirou, 2004).

Thus over-population, commercial cotton farming and increasing livestock populations, combined with a loss of traditional controls (see Chapter 11, Section, 11.11.6.1, Introduction), threaten wildlife in the Northern Province unless these areas and associated wildlife become economically and culturally important to the future of rural communities. Currently, this is not the case. Such issues are discussed in more detail in Chapters 9 and 11. A 2004 wildlife census by Donfack and Tsakam (2005) indicated a major decline in key species within Benoué National Park and hunting blocks 1 and 4, though no confidence limits were provided:

	<u>1975</u>	<u>YEARS</u>	<u>2004</u>
Number of Lord Derby Eland	375		50
Number of Buffalo	2,060		72
Elephant	-		100

5.9.3.5 Decreased fallow associated with over-population, decreased mobility and land use changes, Sangha Basin, French Equatorial Africa/Afrique Équatoriale Francaise (AEF)

Loss of mobility as a soil management tool from French colonial policies of *regroupement* into villages along roads (see Chapter 3, Section 3.1, COLONIAL STATE IN AFRICA), increasing populations, creation of concessions leased to Europeans, and eventually parks and protected areas resulted in fallows of seven to eight years being reduced to two to three years. Gaining control of the Sangha Basin following WWI, the French required villages to clear and cultivate land for 500 meters around villages to eliminate tsetse fly habitat as the result of epidemics of human sleeping sickness. Previously the average plot had been one ha. They were required to cultivate these larger areas with potatoes, peanuts, maize and soy near houses; cassava and bananas further away. The French agricultural policies at the time dictated what was cultivated and the amount of land under cultivation, but not land management practices. However, as the French vision grew of Ubangi-Shari-Chad (of which the Sangha became a part) becoming an agricultural powerhouse, larger areas of forest were cleared. Forest clearing increased following WWII, as local people were pushed into cultivating coffee and cacao. This resulted in decreased cultivation of food crops and a corresponding decline in the nutritional status of local residents. Peasant production of cash crops was resisted by private European concessionaire plantations. Slowly maize was abandoned as a primary crop in favor of less

nutritious cassava that required far less planting and weeding time than maize. Cassava also became a cash crop to feed workers employed by the administration and artificial populations associated with concessions such as logging camps. Both fallow and crop diversity declined while field sizes increased (Giles-Vernick, 2002).

5.9.3.6 East and Central Africa, loss of fallow periods

In countries with limited cultivable land and high population-growth rates - such as Kenya, Ethiopia, Malawi, Burundi and Rwanda - fallow periods are no longer sufficient to allow soil fertility to be restored, so that crop yields have fallen. In response, farmers have been forced, either to bring increasingly marginal lands into cultivation, or to migrate into tropical forest areas, exacerbating problems of land degradation and deforestation (Nana-Sinkam, 1995).

Over-population, loss of fallow, Malawi

One of the causes of degradation is that population pressure is forcing farmers to cultivate increasingly marginal land. In Malawi, for instance, escarpment land that has a slope of more than 12% - and that should therefore be forested - is being cultivated, causing erosion, the flooding of fertile crop land below, and the siltation of stream beds and irrigation canals. Thus erosion is threatening the future of one of the few countries in Africa that was successfully feeding itself (Nana-Sinkam, 1995). Malawi is no longer feeding itself (see Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife).

5.9.4 Forest Losses Linked to Over-Population, Agricultural and Land Scarcity

As discussed, human population pressures and decreasing fallow are forcing poor people to expand cultivation into marginal and fragile areas. To survive, the landless are clearing forests, eking out a living on poor quality land or moving to the cities. Barbier (1998) found a positive correlation between rural population density and forest clearance across Africa, reflecting the critical role played by rural poverty combined with population growth in land degradation and conversion processes.

Forests cover approximately 33% of the world's land area, excluding Greenland and Antarctica. Recent estimates of forest coverage indicate that up to 50% of the world's original forest cover has been destroyed, and that deforestation continues to be a problem. The two principal land uses that contribute to the degradation of forestlands are commercial logging and land conversion to agriculture (GEF, 2002). Much of the “original” closed canopy forest cover⁷⁷ in Africa that is much of the forest loss appears to be in what is today called savanna or forested savanna (see Figure 5.1: African ecosystems). The loss of closed canopy forest would have been due to both anthropogenic changes and climatic changes from the gradual drying of the continent that began around 8,000 years ago. Humans would have accelerated this process (see Chapter 1, Section 1.7, BANTU AFRICA). Based on the resource maps provided by Revenga, *et al.* (1998), it would appear that the Sahelian and Sudano-Sahelian zones along with the southern tip of the African

⁷⁷ “This percentage was calculated by dividing the extent of current forest cover in square kilometers by the extent of original forest cover in square kilometers for each basin. Current forest refers to closed canopy forest in existence today. Original forest cover refers to an estimate of the extent of closed canopy forest in existence 8,000 years ago, assuming current climate conditions” (Revenga, *et al.*, 1998).

continent have less than 25% of their original closed canopy forests remaining, while that of the Congo Basin remains relatively intact.

5.9.4.1 Current forest cover, Sub-Saharan Africa

It is estimated that in the year 2000, forests covered about 27% of Sub-Saharan Africa or about 6.3 million km² in 2000 (Figure 5.1 and Tables 5.20 and 5.21) (FAO, 2000a & FAOSTAT, 2004). This estimation includes forested savannas such as the *Acacia* spp./*Combretum* spp. woodlands of West Africa, as well as the miombo (*Brachystegia* spp.) and mopane (*Colophospermum mopane*) forests of Southern Africa (Figure 5.1). The remainder include dense humid (lowland hardwood or tropical rain) forests (Figure 5.1), afromontane forests, mangrove forests, etc. Many of these forests are only conducive to sustainable agriculture based upon tree crops such as natural hardwoods, coffee and cacao, and wildlife along with “slash and burn” agriculture with long fallow periods.

Table 5.20: Sub-Saharan Africa forest cover in 2000

Tropical Rain Forests/Dense Humid Forests

Tropical rain forests/dense humid forests in West Africa have been reduced to patches (FAO, 1995). More specifically,

“much of the West African tropical humid forests, located mainly in lowlands and accessible to the coast, have already undergone substantial commercial harvesting. In many areas, these forests have been converted to agricultural use. Nigeria and Cote d'Ivoire are cases in point. Most of the primary forests of these countries had been heavily logged by the 1970s. Expansion of agriculture onto forest lands has occurred in both countries: in the more densely populated Nigeria, clearing for subsistence agriculture has predominated, while in Cote d'Ivoire, large areas of forest have been replaced with agricultural plantation crops” (FAO 1995).

⁷⁸ Forests and Woodland: “Land under natural or planted stands of trees, whether productive or not. This category includes land from which forests have been cleared but that will be reforested in the foreseeable future, but it excludes woodland or forest used only for recreation purposes. The question of shrub land, savannah, etc. raises the same problem as in the category ‘Permanent meadows and pastures.’ In the year 1995 and onward there will be no data for this element, data relating to forest area can be obtained from the FAO Forest Resources Division...The dividing line between this category (Permanent meadows and pastures) and the category "Forests and woodland"; is rather indefinite, especially in the case of shrubs, savannah, etc., which may have been reported under either of these two categories” (FAOSTAT 2004).

Ivory Coast's 11.7 million ha (29 million acres) of forests were reduced to 1.4 million ha (3.4 million acres) by 1980 (Meredith, 2004). In 1995, only 0.46 million km² (463,240 km²/46 million ha) of "West Moist Africa" forests remained (FAO, 1995). "West African rainforests are already highly fragmented. The only large forest blocks remaining are in the border zone between Liberia and Ivory Coast. In Ghana, small remnant rainforest patches are restricted to protected areas" (WWF, 2001). "In West Africa, most of the dense humid forest has been converted to agriculture, causing a fragmentation of chimpanzee habitat" (Woods Hole, 2005).

"Except for the Congo Basin, Africa's frontier forests have largely been destroyed, primarily by loggers and by farmers clearing land for agriculture. In West Africa, nearly 90 percent of the original moist forest is gone, and what remains is heavily fragmented and degraded. Today, West African unspoiled forests are restricted to one patch in Côte d'Ivoire and another along the border between Nigeria and Cameroon" (Hennig, 2006).

Since most of the dense humid forest in West and East Africa has disappeared, this leaves about 2.0 million km² of dense humid forests primarily from the Congo Basin (Vande weghe, 2004) and about 3.8-4 million km² of savanna forests. This also assumes that the remaining afromontane forest make up less than 1% of total forest cover and have been virtually eliminated by agricultural expansion in Uganda, Kenya, Tanzania, Ethiopia, Rwanda and Burundi.

5.9.4.2 Original versus today's forest cover in Sub-Saharan Africa

The World Economic Forum (2004) depicts that Africa originally had about 6.7 million km² (670 million ha) in forest cover and today is left with about 2.1 million km² (210 million ha) or a net loss of 4.6 million km² (460 million ha). The 210 million ha forest cover for Africa compares to an estimate of 527.6 million ha in 1990 (FAO, 1993 *In: Barbier, 1998*) (Table 5.22) (appears to be

Sub-Saharan Africa plus Madagascar), 712.6 million ha in 1994 in Table 5.21 (FAOSTAT, 2004) and 649.9 million ha in 2000 (Table 5.20) (FAO, 2000a). However, the World Economic Forum estimate correlates well with the 2-2.5 million km² of dense humid forests, most of which are found in Central Africa's Congo Basin, as described by Vande weghe (2004), that remain after a combination of continental warming beginning about 8,000 years ago and the loss of dense humid forests between Cameroon and Guinea-Conakry largely depleted by humans. How does one define forest? It must be assumed that the World Economic Forum classified only closed canopy forests while ignoring the evolution of savanna forests that are included in FAO calculations.

Table 5.22: Forest cover loss in Africa, 1980–90

Geographic al Region	Number of Countries	Land Area (Million ha)	Forest Cover (Million ha)		Annual Deforestation 1980 to 1990	
			1980	1990	Million ha	% Per Annum

5.9.4.3 Deforestation in Sub-Saharan Africa's dense humid forests today compared to the Amazon of South America

In Sub-Saharan Africa's tropical lowland hardwood forests (dense humid forests) of Central Africa most commercial logging is selective with one to two trees

harvested/ha, as opposed to South America where land is being clear-cut on a large scale for farming and livestock.

Comparing Deforestation in the Congo Basin to the Amazon Basin of South America

The Amazon supports approximately 300 million ha (3 million km²) of tropical forest (dense humid forests), the largest single area of tropical forest communities in the world (Camill, 1999). From one to three million ha (10-30,000 km²/year) are being cleared annually in the Amazon Basin (Laurence, 1997 In: Camill, 1999), or 0.3-1.0% of total forest cover. Similar to West African dense humid forests that have been heavily impacted by agricultural clearing, but unlike the Congo Basin, according to Ford (2005),⁷⁹

“there has been extensive change in land use from forest to non-forest cover in the Amazonian Basin, not only in Brazil, but also in Peru, Bolivia, and Ecuador, and to some degree Colombia. This has generally been for cattle ranching and agriculture. In the case of Brazil, subsidies were given for many years to promote cattle ranching, with the result that land use change was accelerated. Brazil has also supported development of roads through the Amazon and in other states for the purpose of supporting colonization of forested areas, in part to relieve stress of population growth. Road construction is also a subsidy for change in land use”⁸⁰.

⁷⁹ Dr. Loren B. Ford. - State and Private Forestry Program Coordinator, USDA Forest Service Strategic Planning & Resource Assessment Staff, 1621 N. Kent Street, Room 602, Arlington, VA. 22209. Former USAID Caribbean Regional Forestry Advisor/Biological Scientist, U.S. Government 22209, lbford@fs.fed.us, (703) 605-4478 fax (703) 605-4199.

⁸⁰ I don't have ready access to statistics, but I'm sure that a disgracefully small percentage of the timber that is felled during conversion from forest to non-forest land use (in the Amazon) is actually put to good use for buildings or other products. The branches and smaller trunks are burned, and the larger trunks (which are too large to efficiently burn) slowly rot, with grazing and cropping carried out among the logs. Agricultural settlers use different species for specific purposes, poles and pit-sawn lumber for home and out-building construction, palms for thatch, etc. In some cases, logging concessions are granted (in all of these countries), but in the vast majority of these cases only the most valuable species are actually logged (such as mahogany, Spanish cedar, and a few other species), while poorly planned logging damages much of the

A recent study in the top five timber producing states of the Brazilian Amazon using satellite imagery indicates that selective logging adds 60⁸¹ to 123% ⁸² more forest area damage/year than has been reported for deforestation alone, while nearly doubling the amount of forest impacted by humans over a three year period

remaining forest cover. The companies granted the concessions (frequently through corruption-affected practices) seldom have a long-term interest in management under which they would benefit from better-planned logging and measures to improve the forest stand for future harvests. The roads used to extract the timber are then used by agricultural colonists, who actually carry out the conversion in land use. Without these farmers, forest would always return, although not necessary with the same distribution of species. Mining and petrochemical exploration and development also create roads, with the same effect. Workers in these extractive industries harvest game animals for personal consumption in their field camps and capture animals for illegal sale to the international pet trade, usually with an extremely high mortality of animals because of inadequate handling" (Ford, 2005.).

de Haan, et al. (1997) estimate that once forest is converted to pasture in the Amazon Basin, these pastures last no more than 10 years, their productivity being significantly reduced from loss of soils and nutrients. There are between 20 and 35 million ha of abandoned pasture in the Amazon basin (Serrao & Toledo, 1990 *In:* Cajas-Giron, Jones & Sinclair, 2002). The other major cause for deforestation is imported "slash and burn" agriculture, with three years of farming and then often abandonment, soils being similar to many of those in Sub-Saharan Africa, with "highly weathered aluminum and iron oxide clays that are acidic and deficient in plant nutrients, especially phosphorus. Tropical ecosystems are adapted to nutrient-poor soils as evidenced by the relatively large fraction of ecosystem nutrients stored in vegetation (compared to soils) and widespread plant adaptations like evergreen leaves that conserve nutrient loss (Vitousek & Sanford, 1986 *In:* Camill, 1999)...Cattle numbers decline from an average of two healthy head/ha following clearing to less than 0.3 head/ha 20 years following clearing (Serrão and Homma 1993 *In:* Camill, 1999). After just two years of grazing, some cattle exhibited 20% mortality and complete reproductive failure due to a lack of phosphorus in pasture grasses (Buschbacher, 1987 *In:* Camill, 1999)...land grabbing followed the appropriation of the Amazon frontier, leading to many bloody clashes between cattle owners and peasant farmers. A recent estimate suggested that of the 4 million residents of the Amazon, 150,000 or 4% are forcibly evicted from their land each year (Hall, 1989 *In:* Camill, 1999). From the perspective of cattle ranching, it is cheaper to appropriate pasture by the forced removal of farmers than to clear forest" (Camill, 1999). Of course, this pushes the evicted residents to clear more forests in order to survive. Logging tends to be selective, but appears to be unsustainable. Oversupplies of beef and timber from the Amazon Basin have led to price deflation and debt with banks in industrialized nations, exacerbating timber exports (Camill, 1999). Likewise, Mongabay (2005) gives an example of how devaluation of Brazil's currency, which would likely have been part of an IMF/World Bank structural adjustment program, increased exports of beef from Brazil from 40-70% between 1990 and 2001. By 2003 for the first time, growth in cattle production was largely export driven and which 80% of this came from the Amazon Basin – thus exasperating deforestation.

⁸¹ 12,075 km²/year selective logged versus 19,963 km²/year deforested from 2001-2002.

⁸² 19,823 km²/year selective logged versus 16,112 km²/year deforested 1999-2000.

from 1999-2002 from 52,253 km² for deforestation alone to 98,403 km² when selective logging is taken into account (Asner, Knapp, Broadbent, Oliveira, Keller & Silva, 2005). The environmental and social impacts of selective logging would likely be similar to those described in the Congo Basin in this chapter and in Chapter 11. The next step will be to determine how widespread this is throughout the Amazon Basin.

Retaining Structural Integrity While Losing Biodiversity in the Congo Basin From Logging

Presently, Sub-Saharan Africa's dense humid forests of Central Africa may not be as structurally endangered as in the Amazon Basin of South America but, as is discussed elsewhere, biodiversity is threatened by logging practices and the related bushmeat trade [Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas and Section 11.11.7, Case Study Bongo in the Congo (Brazzaville)]. Forest fragmentation by logging roads is a major problem, allowing easy penetration by outsiders, with the net result that bushmeat and other non-timber resources are being mined for short-term gain, even though the forest remains essentially intact. When logging roads are overlain, on the dense humid forests of the Congo Basin (Central African Republic, Congo, Democratic Republic of Congo, Cameroon, Equatorial Guinea, and Gabon) large unfragmented blocks of forest decline from 83% to 49%, with 42% of forest area in the six countries within 10 km of a road and more than 90% within 50 km of a road. "Only 7% of forest area is closer than 1 km or further than 50 km from a road" (WRI, 2000).

"In Sub-Saharan Africa, crop production, and especially the expansion of permanent plantation crops, such as oil palm and rubber, have been major causes of deforestation (in

dense humid forests). Very little tropical rainforest (dense humid forests) has been converted into ranches (e.g., as in South America) on this continent” (Sharma, Rietbergen, Heimo & Patel., 1993 *In: de Haan, et al., 1997*) (Table 5.23).

Sharma *et al.* (1993 *In: de Haan, et al., 1997*) argue that over-exploitation of forests and logging roads contribute to deforestation by allowing access by itinerant farmers. The principal author has not seen this in Southeastern Cameroon nor in adjacent Congo Brazzaville. During the colonial times, villagers were moved along the edges of the main roads, a policy known as *regroupement* (see Chapter 3, Section 3.1, COLONIAL STATE IN AFRICA and Chapter 5, Section 5.9.3.5, Decreased fallow associated with over-population, decreased mobility and land use changes, Sangha Basin, French Equatorial Africa). Most people are not going to go further from their village than would enable them to farm during the day and return by nightfall (Biko'o, *pers. comm.*).

**Table 5.23: Some estimates of the main causes of deforestation
(percent of total deforestation)**

Region	Crops	Livestock	Forest exploitation
South America	25	44 (70 in Brazil)	10
Asia	50-60	Negligible (Philippines and Indonesia to some extent)	20
Africa	70	Negligible	20

Source: Bruenig (1991 *In: de Haan, et al., 1997*) with permission, UN& FAO.

With more than half the population living in urban centers (30-80% depending on the country) and low human population densities in Central Africa's dense humid forest massif (Congo Basin) of less than two inhabitants/km², “slash and burn” agriculture still represents a danger to these forests (Vande weghe, 2004).

NASA (1996) estimates a total of dense humid forest of 1.7 million km² in Central Africa at the end of 1985, with a loss of at 350,000 ha/year from the end of 1980 until the end of 1985, basically in the Congo Basin.⁸³ The approximately 2 million km² (Vande weghe, 2004; Musa, 2006) of Central Africa's dense humid forests (Congo Basin) in 2004 are between 67-75% of what they were 8,000 years ago (2.7-3.0 million km²), and are experiencing a rate of deforestation averaging 0.35%/year (7,000 km² or 700,000 ha/year) (Vande weghe, 2004) up to 1.5 million ha/year (Musa, 2006). Nadine Laporte, of the Woods Hole Research Centre in Falmouth, Massachusetts, estimates that 30% (1.3 million ha) of the more than 3.9 million km² of the Congo Basin are being logged (Connor, 2007), while from 6% (Wilkie, Carpenter & Zhang, 2001) to 12% (Connor, 2007) are protected. This deforestation is serious but on the order of 1.4 to 4 times less than the maximum area cleared/year of Amazon Basin forests. WWF estimates that 66% of the Congo Basin could disappear (maybe better to say become degraded) within the next 50 years from logging and mineral exploration (Musa, 2006).

Interestingly enough, Vande weghe (2004) argues that given the Congo Basin's current low human densities in the dense humid forest massif, "slash and burn" agriculture may be one of the few areas in Sub-Saharan Africa that is both sustainable and good for biodiversity, creating mosaics of landscapes. Similarly, Chapter 11 (see Section 11.11.4.3, Impacts on Bwindi's natural system from excluding people) discusses the positive role man's manipulation of forests can play, creating gorilla habitat in the afromontane forests of Bwindi, Uganda. However, given today's human populations and the pressure for resources, regardless of lowland or afromontane forests, more intensive management will be required, implying controlled access, to assure sustainable exploitation of these resources. Given the dependence of rural Africans on these resources, trying to exclude them as a means of conserving biodiversity through parks and hunting

⁸³ From Cameroon, CAR, Congo Brazzaville, Equatorial Guinea, Gabon, DRC (Zaire) and Angola

blocks risks creating poverty and may result in clandestine harvesting and thus loss of an ability to manage them on a sustained yield scientific basis.

Revenga, *et al.* (1998) estimates that the Congo Basin has lost more than 1 million km² of original forest cover compared to 8,000 years ago. de Vos (1975) also estimates that closed tropical forests in Africa have shrunk by at least 100 million ha (1 million km²). In some cases, loss can also mean degraded secondary forests from “slash and burn”, charcoal production, unsustainable logging, etc. Between 8,000 and 6,000 years ago (BP) the dense humid forests of Central Africa reached their maximum area, but 2,500 to 2,000 years ago they were much less than today corresponding to a world-wide climatological phenomenon (low rainfall period) (Vande weghe, 2004) indicating an expansion and shrinking of the forests linked to climate. Given modern man’s impact on the environment (e.g., declining fallow periods, reduced soil fertility, expansion onto new lands) with populations more than doubling in 50 years, one must ask if the Congo Basin’s forests will ever expand again in the presence of man unless lifestyles change.

5.9.4.4 Population, Commercial Maize and Forest Loss in Ghana, 1908-1996

Due to concern over the loss of forest, by 1939, 1.5 million ha or 20% of the land in the moist forest zone was placed under government protection as forest reserves. Much of this conversion was due to movement away from cocoa to maize (see Chapter 12, Section 12.4.4.2, Impacts of structural adjustment on peasant production systems, Impacts of structural adjustment on central Ghana cash crop economies, fallow and virgin forests). McCann (1999) believes that the World Bank and others have made a major error in estimating a loss of 75,000 ha/year of forest since 1900, with the assumption that these forest reserves were primary forests when in fact: 1) many were secondary forests, former oil palm fields or canopy-covered cocoa estates, and 2) populations declined or dispersed

from this area in the mid-19th century leaving many formerly cultivated fields and settlements to regenerate into secondary forests (Fairhead & Leach, 1996 *In: McCann, 1999*). In 2004/2005, with the massive displacement of people from the Sahel to coastal countries and the apparent reduction in fallow across this region, is this still the case?

5.9.4.5 Deforestation in the Ivory Coast

The cost of growing cocoa, coffee, palm oil and bananas, uncontrolled logging, along with the large influx of immigrants from the Sahel has been massive deforestation. Hardwood forests, which covered 70% of the country in 1900, by 1986 had been reduced to 5% of the territory (Rosenblum & Williamson, 1987). The tropical forest area in Ghana, the Ivory Coast, Liberia, Guinea-Conakry, and Sierra Leone has been reduced originally (around the year 1900) from 313,000 km² to 87,000 km² (in the 1980s) (Parren & De Graaf, 1995 *In: Lycklama à Nijeholt, et al, 2001*) compared to an estimated 463,240 km² of “West Moist Africa” forests remaining in 1995 (FAO, 1995) that may also include forests in Guinea-Bissau, The Gambia, southern Senegal, Togo, Benin, Nigeria and southwestern Cameroon (see Section 5.9.4.1, Current forest cover, Sub-Saharan Africa).

5.9.4.6 Deforestation in afromontane forests

“To compensate for the falling yields caused by soil erosion, farmers in the highlands of Sub-Saharan Africa have cleared forests on steeper slopes, accelerating land degradation in the process. With population growing at around 3% a year, and the population density in some of the most vulnerable rural areas increasing even faster, the dangers posed by this cycle of increasing poverty, deforestation, and accelerating land degradation are readily apparent” (Nana-Sinkam, 1995).

The afromontane forests [e.g., Rwanda, Burundi, eastern DRC and western Uganda (Albertine Rift); Tanzania, Kenya, Ethiopia, and the highlands of Cameroon] are also being impacted by agricultural expansion. However, much of this deforestation occurred prior to the arrival of the Europeans (see Chapter 2, Section 2.3.4.2, Traditional irrigated agriculture). By the time the first Europeans arrived in Rwanda and Burundi, 90% of the forests were already gone, while in the highlands of Cameroon (e.g., Bamileke Plateau and Adamoua Plateau) grass fields had largely replaced forests 2,000 to 3,000 years ago (BP) (1,000 BC to 0 A.D.), one of the reasons for the Bantu migrations (Chapter 1, Section 1.7, BANTU AFRICA). Today in the uplands of Rwanda, Burundi and Uganda no more than 5% of the original forest cover remains and no tract exceeds 100,000 ha, yet they manage to preserve 90% of the original biodiversity (Vande weghe, 2004).

Over-Population, Land Degradation and Hunger Linked to Deforestation for Agriculture in the Highlands of East Africa

“Kenya has 8.5% of its original forest cover, Tanzania between 22-43% (depending on whether miombo woodland is included), and Uganda 7.2%. The countries continue to lose their forest cover at a rate of 1.7% per annum (Kenya), 1.3% for Uganda, and 0.3% for Tanzania (FAO, 1997c *In:* Barrow, *et al.*, 2000). As human populations in high potential agriculture areas grow, the frontiers of cultivation have been pushed into forests, river valleys, and semi-arid areas” (Barrow, *et al.*, 2000).

For instance, in 1998, a total of 113,400 people lived in 54 villages of the East Usambara Mountains of Tanzania. Since the 19th century, over 50% of the forest of the East Usambara Mountains has been cleared for commercial crops (coffee and tea), commercial and individual logging, forestry plantations and agriculture. Fragmentation has resulted in just eight major patches of forest remaining (Roe, Mulliken, Milledge, Mremi, Mosha, & Grieg-Gran, 2002). If the reader goes

back to Chapter 2, it becomes evident that many of the Tanzanian highlands were already suffering from over-population in pre-colonial times.

Deforestation in the Ethiopian Highlands

Due to the farming of steep slopes, it is estimated that the Ethiopian Highlands lose 62 tons/ha/year (25 tons/acre/year) of top soil. Since 1900, it is estimated that forest cover has decreased from 50% of the highlands to just 3% (Rosenblum & Williamson, 1987), jeopardizing such unique species as the mountain nyala (*Tragelaphus buxtoni*) and the simian fox (*Canis [Simenia] simensis*).

Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Fuelwood Spawning Political Destabilization

“In 1950, Rwanda’s population was 1.9 million. By 1994, it was nearly 8 million, making it the most densely populated country in Africa. As populations grew, so did the demand for firewood. By 1989, almost half of Rwanda’s cultivated land was on slopes of 10 to 35 degrees, land that is universally considered uncultivable. By 1991, the (fuelwood) demand was more than double the sustainable yield of local forests. As a result, trees disappeared, forcing people to use straw and other crop residues for cooking fuel. With less organic matter in the soil, land fertility declined” (Brown, 2003a).

Mair (1977) came to similar conclusions, namely that

“one reason for the revolution in Rwanda seems to be that the Hutu were short of land for cultivation because so much was taken for grazing of Tusi (Tutsi) cattle. It may be that Tusi have suffered less than the peoples of Uganda from epidemics of rinderpest which have decimated the herds from time to time”.

Ninety-five percent (95%) of the land was under cultivation with the average family of eight living as subsistence farmers on less than 0.02 ha (0.05 acres) (Gourevitch, 1998).

“As the health of the land deteriorated, so did that of the people dependent on it. Eventually there was simply not enough food to go around. A quiet desperation developed among the people. Like a drought-afflicted countryside, it could be ignited with a single match. That match was the crash of a plane on April 6, 1994, shot down as it approached the capital of Kigali, killing President Juvénal Habyarimana. The crash unleashed an organized attack by Hutus, leading to an estimated 800,000 deaths, mostly of Tutsis. In the villages, whole families were slaughtered lest there be survivors to claim the family plot of land. Deaths were concentrated in communities where caloric intake was the lowest” (Brown, 2003a).

Population pressure contributed to the tensions and the slaughter, although it was by no means the only factor (Brown, 2003a). Gasana (2002, *In: Matthew, Halle & Switzer, 2002*) goes into great detail in explaining how population pressures and environmental scarcities (e.g., land and firewood) combined with drought, famine and civil war fueled the 1994 genocide. As Rwanda’s population increased, inherited land became increasingly fragmented as each generation subdivided that which was passed on from the previous generation to the point that a family landholding was incapable of supporting a family unit (husband, wife and children), resulting in near-landless or landless farmers. Based on a 1984 survey (Gasana, 2002 *In: Matthew, et. al., 2002*):

- 43% of the poorer families, *abakene*, owned only 15% of the cultivated land, averaging 0.25-0.75 ha/family;
- 50% of rural families had to rent land to meet subsistence needs;
- 16% of “*land-rich*” families, *abakire*, owned 40% of the cultivated land, a family landholding averaging 1 ha; and

- By 1989, 50% of the cultivated soils were on slopes greater than 18% that experienced continual soil erosion and thus decreasing production. The other movement was movement onto good pasture lands that became marginal agricultural lands, reducing available grazing lands from 34% of the territory in 1965 to 16% by 1987, increasing livestock densities and over-grazing on the remaining pasture. These *abatindi* were basically landless, with no education skills or jobs, and were pushed to cultivating marginal, rocky and often acidic soils, best managed as natural forest or cultivated in tea, as opposed to intensive cropping. Similar to the *tapades* in Guinea-Conakry (Section 5.9.3.2, Loss of fallow turning wildlife into a short-term resource, Fouta Djallon Mountains, Guinea-Conakry), only highly manured gardens around the homesteads were productive.

By 1984, approximately 15% of the land-owners owned half of the land, tending to be urban elite in commerce, government, or the aid industry, rather than full-time agriculture. By 1990, 25% of the rural population was landless, increasing to 50% in some districts. Also land was/is highly fragmented, the average Rwandan household possessing 5 plots, increasing to as many as 10 plots/household in Ruhengeri (Musahara & Huggins, 2005 *In: ACTS*, 2005).

As a result, 66% of the population was unable to meet the minimum energy requirements of 2,100 calories/person/day⁸⁴ and rural unemployment among adults reached 30%. This unequal access to the best land had been linked to political power and nepotism since the 1970s. These political elites, both Hutu and Tutsi, known as *abary* (*eaters*) initially caused the issue to be seen as rich versus poor, along with an agriculturally richer north/agriculturally poorer south highlands divide, and not Hutu versus Tutsi. These elites even used poverty as a resource, capturing foreign aid and directing it to their region and/or putting

⁸⁴ Other references use from 1,730-1,900 calories/person/day or less as indicating undernourishment in Sub-Saharan Africa

people from their group in charge (Gasana, 2002 *In: Matthew, et. al., 2002*). All of this was compounded by a shortage of firewood resulting in an estimated 8,000 ha (80 km²) of forest/year disappearing, which in turn forced farmers to use crop residues for fuelwood resulting in a loss of 1.7 tons of organic matter/ha/year. This greatly contributed to the loss of soil fertility, an equivalent loss of 65,000 tons/year of cereals (Gasana, 2002 *In: Matthew, et. al., 2002*).

By 1994, with a population of 7.5 million people, there were 290 inhabitants/km² and 843 inhabitants/km² of arable land (11,250 km² or 43% of the territory) (Gasana, 2002 *In: Matthew, et. al., 2002*). In 2005, there are 350 inhabitants/km² (Musahara & Huggins, 2005 *In: ACTS, 2005*). Diamond (2005a) places Rwanda's population density at 293/km² (760/mi²), higher than the United Kingdom of 236 inhabitants/km² and approaching that of Holland at 367 inhabitants/km².

A big difference between Rwanda and the United Kingdom/Holland is that most of Rwanda's population lives a rural subsistence lifestyle, while those of the United Kingdom and Holland are highly urbanized and industrialized. The biophysical carrying capacity of Rwanda was estimated at 5,240,000 people with 2,360,000 of its nearly 8 million people living in a situation of permanent food insecurity. This was resulting in reduced fallow and people moving up mountainous slopes on increasingly marginal land (Gasana, 2002 *In: Matthew, et. al., 2002 & Musahara & Huggins, 2005 In: ACTS, 2005*). "The resulting degradation of the ecological capital forced rural inhabitants into a vicious cycle of poverty" and thus caused friction between the haves and have-nots (Gasana, 2002 *In: Matthew, et. al., 2002*). Diamond (2005a) estimates that all arable land outside national parks was being cultivated, the entire country looking like a garden and banana plantation, with little or no soil conservation measures being implemented (e.g., terracing, plowing along contour lines instead of straight up

and down, fallow cover vegetation between fields instead of bare fields). Farmers could wake up in the morning and find their entire field of top soil and crops washed away or their neighbors field and rocks being washed down on their fields. Deforestation resulted in water-holding capacity declining and streams drying up.

“Given the current major problem of land scarcity in Rwanda, strong and urgent programs for population growth control, off-farm activities, and agriculture intensification should be introduced, nationwide, so that even the elite can learn to look for other opportunities of gaining wealth other than just grabbing and purchasing land” Kairaba-Kyambadde, 2005 *In: ACTS, 2005*).

The 2001 Poverty Reduction Strategy Paper (PRSP) addresses the land issue recommending 1) households consolidate plots so each holding is not less than 1 ha, 2) ceiling of 50 ha on land ownership, 3) all land registered to improve tenure security; 4) land titles tradable, but not in a way that fragments plots below 1 ha, and 5) communities involved in the process of allocating title (Musahara & Huggins, 2005 *In: ACTS, 2005*).

How the political elite used resource scarcity, poverty and unemployment to fuel the Rwandan genocide, which in turn played into the geopolitical power struggle between France and the United States, is discussed in Chapter 13, Section 13.8.6, Former Cold War allies vying for power in the Great Lakes Region.

Neighboring Kivu Province, DRC

This province was mainly settled by Tutsi and Hutu collectively called Banyarwanda, who arrived before the colonial era (Gasana, 2002 *In: Matthew, et. al., 2002*). Prior to colonialism, land was regulated by a hierarchical administration based on communal territorial ownership. The Belgian colonial

power pushed indigenous systems of land tenure into a new regime of customary law that “containerized” the local population. This involved the “rigidification” and in some cases a re-definition of ethnic identities and a codification of customs in addition to creating a double system of property rights; customary for local people and a modern system of private ownership by white settlers that enabled them to establish their plantations, through application to the central state. “Vacant land” was declared the property of the colonial state and expropriated for settler-owned concessions with compensation being paid to the customary leaders (*mwami*), rather than to the people. By about 1910, colonialism defined and accentuated differences between ethnic groups and their rights of access to land (e.g., Kinyarwanda speaking people considered indigenous and given customary authority over land, disputed by Banyarwanda immigrants that were mainly of Tutsi-origin (Vlassenroot & Huggins, 2005 *In: ACTS*, 2005).

Even prior to the 1994 exodus, this province was fertile but densely populated. By the end of the 1980s, 49% of the population in Kivu lived in areas with a density higher than 100 people/km², this density of people covering no more than 13.4% of DRC’s territory as a whole (Vlassenroot & Huggins, 2005 *In: ACTS*, 2005). Land tenure was a major issue.

The land rich and politically powerful Banyarwanda were pitted against an alliance of Hunde, Nande and Nyanga ethnic groups. Vlassenroot & Huggins (2005 *In: ACTS*, 2005) attribute this problem to conflict between customary law and modern law based upon individual ownership introduced in 1973 by the independent Zairian state (today’s DRC). Banyarwanda, who had purchased land with a title deed from traditional authorities refused to pay tribute to Hunde chiefs for the use of the land, while customary rules no longer had legal status. Meanwhile the average peasant became insecure over his rights of access to customary land. In North Kivu, poor Hutu farmers from Masisi had lost their land

from sale by local customary chiefs to rural capitalists of Banyarwanda origin (Vlassenroot & Huggins, 2005 *In: ACTS*, 2005). By 1993, inequitable land distribution led to ethnic clashes targeting the Banyarwanda resulting in more than 6,000 deaths and the displacement of 250,000 people (Gasana, 2002 *In: Matthew, et. al.*, 2002).

When the Rwandan Patriotic Front (RPF) of Paul Kagame defeated the Rwandese Armed Forces/*Forces Armées Rwandaises* (RAF/FAR) on July 19, 1994, 2 million Hutu refugees fled to neighboring countries; between 1.2 million (Gasana, 2002 *In: Matthew, et. al.*, 2002) and 1.5 million (Chrétien, 2003) Hutu fleeing to northern Kivu Province, DRC.

The 1994 Hutu refugees allied themselves against the Banyarwanda Tutsi. Eventually the Hunde feared this massive number of Hutu could result in their taking political control and in the creation of a Hutu state. Competition for political influence in Kinshasa fomented animosity between indigenous groups and the Banyarwanda, resulting in thousands of deaths and the displacement of 200,000 people. Eventually under Laurent Kabil, there was a new reshuffling of alliances between the Hunde, Nande, Nyanga and Hutu, forcing the Tutsi to flee to the town of Goma and to Rwanda (see Chapter 13, Section 13.8.6.9, the French connection). More recently, land disputes developed between pastoralist Hema and Lendu peasants. Land resource conflicts in the eastern DRC, help sustain conflict in the region (Gasana, 2002 *In: Matthew, et. al.*, 2002). Conflict rages on in the southern Kivu Province and will likely not cease anytime soon.

There are four lessons that can be learned from this tragic chapter in Africa's history:

- 1) "rapid population growth is the major driving force behind the vicious circle of environmental scarcities and rural poverty (and

conflict), 2) conserving the environment is essential for long-term poverty reduction, 3) to break the links between environmental scarcities and conflict, win-win solutions—providing all sociological groups with access to natural resources—are essential, and 4) preventing conflicts of the kind that ravaged Rwanda in 1994 will require a rethinking of what national security really means” (Brown, 2003a).

These same four points are also made in Gasana (2002 *In: Matthew, et. al.*, 2002). The authors believe that a combination of introducing modern intensive farming and soil conservation measures combined with alternative livelihoods mainly in urban centers as a means of taking pressure off the land and resource base are keys to future stability and food security in Sub-Saharan Africa. Meanwhile, what little forest is left, will continue to disappear at an accelerated pace.

5.9.4.7 Deforestation in savanna environments

One must first get a hand on what is savanna. By the above calculations (Section 5.9.4.1, Current forest cover, Sub-Saharan Africa), only 17-18% of Sub-Saharan Africa would be savanna,⁸⁵ compared to the 70-75% figure that is typically used. One major problem is defining forest, for example including or discounting secondary bush from fallow agriculture or various forested savannas. Estimates vary widely on the loss of forest cover in Sub-Saharan Africa, depending on what is classified as a forest. For instance, depending on whether forested savanna is classified as forest or savanna can account for these wide variations in estimates of forest cover.

⁸⁵ If the majority of dense humid forest cover remaining is in the Congo Basin, amounting to about 2 million km², and the amount of afromontane (largely lost to agriculture) and coastal forests (e.g., mangrove) is insignificant then about 4 million km² of forest remain which would be classified as savanna, this making up about 18% (≈ 4 million km² of savanna $\div \approx 22$ million km² of land mass in Sub-Saharan Africa) of the land cover in Sub-Saharan Africa.

FAO, for example, takes into account savanna forests in its definition of forest

“a land area of more than 0.5 ha, with a tree canopy cover of more than 10%, which is not primarily under agricultural or other specific non-forest land use. In the case of young forests or regions where tree growth is climatically suppressed, the trees should be capable of reaching a height of 5 m *in situ*, and of meeting the canopy cover requirement” (CBD, 2004).

Whereas, Scholes, 1997 *In: Cowling, et al.*, 1997 define savannas as having tree cover from 5-90%. For this reason, one obtains widely varying estimates of savanna in Sub-Saharan Africa from 33% (Martin & O’Meara, 1995) to 75% Child (1995; 2004b both *In: Child, 2004a*) of the landmass. Today a large portion of the “savanna” environment/biome is under agricultural production and/or in fallow, with fallow on the decline. Where fallow occurs, it would revert to bush and could easily be classified as savannah habitat. Nevertheless, savannah, in the broadest sense when using the term 70-75% would have to include land in savannah and land in agriculture that would otherwise be a savannah environment were it not for man’s interventions. The savannah environment/biome might best be delimited by rainfall, below which intensive agriculture is not viable, somewhere between 30° North and South (a line across Africa from about Durban to Cairo) where annual rainfall is somewhere below 800 mm (Dumont, 1966) to below 700 mm (Bond, *et al.*, 2004 *In: Child, 2004*), but greater than 200 mm (see Chapter 1, Figure 1.3: The Sahel). Even some desert environments (rainfall below 200 mm/year) might be considered savanna depending on tree cover (see Section 5.1, INTRODUCTION).

It is believed that the majority of deforestation today is thus taking place in Africa’s savanna areas. With increasing human populations in Sub-Saharan Africa and greatly reduced and/or disappearing fallow periods, much of the deforestation in Sub-Saharan Africa can be attributed to agriculture, i.e., from expansion of

farmers into more and more marginal areas and to decreasing secondary forests that in the past came from fallow lands and served as a source of energy and other resources (e.g. honey, bushmeat, medicine) for rural people.

The destruction of forests, especially forested savannas is exacerbated as fallow disappears and urban demand for charcoal increases. Once cut over, today these areas rarely return to forests, and are permanently converted into farm and grazing land (Figure 5.10) (see Section 5.9.4.7, Deforestation in savanna environments - Deforestation in Senegal linked to charcoal making, over-population and declining fallow periods). “Asia and Africa together consume more than three-quarters (75%) of global fuelwood, mostly in domestic cooking, though cottage industries such as food drying and brick-making also consume large volumes in some countries” (FAO, 2002a). Although Africans consume 30 times less energy than North Americans do, an estimated 67% of Sub-Saharan Africa’s energy consumption depends upon traditional biomass (e.g., firewood, charcoal, manure, crop residue). Linked to clearing for agricultural purposes, deforestation is a major cause of environmental degradation such as soil erosion, floods and general habitat/environmental degradation (Davidson, Halsnaes, Hug, Kok, Metz, Sokona & Verhagen, 2003).

Loss of Forest Land in Zimbabwe from Inequitable Land Distribution and Resulting Population Pressures, the Case of Matabeleland North Province

The history of colonialization is the inequitable distribution of land between Africans and European settlers. Increased human populations, the resulting land hunger and these events as the basis for and leading to the 1970s liberation war in Zimbabwe are discussed in Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife. As noted, communal lands tend to be located in the lowest rainfall areas with the poorest

soils for agriculture, Regions IV and V where 75% of the communal lands are located. In comparison, 55% of the white commercial farms are found in Regions I and III with good soils and rainfall (Hill & Katarere 2002 *In: Matthew, et al.*, 2002). Meredith (2002) places 66% of the white commercial farms in Regions I and II, and 72.2% of the communal lands in Regions III and IV. While Wels (2000) places 75 and 66%, respectively of the land in Regions I and II in white commercial farm, and 74.2% of the communal lands in Regions III and IV, prior to radical land reform.

Inequitable land distribution forced people in communal areas to subsist through over-exploitation of resources, leading to resource degradation and livelihood insecurity. Hill and Katarere (2002 *In: Matthew, et al.*, 2002) discuss how these factors have contributed to pressure on communities to clear woodlands for short-term food production. The primary cause of deforestation in Zimbabwe is clearing land for agriculture (World Bank, 1991 *In: Hill & Katarere*, 2002). State forests were first established in 1936 and then expanded in 1941. The 1970s civil war resulted in a complete breakdown in forest administration, furthering resource depletion and illegal settlements in both forests and under-utilized commercial farms.

Even with the newly founded independence, local people were officially excluded from the forests, as opposed to being integrated into their management. Additionally, the black urban elite sought grazing leases and timber concessions in the state forests. By 1987, when the government and the Ndebele ended hostilities, the Forestry Commission attempted to re-establish management of the forests, but was unable to stem the inflow of settlers. The Forestry Commission was expected to break the white monopoly on hunting and tourism in the area, but instead has come to be seen as an extension of oppressive central government and therefore not trustworthy. Today, what had started as a national conflict against

colonial powers has turned into a conflict based on ideological and political differences, raising concerns about future economic, social and political relations between the minority Ndebele and the ruling Shona majority. Thus, the conflicts around the forest reserves have come to symbolize a broader struggle by the Ndebele against the establishment. Any attempt to evict people from the forests or to stop them from using forest resources is now seen as a direct challenge to legitimate claims by the Ndebele to use “their” resources. Forestry officials have dealt with this very complex socio-political issue purely in a legal and technical sense (Hill & Katarere 2002 *In: Matthew, et al.*, 2002), and appear to have failed to integrate the local people into the management of the area. Thus, the conflict continues and forest resources appear to be harvested in an unmanaged “open-access” manner, which risks to see them degraded in a very short time, if not disappear under the plough!

Deforestation in Senegal Linked to Charcoal Making, Over-Population and Declining Fallow Periods

During the Cold War, both the Americans and the French allegedly paid funds directly to the Government of Senegal to help cover the salaries of *functionaries* as well as to subsidize peanuts. This created the façade of a vibrant economy. Living off donor handouts allowed elites to mine Senegal’s forest resources for short-term economic gain. Local communities had been alienated since colonial times with the creation of off limits classified forests (*forêts classés*) that were still being enforced under a “fences and fines” philosophy 20 odd years after independence.

In many areas, farmers turned their backs on what they perceived as a “government’s problem” as illegal Guinean charcoal cutters clear-cut the interior of government “classified forests” while leaving a perimeter of trees untouched so

that such activities would go undetected by the understaffed *Eaux et Forêts* (forest and game department).

While local people were told that the forests were off limits, poorly paid employees from understaffed and inefficient *Eaux et Forêts*, for a cut of the action, gave cutting permits to influential businessmen, politicians or religious leaders to clear the very forests that were off-limits to local communities (see Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal). Many of these charcoal cutters began their careers in the Ferlo of central Senegal and at the time of the study, in the mid-1980s, were near the Gambian border south of Tambacounda. They were often linked to politically connected outsiders who obtained legal cutting permits.

It was estimated that 20,000 ha/year were being clear cut for charcoal⁸⁶ in the Gambia River Basin along the Koungheul/Koussanar/Tambacounda/Velingara transect with little attempt at reforestation or natural forest management (Ribot, *pers. comm. In: DeGeorges, 1987*).

Most of this charcoal was destined for the urban centers. Attempts to get people to switch from charcoal to natural gas for cooking generally failed, especially for making *thé Senegalais* the local “Chinese Gunpowder Green” tea that people believed only tasted good cooked over charcoal. Charcoal permitted them to spend hours making the tea, as opposed to gas which would be quicker but more expensive⁸⁷ and which people believed made the tea less palatable. Drinking tea is all about conversation and philosophical discussions, an important part of the

⁸⁶ Diamond (2005a) estimates a 4 to 1 ratio by weight in conversion of wood to charcoal.

⁸⁷ It can take hours to drink three cups of tea, the goal being dialogue as much as drinking. This would require enormous amounts of gas over two to three hours.

Senegalese oral culture, which cannot be ignored in getting them to adopt technologies.

Once an area was cut, small-scale farmers and livestock moved in, which meant the end of the bush. This can be linked to increased human populations and the loss of fallow pushing people into marginal areas. Hunting in these forests was common, with no one having a license. Sadly, these dry savanna forests could have been sustainably managed through rotational management and coppicing (see Chapter 9, Section 9.8.9.2, Communal natural forest management, Guesselbodi, Niger and 9.8.9.3, Community based natural forest management, “*Gestion des Terroirs*”, Burkina Faso).

An endless cycle of conflict is also being created as farmers use agricultural residue for fuel. This residue is thus no longer available as fodder for livestock in the dry season that in turn would help fertilize the land in the form of green or cow manure. Likewise, with decreasing fallow, farmers are moving onto rainy and dry season grazing areas of pastoralists resulting in a band of friction across much of the Sub-Saharan Africa as these two lifestyles collide, especially along the Sahel from Senegal to Darfur in Sudan (see Section 5.11, CONFLICT LINKED TO OVER-POPULATION AND DESERTIFICATION – SCARCE RESOURCES). Therefore, just about all causes of soil degradation and deforestation (Table 5.7) can be linked to traditional agricultural practices that are no longer viable at the beginning of the 21st century.

5.9.4.8 Carbon dioxide production and sink linked to Sub-Saharan African forests

Meanwhile, the release of carbon dioxide (CO₂) into the atmosphere from burning fuelwood and charcoal, the major source of energy for most Africans, contributes

to global warming and contributes to an important loss of biodiversity (Reich, *et al.*, 2001). However, globally, the African continent contributes less than 7% to green house gases and only about 4% to carbon dioxide emissions (Davidson, *et al.*, 2003), the onus for such pollution being on the shoulders of the industrialized West and Southeast Asia. On the contrary, it is believed that Central Africa's dense humid forests covering approximately 2 million km² provide a major carbon sink to absorb CO₂ produced by the industrialized world. While it is estimated that a hectare of tropical forest is worth US\$ 50/year through wood exploitation that may not be sustainable, it is valued at US\$ 600 to 4,400/ha/year in carbon storage. The density of carbon accumulated above the ground in old tropical forests is on the order of 120 tons/ha, reaching only half that in temporal and boreal forests (Vande weghe, 2004).

5.9.4.9 Total annual forest loss, Sub-Saharan Africa in recent times

In recent times, although estimates on annual forest cover loss in Africa vary, all agree that the loss is in the millions of ha/year. Nan-Sinkam (1995) estimates that Africa loses an estimated 5 million ha/year of tropical forest. Reich, *et. al.* (2001) estimate forest consumption in Africa to be at about 3 million ha/year. Gruhn, *et al.* (2000) estimate that in Sub-Saharan Africa, between 1973 and 1988, forest and woodland area fell by 40 million ha or 2.7 million ha/year. FAOSTAT (2004) in Table 5.21 estimates that over a 33 year period, from 1961-94, about 775,242 ha/year of forest lost, increasing to 1.2 million ha/year of forest loss in Sub-Saharan Africa over the 13 year period from 1981-1994. The FAO (1993 *In:* Barbier, 1998) estimates a loss of 4.1 million ha/year between 1980 and 1990, mainly the result of land conversion associated with agricultural expansion (Table 5.22), 99% from Sub-Saharan Africa. Most agricultural expansion is believed to be happening in the savannas of Sub-Saharan Africa. Similar estimates are provided by GESAMP and ACOPS (2001). The loss of forest cover increased to

5.3 million ha/year by 2002, one must assume 99% from Sub-Saharan Africa, since the rest of the continent and insular Africa has little forest cover by comparison (FAO, 2002a). Any discrepancies come back to defining a forest since FAO (Table 5.21) admits that there is much overlap between what one calls forest and woodland versus permanent meadow and pasture. Because of this overlap and confusion, FAOSTAT stopped publishing forest and woodland cover data after 1995 referring interested parties to the FAO Forest Resources Division (FAOSTAT, 2004).

If one looks at a breakdown of deforestation in Table 5.22, where there is an estimated 4 million ha/year ($40,000 \text{ km}^2$) of forest lost on the mainland of Sub-Saharan Africa from 1981-1990, it can be deducted that about 1.1 million ha ($11,000 \text{ km}^2$)/year of forest is being lost in Central Africa, the majority in the Congo Basin (Gabon, DRC, Congo Brazzaville, Cameroon and the Central African Republic), and about 2.8 million ha ($28,000 \text{ km}^2$)/year in the remainder of the mainland of Sub-Saharan Africa, the majority of which would be forested savanna. If one takes Vande wege's (2004) current estimate today of 7,000 km^2/year low dense humid forest loss in the Congo Basin as being accurate, then another 4,000 km^2/year from deforestation of savannas is occurring in northern DRC, northern and extreme northern Cameroon, and much of the Central African Republic – that form a portion of the Congo Basin drainage. This can be added to the estimate of deforestation in Sub-Saharan Africa's savannas. Thus one obtains about 7,000 km^2/year (18% of total annual forest losses) in the dense humid forests, mainly in the Congo Basin, and 32,000 km^2/year ($28,000 + 4,000$) of deforestation in the savannas (82% of total annual forest losses), or about 4.4 times as much deforestation in the savannas as in the dense humid forests. This increased to 5.3 million ha/year ($53,000 \text{ km}^2/\text{year}$) by 2002 (FAO, 2002a), which using the above noted percentages would respectively amount to 9,540 km^2/year cleared of dense humid forests and 43,460 km^2/year of savanna woodlands. As

noted, today, west of Cameroon, low dense humid forests appear limited by comparison, while in East Africa, afromontane forests are limited to near the mountain peaks mainly in the form of parks bordered by small-scale farmers. Though significant with regards to biodiversity, factoring in the annual loss of these latter forests would modify the above estimate, but only in a minor way.

There are those who would disagree with these figures stating that secondary forests associated with fallow agricultural lands help maintain forest cover (Fairhead & Leach, 1996 *In: McCann, 1999*). The facts as we have seen them are that secondarily forested fallow lands are disappearing as per capita land for agriculture declines and fallow periods disappear. Thus, the opportunity for a continual production of secondary forest from fallow lands is rapidly disappearing over most of Sub-Saharan Africa.

5.10 CIVIL WARS - A MAJOR CAUSE OF DECLINING AGRICULTURAL PRODUCTION AND FAMINE IN SUB-SAHARAN AFRICA

Sub-Saharan African famines have evolved from being triggered mainly by drought to primarily being caused by civil war, often “resource wars”, (FAO, 2003c; FAO, 2005) (Table 5.24). From 1997-99, 30 developing countries had average per capita food consumption of below 2,200 kcal per day (FAO, 2002a).

“War and civil strife were significant factors in no less than half of these countries. In most of them, food consumption today stands at levels below those attained in the past. Some 23 of the 30 are in Sub-Saharan Africa, while only 7 are in other regions” (FAO, 2002a). “Repeated food emergencies are concentrated in Sub-Saharan Africa, where the majority of the affected countries (61%) are hosts to civil wars” (FAO, 2005).

Although famine early warning systems are important (Eicher, 1990 *In: Eicher & Staatz, 1990*), it would seem that in most cases, one can look at a map of civil wars and near civil wars (e.g., Zimbabwe) and determine where the major food emphasis is needed in Africa.

Table 5.24: Sub-Saharan African countries facing food emergencies at the beginning of the 21st century

SUB-SAHARAN AFRICAN COUNTRIES FACING FOOD EMERGENCIES: (Total: 23 countries)

COUNTRY	REASONS FOR EMERGENCY
Angola	Returnees, IDPs
Burundi	Civil strife, IDPs
Cape Verde	Drought
Central African Republic	Civil strife, IDPs
Congo, Democratic Republic of	Civil strife, IDPs, refugees
Congo, Republic of (Brazzaville)	Civil strife, IDPs
Côte d'Ivoire (Ivory Coast)	Civil strife, IDPs
Eritrea	Drought, IDPs, returnees
Ethiopia	Drought, IDPs
Guinea-Conakry	IDPs and refugees
Kenya	Drought in parts
Lesotho	Adverse weather in parts
Liberia	Civil strife, IDPs
Madagascar	Drought in parts, economic disruption
Mauritania	Drought
Mozambique	Drought in southern parts
Sierra Leone	Civil strife, IDPs
Somalia	Civil strife, drought in parts
Sudan	Civil strife, drought in parts
Swaziland	Drought in parts
Tanzania	Drought in parts, refugees
Uganda	Civil strife, IDPs, drought in parts
Zimbabwe	Drought, economic disruption

Note: Internally Displaced Persons (IDPs), while refugees are from neighboring countries and "returnees" are returned refugees or IDPs.

Source: FAO (2003c), with permission, UN& FAO.

Poverty, environmental degradation and economic stagnation are often the symptoms that seem to breed civil war, while in turn civil wars cause poverty and economic decline. The poorest 16% (1/6th) of humanity endures 80% (4/5^{ths}) of

the world's civil wars. In 1999 in Sub-Saharan Africa, one in five (20%) people lived in a country racked by civil or cross-border wars. About 90% of the casualties were civilians, 19 million people were displaced, and 20 million landmines were waiting to take out an unsuspecting person or animal (Guest, 2004).

Based on statistics from the UN and the U.S. Committee for Refugees, in November 2000, world-wide 23.5 million people were in need of humanitarian assistance due to conflict of which 18.5 million (79%) were in Angola, Burundi, Congo (Brazzaville), DRC, Guinea-Conakry, and Côte d'Ivoire (refugees and Internally Displaced Persons/IDPs), Eritrea, Ethiopia, Kenya (refugees), Liberia, Rwanda, Sierra Leone, Somalia, Sudan, Tanzania (refugees), Uganda and Zambia (refugees). Women and children make up 70–80% of the refugees and Internally Displaced Persons (IDPs) uprooted by violence (Messer & Cohen, 2001). "There are 13 million Internally Displaced Persons (IDPs) and 3.5 million refugees, more than twice the absolute number in Asia, which has 5 times the population of Africa" (Commission for Africa, 2005).

Of 15 UN peacekeeping missions around the world, five are based in Africa: United Nations Mission in Liberia (UNMIL), United Nations Mission to the Democratic Republic of Congo/*Mission de l'Organisation des Nations Unies en République Démocratique du Congo* (MONUC) - the Great Lakes), United Nations Mission in Ethiopia and Eritrea (UNMEE), United Nations Mission In Sierra Leone (UNAMSIL) and United Nations Mission for the Organization of a Referendum to the Western Sahara/*Mission des Nations Unies Pour l'Organisation d'un référendum au Sahara Occidental* (MINURSO). Out of 48,590 soldiers and police officers under UN command, nearly 75% are on the African continent, including 10,866 with MONUC, the peacekeeping mission based in the Democratic Republic of Congo (DRC). UNMIL in Liberia is set to

become the UN's largest mission in 2004, with some 15,000 peacekeepers (ICG, 2004a). In June 2004, as unrest breaks out along the DRC/Rwanda border, the DRC requested additional UN peacekeepers.

Every major famine in Sub-Saharan Africa since 1960 has been directly or indirectly influenced by civil war and political conflict with the exception of the 1968-74 famine in the Sahel, when an estimated 100,000 people died. Since the prognosis for ending civil wars in Africa in the near future is limited, Africa will have a difficult time ending famine, as is the case in Asia (Eicher, 1990 *In: Eicher & Staatz, 1990*).

Famine may not only be a by-product of war, it may also be an instrument of war (e.g., Angola, Sudan, Horn of Africa) (Roman, 2003). African countries in conflict produce 12.4% less food per capita in war years compared to production during peacetime, and for the region as a whole, Africa's food production would have been 2 to 5% higher if there were no conflicts (Mule, 2003). According to the Food and Agriculture Organization of the United Nations, in 1990–97, conflict-induced losses of agricultural output in Africa totaled US \$22 billion, a sum equivalent to 33% of the aid received by the conflict countries and far in excess of Foreign Direct Investment (FDI) flows (Messer & Cohen, 2001).

Africans solutions to democracy have yet to found. It would be naïve to think that many of the current African governments represent the majority of citizens in their countries, the elite being in cahoots with the former colonial powers, their multi-nationals and/or donors. Meanwhile, political elites, drawing upon the desperately poor and uneducated masses, use them as pawns as they vie for access to the wealth generated from the “*mining*” of the continent’s natural resources (e.g. minerals, timber, petroleum, soil, wildlife). This has resulted in civil war and conflicts and corresponding food shortages since the end of colonialism. The

drama of it all is that one of the resource richest continents in the world is among the poorest and most backwards. Why? The reasons behind much of this violence are discussed in a Chapter 13 that looks into the background of resource wars in Sub-Saharan Africa (see Section 13.5, FAILURE TO DEVELOP GOOD GOVERNANCE IN MINERAL RICH COUNTRIES and Section 13.10, RESOURCE WARS).

5.11 CONFLICT LINKED TO OVER-POPULATION AND DESERTIFICATION – SCARCE RESOURCES

“ ‘ To continue treating conflicts in Africa as purely ethnic, tribal or religious, ignoring, in the process, the growing impact of restricting or denying access to resources and the growing ecological degradation and depletion of the renewable resource base, could ultimately, lead to a distorted understanding of the real situation and consequently, limit the possibility of a genuine conflict resolution’ ” (Suliman, 1999 *In: Koch, 2004 In: Fabricius, et al., 2004*).

Bachelor (1999 *In: Koch, 2004 In: Fabricius, et al., 2004*) describes how a degraded environment can lead to political and armed conflict.

“Tension over access to land, grazing rights, water, forests, fishing stocks, and other vital resources has also played a central role in violent conflict in Africa. Conflict between herders and cultivators over access to land creates localized violence in many parts of Africa, but can also often stretch across borders and lead to larger conflicts. For example, such disputes contributed to the current violence in Darfur, Sudan. In Côte d'Ivoire, growing local tensions over land use, linked to migration and national identity, contributed to national instability. Shared water resources can lead to tensions between countries, as in the Nile Basin” (Commission for Africa, 2005)

5.11.1 Conflict Linked to Over-Population and Desertification in Sub-Saharan Africa

“Desertification occurs whenever a non-desert area starts to exhibit the characteristics of a true desert. The term was coined by the United Nations in 1977. Over the past 50 years, at the southern edge of the Sahara, an area the size of Somalia has become desert. The same fate now threatens more than 33% of the African continent. The main cause of desertification is not drought, but mismanagement of land, including over-grazing and felling of trees and brushwood for fuel” (University of Michigan, 2002). The USDA defines desertification as “land degradation in arid, semi-arid, and dry sub-humid areas resulting from various factors, including climatic variations and human activities” (Reich, *et al.*, 2001).

Reich, *et al.* (2001), using information from the soil and climate resources of Africa, made an assessment of land resource stresses on the continent. Twenty-five (25) stress classes⁸⁸ were defined and prioritized according to the severity of the constraint in terms of the effort required to correct it for agricultural use. The results of the spatial analysis using a Geographic Information System (GIS) to create a “GIS Desertification Vulnerability” map was coupled to an interpolated population density map to obtain estimates of the number of persons affected by desertification.

Desertification processes affect about 46% (Reich, *et al.*, 2001) (compared to 33% above - University of Michigan, 2002) of the 29.8 million (Reich, *et al.*, 2001) to 30.3 million km² of Africa (Clark, *et al.*, 1975). The significance of this large area

⁸⁸ Low organic matter, high soil temperature, seasonal excess water, minor root restrictions, short duration low temperatures, low structural stability, high anion exchange capacity, impeded drainage, seasonal moisture stress, high aluminum concentrations, calcareous/gypseous, nutrient leaching, low nutrient holding capacity, High P and N retention, acid sulphate, low moisture and nutrient status, low water holding capacity, high organic matter, salinity/alkalinity, shallow soils, steep lands, extended low temperatures, extended moisture stress, etc.

becomes evident when one considers that excluded from this analysis were areas that have a hyper-arid or a humid climate (Reich, *et al.*, 2001) (Figure 5.11):

- **Desert and Steep Areas, Only Suitable For Grazing.** About 42.7 - 55% ($12.7 - 16.4^{89}$ million km²) of the land, already desert, is unsuitable for any kind of sustainable agriculture apart from nomadic grazing. Though agriculture is considered unsustainable due to soil salinization, moisture restrictions, etc., 30% of Africa's population or about 200-250 million people are living on or are dependent on this land, a large portion of these people living on the desert margins of the Sahara and Kalahari regions and along rivers traversing these areas such as the Nile and the Okavango Delta.
- **Humid Areas.** Only about 11% (3.3 million km²) of the land mass is humid and by definition is excluded from desertification processes. This is not to say that the habitat could not be degraded by man's interventions.

Of the remaining land, 34-46.3% of the continent mostly in Sub-Saharan Africa, the following area was calculated as being prone to desertification; the very high area is along desert margins (Table 5.25) (Reich, *et al.*, 2001). Thus, the majority of the land and the people affected by desertification on the continent are those living in Sub-Saharan Africa (Figure 5.11).

As calculated by Reich, *et al.* (2001), if one subtracts off the two areas not considered (desert/steep slopes of 12.7-16.4 million km² and humid areas of 3.3 million km²), one would have to conclude that 68-93% of the remaining land is

⁸⁹ Reich, *et al.* (2001) use two different percentages in their report, though the lower percentage found in their Table 4 appears to possibly not include steep-sloped areas., which could account for the difference of 42.7 % in Table 4 and 55 % given in the text.

prone (moderate to very high) to desertification, using 29.8 million km² as the base for the area of the continent.⁹⁰ Most of this land is in Sub-Saharan Africa.

Table 5.25: Estimates of African land area belonging to vulnerability classes and corresponding number of impacted population

Vulnerability class	Area subject to desertification km²	%	Population affected	
			Millions	% of African pop.
Low	4,225,000	14.2	154.5	19.9
Moderate	4,741,000	15.9	196.1	25.3
High	3,213,000	10.8	134.8	17.4
Very high	1,466,000	4.9	22.4	2.9
TOTAL	13,645,000	45.8	508.2	65.5

Extracted From: Reich, *et al.* (2001) with permission, USDA & public domain.

It has been demonstrated around the world that low-input agriculture, particularly in the absence of appropriate conservation practices (e.g., fallowing), leads to degradation of the land. As African farming is essentially a low-input low-output system, land degradation is rampant and recent studies show a progressive decrease in the performance of the land. The situation is further constrained by the geometric increase in domestic animal populations (Reich, *et al.*, 2001), particularly goats (see Chapter 6, Table 6.2: Livestock numbers in Sub-Saharan Africa, 1961-2003).

Practically every country in Africa is prone to desertification, but the Sahelian countries at the southern fringe of the Sahara are particularly vulnerable. Only about 19% of Niger is non-desert and of this 17% belongs to high and very high

⁹⁰ (29.8 million km² - [12.7+3.3] million km² desert/humid) = 13.8 million km² prone to desertification; or [9.4 million km² (Moderate to Very High)/13.8 million km²] x 100= 68%, or (29.8-[16.4+3.3] = 10.1 million km² prone to desertification, 9.4/10.1 x 100 = 93%

vulnerability classes. The Mediterranean countries of North Africa have similar large areas subject to this land degradation process as do countries on the fringe of the Kalahari Desert (Reich, *et al.*, 2001). The lands with very high risk are mostly at the desert margins in the Sahel and along the eastern seaboard of Africa. There is also a large contiguous area in the DRC where the Kalahari sands have penetrated (Reich, *et al.*, 2001).

Eswaran, Reich and Beinroth (2003) undertook a study “to define and locate desertification tension zones around the world where the potential decline in land quality is so severe as to trigger a whole range of negative socioeconomic conditions that could threaten political stability, sustainability, and the general quality of life”. Tension zones result from:

- “Excessive and continuous soil erosion resulting from over and improper use of lands especially marginal and sloping lands;
- Nutrient depletion and/or soil acidification due to inadequate replenishment of nutrients or soil pollution from excessive use of organic and inorganic agro-chemicals;
- Reduced water holding capacity of soils due to reduced volume of soil and reduced organic matter content, both a consequence of erosion and reduced infiltration due to crusting and compaction;
- Salinization and water-logging from over-irrigation without adequate drainage; and
- Unavailability of water stemming from decreased supply of aquifers and drainage bodies” (Eswaran, *et al.*, 2003).

To evaluate the number of people affected, the map of vulnerability to desertification was superimposed on an interpolated population density map

developed by Tobler, Deichmann, Gottsegen and Maloy (1995 *In: Eswaran, et al.*, 2003). In a second analysis, classes of population density were superimposed on the desertification map. In a third step of the analysis, they looked at the relation of serious conflicts in countries to risk of desertification. A conflict as defined by the International Peace Research Institute (IPRI) is one where at least 1,000 deaths resulted from a war. IPRI (1999 *In: Eswaran, et al.*, 2003) has documented countries with conflicts from 1989 to 1998. The concept of desertification suggests some or all of the following negative effects and the probability of their occurrence is highest in the tension zones:

- Systematic reduction in crop performance even leading to failure in rainfed and irrigated systems;
- Reduction in land cover and biomass production in rangeland with an accompanying reduction in quality of feed for livestock;
- Reduction of available woody plants for fuel and increased distances to harvest them;
- Significant reduction in water from overland flows or aquifers and a concomitant reduction in water quality;
- Encroachment of sand and crop damage by sand-blasting and wind erosion; and
- Increased gully and sheet erosion by torrential rain;

As a consequence of some or all of these processes, there commonly occurs societal disruption due to reduction in life-support systems. A “burning belt” exists at the transition zone where nomadic desert life meets sedentary Sahelian life, a line of conflicts and wars from Mauritania to Sudan (Kloff & Pieterse, 2002) resulting from land scarcity and degradation, which is obvious from observing Figure 5.11.

It can be argued that part of the problem today in the DRC, site of Africa's first World War, has to do not only with a scramble for the DRC's wealth of resources, but also with over-populated, soil degraded, low land per capita Rwanda and Burundi needing to expand their territories in order to relieve population pressures (see Section 5.9.4.6, Deforestation in afromontane forests, Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Political Destabilization). Part of the problem in 2003/2004 in the Ivory Coast can be linked to over-population and associated desertification in countries like Burkina Faso resulting in a mass exodus south placing tremendous pressures on scarce land resources and heightening ethnic and religious tensions. This will become an increasing problem in coastal countries such as Ghana, as people flee Sahelian states incapable of feeding themselves or offering a viable lifestyle for their citizens. One would predict that Kenya and possibly Tanzania will face increasing internal conflicts over scarce land between pastoralists and small-scale farmers to an extent that could disrupt civil society.⁹¹ This is exacerbated especially in Tanzania from external pressure to maintain 40% of its territory in parks and protected areas, resulting in habitat degradation where humans and their livestock have been compressed (see Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers).

Finally, the untold ecological damage (deforestation, soil mining, poaching, and pollution) as the result of concentrating people in refugee camps flocking out of these civil wars has yet to be quantified on a continental basis, such as the 600,000 refugees in northwest Tanzania in 1994 as a result of the Rwanda crisis.

⁹¹ (see Chapter 3, Section 3.6, THE END OF COLONIALISM AND THE ACCELERATION IN PHYSICAL SEPARATION OF AFRICANS FROM THEIR RESOURCES, Section 3.6.1, Separation of Maasai From Ngorongoro Crater, Section 3.8.4, Land Compression and the Maasai of Kenya and Tanzania, Section 3.8.5, Land Compression, Wakamba and the Black Rhino of Machakos Kenya, Section 3.11.1, Population, Kikuyu and the Mau Mau and Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya.

This is believed to have resulted in massive deforestation for firewood and poaching for food.

5.11.2 Over-population, Desertification and Instability, Nigeria

Although the differences between the Moslem north and Christian south were reinforced by Britain's "divide and rule" policy (see Chapter 3, Section 3.1, COLONIAL STATE IN AFRICA) today population pressures over scarce resources exasperate these problems.

"Many other countries in Africa face a similar situation, including Nigeria, the continent's largest most populous country with 121 million people. President Olusegun Obasanjo is trying desperately in his strife-torn country to maintain peace between the Christian south and the Muslim north and among various tribes. However, as the desert claims 350,000 ha (3,500 km², 877,000 acres) of rangeland and cropland each year, people are forced southward into already densely populated areas. The same population pressures, land degradation, and hunger that ignited social tensions in Rwanda are building in Nigeria" (Brown, 2003a).

Affecting each of the 10 northern states, desertification has emerged as Nigeria's leading environmental problem. "Since its population is expected to increase from 121 million today to 258 million in 2050. With a population in 2050 approaching that in the United States today, squeezed into a country only slightly larger than Texas, the handwriting on the wall is clear" (Brown, 2003a). In 2004, over much of northern Nigeria, friction between Muslim Fulani herders and Christian farmers was/is a major issue (see Chapter 6, Section 6.1.4.7, Impacts on pastoralism and range ecology from increases of human and livestock populations in the 20th century). As a result of "localized" conflict in Nigeria, at least 10,000 people lost their lives between 1999 and 2003 and an estimated 800,000 were internally displaced in ongoing localized violence and short-lived but vicious

communal fighting (Commission for Africa, 2005). It is likely these conflicts over scarce resources will only worsen as populations increase.

5.11.3 Land and Civil War, the Ivory Coast

See Section 5.7.4.4, Land reform and civil war in the Ivory Coast.

5.11.4 Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics

“The conflict began as an ecological crisis, arising at least in part from climate change. Two decades ago, rain in southern Sudan began to fail...average precipitation declined by 40% since the early 1980s...coincided with a rise in temperatures of the Indian Ocean, disrupting seasonal monsoons...It is no accident that the violence in Darfur erupted during the drought. Until then, Arab nomadic herders had lived amicably with settled farmers...But once the rains stopped, farmers fenced their land for fear it would be ruined by the passing herds. For the first time in memory, there was no longer enough food and water for all. Fighting broke out...Any peace in Darfur must be built on solutions that go to the root causes of the conflict...involves sustained economic development...such as genetically modified grains...irrigation and water storage techniques...new roads and communications infrastructure...health, education, sanitation...violence in Somalia grows from a similarly volatile mix of food and water insecurity. So do the troubles in Ivory Coast and Burkina Faso” Ban Ki Moon (2007), secretary general of the United Nations.

The crisis in Darfur is not new, maybe already 20 years old, the only difference being that CNN and BBC are broadcasting for the world to see, while 38,000/month die in the eastern DRC (Schlein, 2006) and the world seems oblivious since this receives little publicity on international television networks. Also with increasing populations the crisis is worsening. Rosenblum and

Williamson (1987) discuss famine in Darfur back in the 1980s and the logistics of getting 360,000 tons of sorghum to the starving people in this Western province.

The Darfur region in the north-western corner of Sudan, covers approximately 500,000 km², amounting to 20% of Sudan's territory. Darfur could be divided into six ecological zones as follows (Abdul-Jalil, 2005 *In: ACTS*, 2005):

1. The **desert zone** in the north covers 28% of Darfur and consists mainly of sandy stretches and dunes, little and very low precipitation (0-100mm), nomadic pastoralists raising cattle and sheep spending part of the year in this region.
2. The **semi-desert zone** lies south of the desert with sandy stretches covered by low grass and bushes of small trees, averaging 100-225 mm of rain/year, the main activities being livestock and some cultivation of millet in good years along *wadis* (water courses). In some places wells are dug and irrigated horticulture is practiced.
3. The **Jebel Marra Plateau** in centre of Darfur reaching 3,048 m (10,000 feet) above sea level is the major watershed of Darfur with good soil and stable rainfall of up to 1,000 mm/year, allows for intensive agricultural durra, millet, vegetables, citrus fruits (mainly oranges and grapefruits) and potatoes serving urban centers as far away as Khartoum.
4. The **Central Goz** extending east of Jebel Marra into the region of Kordofan consists of sandy plains (steppes) covered with bushes and short grass, 225-400 mm/year, suitable for sheep raising, marginal for millet cultivation, and since the 1970s for commercial oil seed cultivation (peanuts, sesame and water melon) as cash crops.
5. The **Alluvial Plains West Of Jebel Marra** with fertile clay soil, rainfall of 400-600 mm/year with large tree lined wadis originating from Jebel Marra (Baare, Azoom, Kaja, and Aribu) pass through different parts of

this zone that permits perennial horticulture in addition to rainfed cultivation, as well as serving camel nomads from the north during the dry season

6. The **Southern Plains** consist of stretches of sand intermingling with clay soil, otherwise termed “Baggara repeating pattern” by ecologists, with rainfall 600-750 mm/year, soils suitable for large-scale agricultural activities, but a lack of roads and other infrastructural inputs allows for only limited mechanized commercial agriculture. Expansion of oil seeds cultivation for the last two decades, and its “Baggara Belt” in recognition of its rich savannah pastures preferred by Arab cattle nomads roaming central Sudan.

Arab and African communities in Darfur have for decades intermittently clashed over land and scarce resources. As across the Sahel, the root of much of the conflict is competition over fertile land and water (DeCapua, 2004a; Human Rights Watch, 2004; ICG, 2004b), especially during the dry season of November to April, exacerbated by desertification in northern Sudan and the drought that has affected Darfur on and off since the 1970s. Nomadic groups of all origins from the northern semi-desert belt have been pushed southward in search of grazing lands and water. The regular presence of nomads and their herds in Darfur's agriculturally rich central belt has caused friction with farmers. Ecological decline and a lack of development in the entire region have combined to impoverish Darfur people of all ethnic backgrounds (Human Rights Watch, 2004; ICG, 2004b).

There are at minimum 36 main tribes, but some sources cite as many as 90 by including subdivisions or clans. This mix is composed of two major blocks, nomadic Arab camel herders and non-Arab (blacks believed to have originated

from Chad), the latter known locally as *Zurga*, or “blacks” (Human Rights Watch, 2004; ICG, 2004b).

“Centuries of coexistence and intermarriage have reduced distinctions to the cultural identification or non-identification with the Arab world as members of both groups are dark-skinned. Except for the Zaghawa, who specialize in herding camels, the indigenous black African groups depend on subsistence farming and animal husbandry, while groups of Arab extraction live on camel herding in northern Darfur and cattle herding in southern Darfur” (ICG, 2004b).

All groups are Muslim. One observes distinctions more along divisions of clan, labor and cultural identify rather than pure racial or religious lines compared to the problems between Khartoum and southern Sudan (see Chapter 13, Section 13.10.1.6, Oil-scorched earth Sudan). Thus, the “word ‘Arab’ represents a cultural rather than a racial identity” meaning Arabic-speaking people, who have mixed with the indigenous non-Arab Sudanese and who physically bear more similarities with Africans than with the people of the Arabian Peninsula (Abdul-Jalil, 2005 *In: ACTS*, 2005).

The indigenous Darfurian tribes consist mainly of settled farmers and small-scale traditional cultivators, of whom the Fur is the largest tribe and founder of the Fur Sultanate, the traditional rulers of the region. Other non-Arab tribes include Zaghawa nomads, Tunjur, Meidob, Masalit, Berti, Tama, Mararit, Mima, Daju, and Birgid and Fallata (cattle herders). Arab tribes include the Rezeigat, Habbaniya, Bani-Halba, Taisha, Maaliya, Salamaat plus some smaller groups, all cattle nomads living in southern Darfur. In northern Darfur live the Bani Husain cattle nomads plus Zaiyadiya and northern Rezeigat (a collective name for Mahameed, Mahriya, Eraigat, Etaifat, and Awlad-Rashid) who are camel nomads. Other than the development of the rich central region, Darfur suffers from being an undeveloped region in an undeveloped country. The main contribution of

Darfur to the national economy is its livestock sector, accounting for 30% of the national livestock trade and 25% of the national livestock population. This sector is dominated by an elite merchant class, mainly from central riverian areas (commonly known as *Jellaba*), middlemen for the internal market and the international livestock trade that from 1978-1984 accounted for 20% of Sudan's GDP (Abdul-Jalil, 2005 *In: ACTS*, 2005).

Historically, the indigenous groups and earlier settled Arab migrants each had their own *dar* (tribal homeland or traditional management area) (ICG, 2004b; Abdul-Jalil, 2005 *In: ACTS*, 2005). Tribal homelands were named after the tribe (e.g., *Dar Zaghawa* or land of the Zaghawa people and *Dar Rezeigat* or land of the Rezeigat people) (Abdul-Jalil, 2005 *In: ACTS*, 2005). The major tribes voluntarily agreed to settlement of other groups and accorded them a recognized administrative status (ICG, 2004b; Abdul-Jalil, 2005 *In: ACTS*, 2005).

Until the outbreak of the current inter-ethnic civil war, many nomads kept animals for their sedentary friends, while farmers would reciprocate through gifts and giving access to the remains of agricultural produce for fodder during the dry season. While cattle-herding Arab groups occupying most of southern Darfur estate (Rezeigat, Habbania, Taisha, Beni Halba) traditionally had their own *dars*, the Arab camel nomads of northern Darfur did/do not have *dars* of their own. Communal land can be further subdivided (Abdul-Jalil, 2005 *In: ACTS*, 2005):

- “At the communal scale, each tribe has a given land as a *dar*.
- Within the tribal *dar*, there is the clan ownership with a known boundary
- At the village level, there is the village land where each villager practices his private ownership respected by all.
- Unclaimed land, used as rangeland or allotted to “strangers” (migrants) by the village head’.

Disputes between nomads and farmers were resolved through negotiation between traditional leaders on both sides, compensation for lost crops, and agreements on the timing and routes for the annual migration (Human Rights Watch, 2004).

The full scale civil war dating back to 1985 at the height of the drought,

“the nomadic ‘scramble’ from the impoverished *Dars* into the rich agricultural central heartland is the cause of the continuing conflict; it is the contest of the drought-stricken for the green oasis. The conflict is being fought primarily over the control of a thriving resource base in the middle of a zone of scarcity. It is a classical ecological conflict” (Abdul-Jalil, 2005 *In: ACTS*, 2005).

In addition, Darfur’s population has multiplied nearly 5 times since 1973 from 1,350,000 to 6,480,000. This has resulted in decreased fallow and decreased productivity, loss of dry season migratory routes (*marahil*) for nomadic pastoralists, increased livestock populations linked to entering a market economy, which along with increasing commercial agriculture all contributed to land degradation and desertification (e.g., from tree-felling, excessive cultivation and over-grazing). Over-grazing in the semi-desert and *goz* zones resulted in carrying capacity going from 40-50 animal units/km² in the 1970s to 9 animal units/km² in 2002 (Abdul-Jalil, 2005 *In: ACTS*, 2005).

However, “the fact that the central government is heavily involved as a stakeholder in the war makes it difficult to conclude that the current civil war in Darfur is only driven by competition over resources” (Abdul-Jalil, 2005 *In: ACTS*, 2005).

The Khartoum government tampering with these traditional systems has had the cumulative effect of seriously disrupting co-existence, especially by promoting ethnicity and political divisions (ICG, 2004b). In 1986, a number of Arab tribes formed what became known as the “Arab alliance” (*Tujammo al Arabi*) aimed at establishing their political dominance and control of the region (Human Rights

Watch, 2004). Government intervention involved “redrawing traditional political boundaries” and handing these politicized as opposed to management units over to “Arab” dominated groups to administer. For instance, the traditional homeland of the Massaleit (Masaalit) ethnic group was divided into 13 Amarat (principalities), of which five were allocated to Arab groups. This is believed to have been part of a broader scheme that resulted in redrawing the nine states into 26 and 18 provinces into 72, centralizing bureaucratic control by Khartoum as opposed to decentralizing and empowering the grass roots as had been promised. Some argue that this was undertaken to tighten the nationwide grip of the National Islamic Front (NIF) by placing its members and co-opted clients in position of influence (ICG, 2004b). This might be considered a form of gerrymandering. This is further complicated by a split in the Islamic movement that had taken over Sudan in 1989.

“Following a disagreement with Hassan el-Turabi, the architect and spiritual guide of the Islamist movement, the top NIF cadre in Darfur, Yahiya Ibrahim Bolad, defected to the SPLA and led its 1991-1992 offensive into the region. In response the government armed and mobilized Arab tribal warriors and portrayed the insurgency as an uprising by the Fur people. The success of the strategy cemented Khartoum's alliance with Darfur Arab fighters....Turabi, then speaker of parliament, formed the Popular National Congress (later renamed the Popular Congress, PC) following a fierce power struggle with the ruling National Congress Party. To broaden its base, PC activists reached out to Sudan's majority but marginalized African (black) population. The PC even signed an agreement with the Sudan People's Liberation Army (SPLA) in February 2001 in which the two parties undertook to pursue the ouster of the (Omar) al-Bashir government by peaceful means. The government reacted by banning PC activities and detaining many of its leaders, including the elderly Turabi, until late 2003” (ICG, 2004b).

el-Turabi was/is an ally of Osama bin Laden, having given him and his family refuge from Saudi Arabia after the 1991 Gulf War, when Saudi Arabia decided to

allow American and European soldiers to be permanently based on Saudi soils and the House of Sa'ud in essence forced bin Laden into exile (Bodansky, 2001). Government intervention, from disregard for traditional management systems and politicization of ethnic divisions, resulted in fighting for the first time from 1987-1989 between “27 allied nomadic Arabs tribes” and the sedentary Fur ethnic group over-grazing and water rights. The Fur are said to have lost 2,500 people and 40,000 cattle and had 400 villages burned, causing tens of thousands to go to Internally Displaced Persons (IDPs) camps. A thriving fruit and vegetable farming sector was crippled as nomadic raiders destroyed fruit trees and burned irrigation pumps and tractors. The Arab groups lost 500 people and had hundreds of camps burned (ICG, 2004b).

Fourteen months ago two new rebel groups emerged, the Sudan Liberation Movement/Army (SLM/A) and the Justice and Equality Movement (JEM) that demanded the Sudanese government stop arming the Arab “Janjaweed” militias in Darfur and address under-development in the region (Human Rights Watch, 2004). In early 2003, these rebel groups attacked a military installation (ICG, 2004b). Human Rights Watch (2004) estimates this militia to be at 20,000.

The Janjaweed is built on a tradition of the *Hambati* or “social bandits”, or robbers rejected by their communities for flouting established traditions but envied for their exploits. Other elements are thought to be professional criminals, some allegedly released by government to join or lead the militia.

“Building on existing ethnic tensions and a raider culture, the government armed the Janjaweed to supplement the army and gave carte blanche for looting and rape” (ICG, 2004b).

The most frequently mentioned groups of Janjaweed are the Irayqat and Ouled Zed subclans of the camel herding northern Rizeigat, the Mahariya, and the Beni

Hussein. New recruits to the Janjaweed militia received an initial fee that could range from US\$ 100 to US\$ 400 with relatives guaranteed support should a militia member be killed in battle. Many Janjaweed receive monthly stipends exceeding the salary of army soldiers (about 100,000 Sudanese pounds or \$100) as well as regular supplies of sugar and oil. They also receive arms, uniforms, communications equipment and identity cards from the Sudanese government (Human Rights Watch, 2004).

All of this was compounded by leaders of the various factions seeing this as a chance to advance themselves politically, socially and economically. They used as models, former Chadian President Hissène Habré and the man who replaced him, President Idriss Déby, a Zaghawa who trained ethnic militias in the Darfur area, launching campaigns to seize power in 1982 and 1990 respectively (Human Rights Watch, 2004; ICG, 2004b).

“Déby came to power in 1990 through a support from Zaghawa Khartoum-based insurgency that supported him in the overthrow of ex-President Hissène Habré...The Sudan Liberation Movement/Army (SLM/A) and Justice and Equality Movement (JEM) rebel groups were initially dominated by Zaghawa, and the support of the Chadian Zaghawa community and, unofficially, many Zaghawa whom Déby brought into the Chadian military, has been important for both groups. The SPLA is also alleged to have played a role in supporting the SLA in its initial stages, although its support is believed to have been minimal since the peace talks began” (Human Rights Watch, 2004).

However, in April 2004, Sudan People’s Liberation Army (SPLA)’s John Garang, left the peace talks for a few days to meet in Eritrea with SLM leader Abdulwahid Mohammed Ahmed and was accused by the Sudanese government of supporting the rebels in Darfur (Ryu, 2004). Garang died in a helicopter crash in 2005 (see Chapter 13, Section 13.10.1.6, Oil-scorched earth Sudan).

Like much of Africa and the cause of many of Africa's problems in the 20th and 21st centuries. These countries were divided along colonial lines with ethnic groups naturally traversing both borders. This offers refuge from one country to the next for dissidents who can hide among their ethnic group.

One of the major differences between the north/south fighting with the SPLA as opposed to Darfur in the west is that against the SPLA

"the Sudanese government recruited volunteers to fight in the south on the basis of '*jihad*,' or a religiously-sanctioned war against the largely non-Muslim southerners. In Darfur, in contrast, the communities under assault are Muslim, but that has not proved to protect them from the same abusive tactics...The rebels and their communities believe that the real motivation for this conflict is the 'Arabizing' (rather than Islamic or Muslim) thrust of this and previous Sudanese governments" (Human Rights Watch, 2004).

Taking advantage of the internationally regulated cease-fire in the south, the Sudanese government's response was to shift its Antov's and Mig aircraft as well as attack helicopters and other heavy weapons, purchased with oil revenue from the south, to the western region of Darfur. A massive bombing campaign in 2003 combined with the raids of the marauding militias, have forced more than 800,000 people from their homes and sent an additional 110,000 people into neighboring Chad (Human Rights Watch, 2004; ICG, 2004b; Sheridan, 2004). By July 2004, an estimated 30,000 people had been killed and 1 million had been displaced (DeCapua, 2004b; VOA, 2004a). By October 2004 these figures were raised to 70,000 killed and 1.5 million displaced (Gollust, 2004). Other estimates are of 10,000 people dieing/month (Heinlein, 2005a). By May 2005, an estimated 180,000 people had died since the outbreak of the war two years ago (Heinlein, 2005b).

In a scorched-earth campaign, government forces and Arab “Janjaweed” militias have killed several thousand civilians from the Fur, Zaghawa and Masaalit ethnic groups, routinely raped women and girls, abducted children, and looted tens of thousands of cattle and other property. In many areas of Darfur, they have deliberately burned hundreds of villages and destroyed water sources and other infrastructure, making it much harder for the former residents to return (Human Rights Watch, 2004; ICG, 2004b). Over the past months however, members of some smaller tribes such as the Jebel and Dorok peoples have also joined the rebellion following “Janjaweed” militia attacks on their communities (Human Rights Watch, 2004). ICG (2004b) believes that this is an indiscriminant attack on civilians and the widespread destruction of schools, clinics, wells and irrigation pumps is an effort to permanently displace these ethnic groups; a form of ethnic cleansing of the area. Human Rights Watch (2004) accuses the local rebel groups of similar atrocities against civilian groups.

ICG (2004b) accuses the Khartoum government of deliberately slowing down the Naivasha peace negotiations, knowing it would not be condemned by the international community, to give it time for the offensive in Darfur. In fact, in April 2004 George W. Bush recommended to Congress not to impose sanctions on either the Sudan government or the SPLA mandated by the U.S. Sudan Peace Act, accepting that although the peace process in Naivasha was moving slowly, it was moving. “The Bush administration has aggressively pursued a government-SPLA peace agreement, while its approach to the Darfur conflict has generally lacked the same urgency” (ICG, 2004b). There was also concern that by mixing the Darfur issue with the SPLA/Khartoum peace agreement process, that this process could be derailed. However, the 1997 U.S. economic embargo against Sudan was continued because its actions and policies were considered a threat to U.S. national security and foreign policy (ICG, 2004b). The priority of the

SPLA/Khartoum peace talks over Darfur, likely has much to do with access by Western interests to oil that occurs in the south.

The implications of this conflict go far beyond Darfur's borders, indirectly threatening the regimes in both Sudan and Chad with the potential to inspire insurgencies in other parts of the country. The Beja Congress, an ethnically based armed group from eastern Sudan, has already allied itself with the SLA, other groups could emerge -- east and west -- in an anti-government coalition. Even SPLA elements from the Kordofan region of the Nuba Mountains demanding a fair share in the oil wealth and Southern Blue Nile might be attracted back to the battlefield should they become dissatisfied with the Inter-Governmental Authority on Development (IGAD) talks (ICG, 2004b) in Naivasha, Kenya. Human Rights Watch (2004) reports of regular attacks of villages by Janjaweed across the border in Chad, risking to destabilize this area. This has also ignited tensions among Chadian ethnic groups that share blood ties with Darfurians, and as in Sudan, previously coexisted in Chad. Interestingly enough, Chadian military forces have conducted cross-border hot pursuit of the "Janjaweed" into Sudan with the Sudanese government's permission. "Darfur is a stark reminder that Sudan's crisis has more to do with the structural imbalances of governance and economic development that characterize the relations of the center with peripheral regions than with the north/south divide" (ICG, 2004b).

Further complicating the picture, fighting between the government and the SPLA resumed in several areas since the end of January 2004 despite the cessation of hostilities agreement. In the western Upper Nile oilfields, the trigger was defection to the SPLA of two commanders of the pro-government South Sudan Defense Forces (SSDF), Tito Biel and James Lieh Diu. Combat likewise flared up between government-aligned militias and the SPLA in the Shilluk Kingdom in the southeast where Dr Lam Akol's former government-aligned SPLM/United merged

with the SPLA in November, 2003 (ICG, 2004b). In April, a tentative peace accord was signed between the SPLA and Khartoum, (see Chapter 13, Section 13.10.1.6, Oil-scorched earth Sudan). Time will tell if this accord is lasting and if it will positively impact what is happening in troubled Darfur.

“Washington issued on 2 March 2004 its strongest public statement to date, expressing grave concern about the deepening crisis and condemning the Janjaweed and other government-supported militia, who ‘continue to attack and burn undefended villages, murdering and raping the inhabitants...’” (ICG, 2004b). By July 2004, the African Union agreed to send 300 peace keepers to the area (VOA, 2004b), while Sudan agreed under pressure from the United States and United Nation to lift restrictions on the movement of food aid and relief workers into Darfur (Nunan, 2004). While global bureaucrats argue over the nuances of whether what is happening is “genocide”, “ethnic cleansing”, or some other term, nothing is being done to stop the slaughter. By September 2004, the United States declared the Darfur crisis as genocide (VOA, 2004c) and the United Nations threatened sanctions against Sudan if the killing was not stopped. By October 2004, the U.S. provided US\$ 40 million in ground facilities and other services to African Union (AU) troops, including airlifting these troops, expected to grow from 300 to 3,000, into the area (Gollust, 2004; Heinlein, 2005b). A January 1, 2005 report by the UN International Commission of Inquiry on Darfur has refused to label what is happening as a genocide but states that this is “widespread and systematic” abuse that may constitute crimes against humanity (Lynch, 2005), following the same pattern that led to a million people being killed in Rwanda and Burundi in 1994 (see Chapter 13, Section 13.8.6, Former Cold War Allies Vying for Power in the Great Lakes Region). There is some talk of war tribunals.

By early August 2007, an estimated 200,000 Darfurians are dead and 2.5 million have fled there home. The UN Security Council has just approved a 26,000-

strong hybrid UN/African Union peacekeeping force for Darfur. With support from the African Union and the United Nations, eight rebel groups meeting in Arusha, Tanzania have agreed upon a common negotiating position for proposed peace talks with the Sudanese government. Some rebel groups have refused to participate. Of concern is the absence of Abdel Wahid Mohammed al-Nur, leader of the Sudan Liberation Movement/Army (SLM/A) and one of the founders of the Darfur uprising. He refuses to participate until UN troops are in place and there is a no-fly zone (Wadham, 2007a).

Meanwhile, at almost the same time a mega-underground aquifer has been found in Northern Darfur (Polgreen, 2007). Although not an issue at the moment in Darfur, concern exists that this may spur a form of government backed commercial agriculture (Polgreen, 2007) that elsewhere in Sudan has displaced traditional farmers and tenure systems in legalized land grabs, resulted in forced labor, and empowered external investors looking for a quick profit often resulting in abusive environmental and labor practices. Grants and interest free loans have been provided by the International Development Association (IDA), part of the World Bank (CIJ, 2006; Polgreen, 2007). This has resulted in massive deforestation as tree cover is cleared in the first year of mechanization and sold as charcoal. Conflicts with nomadic pastoralists are common as their traditional grazing areas go under the plow and are no longer available. In many instances this has resulted in soil mining and ultimately what some call “mechanized desertification”. Often local communities are left impoverished, never to recover psychologically or environmentally from exhausted land that will no longer produce agriculturally or provide vital resources (e.g., honey, wild fruits, game) once found in surrounding natural systems vital as nutritional supplements to itinerant agriculture. It is argued that over the last 15 years commercial farming has been a key military strategy to break communities considered hostile to the Sudanese government and to further the Islamization of the society (CIJ, 2006).

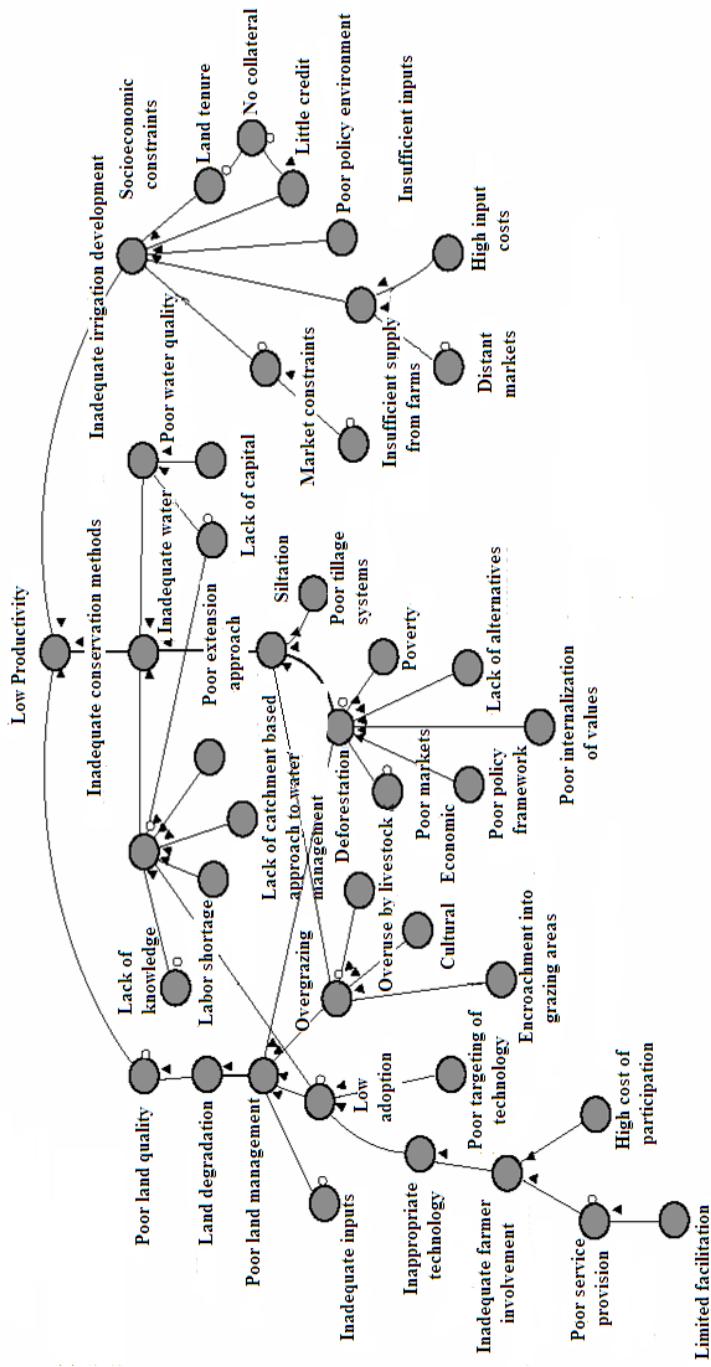

Will this underground lake be a source of continued conflict, or help solve this bloodshed? The Darfur conflict is a

“battle for control of resources and riches, but not between farmers and herders, northerners and southerners, Christians and Muslims, or Arabs and non-Arabs. It is a conflict between those at the center of the country, the elites who have controlled Sudan and its wealth for the past century and a half, and the desperately poor people who beg for scraps from the periphery” (Polgreen, 2007).

5.12 THE WAY FORWARD

Murwira (2004 *In:* Bationo, 2004) identifies key constraints to agriculture and rural development in Sub-Saharan Africa, which must be overcome (Figure 5.12). Eicher (1990 *In:* Eicher & Staatz, 1990) has identified four major classes of farmers in today’s Africa:

1. Resource poor farmers who are net buyers of food, who rent their family as laborers on other farms and who engage in rural non-farm activities as a means of generating income to purchase food;
2. Smallholders and herders relying mainly on family labor to produce food, livestock and export crops for domestic and international markets;
3. Middle “*progressive farmers*” who own and operate farms using oxen and hired labor and who are able to serve as innovator farmers to test and demonstrate new methods to poorer farmers; and
4. Large-scale farmers, a new emerging class coming out of the elite (soldiers, merchants, civil servants, and the new professional class) – often absentee farmers.

Source: Murwira (2004 *In: Bationo, 2004*) with permission, *Centro International de Agricultura Tropical* (CIAT).

Figure 5.12: Constraints to rural development and sustainable agriculture that must be overcome in Sub-Saharan Africa

He argues that different technological packages/arrangements will be needed depending on the type of farmer. Linked to these farmers are the “prime movers” necessary for African agricultural development (Eicher, 1990 *In:* Eicher & Staatz, 1990):

1. Favorable economic environment from an enabling political system – good governance, rule of law, etc.
2. Human capability and managerial skills – education;
3. New technologies and borrowing already existing technologies to improve production;
4. Rural capital formation, both physical (e.g., roads, grain storage facilities, dams, irrigation) and biological (e.g., improved livestock, and seed); and
5. Rural institutions such as those that provide credit, seed and marketing to/for the farmer.

“Food security is becoming or is already of paramount concern in many of the African nations. Traditional agriculture systems and declining 'aid' imports may not supply the needs of a region, which has some of the highest birth rates. A declining resource base will eventually contribute to civil unrest due to uncertain food supplies” (Eswaran, *et al.*, 1996) unless major steps are taken.

Africa will be faced with three major food strategies (Maxwell, 2001 *In:* Devereux & Maxwell, 2001a) (Table 5.26):

- **Growth First Strategy** – growing food on high potential lands, which may or may not be food crops.
- **Food First Strategy** – maximizing food output in high potential lands in favor of commercial crops such as coffee, tea, peanuts, wildlife and other cash crops.
- **Food Security First Strategy** helping the poor to acquire food by production, purchase or gift.

Table 5.26: Agricultural development/food strategies

Agricultural Development Strategy	Growth	Impact on Poverty Reduction	Food Import Reduction	Commercial Import Capacity	Reduction In Food Aid Need
Growth First	High	Medium	Medium	High	Medium
Food First	Medium	low	High	Medium	Low
Food Security First	Low	Low	Low	Low	High

Source: Maxwell (2001 *In: Devereux & Maxwell, 2001a*) with permission, ITDG Publishing/University of Natal Press.

The authors advocates a middle of the road approach tending towards the “Growth First Strategy”, which has the greatest potential to develop more jobs from the added value of transformation, assuming it takes place in African agro-industries, while providing people with the buying power to purchase food in both times of plenty and scarcity. It then becomes irrelevant in a global economy if food is produced locally or imported, as long as access to the food is available through local buying power by:

- Identifying high-yield lands and assuring they produce food and or transformable commercial crops depending upon the comparative advantage of the area in soils and climate. This may require “Green Revolution Technologies”. The decision to grow food or exportable produce will depend upon factors such as global grain supplies and national versus international tariffs and subsidies. The important factor is that there needs to be the wherewithal for the farmer to switch crop production, depending on supply and demand, to assure national/regional food security if global shortfalls become chronic, as some predict from a combination of factors such as population growth, global warming or declining soil fertility resulting in declining yields;

- Using transformation (agricultural, mineral, timber, wildlife, etc.) and industrialization to draw people off the land, especially marginal lands, into urban centers where these industries and eventually information technologies will provide employees with the buying power to purchase their food; and
- Working with traditional farmers in marginal areas, where the majority of Africa's population lives, to combine traditional land management with low cost soil enhancing techniques (described below) while continuing to experiment in increasing yields through improved crop varieties, inputs (fertilizers and pesticides) where they can be shown to be both economically and environmentally sustainable and other soil enhancement measures.

The authors are somewhat pessimistic about significantly increasing production on marginal lands, especially in savanna and forest areas where after spending billions of dollars over the past 40 years, no Green Revolution has taken place, and if possible, would likely only take place through subsidizing the costs of production, with costs outweighing benefits. Often soil moisture, fertility, chemistry and structure, as well as rainfall and other climatic factors are major constraints to increased production over much of Sub-Saharan Africa. Eicher (1990 *In: Eicher & Staatz, 1990*) as well as René Dumont (1966) are also pessimistic about increasing the productivity of staple foods in dry areas where there is a paucity of irrigation and a lack of profitable technology for the staple foods of sorghum and millet, as well as a lack of technical research on fruits and vegetables.

Maxwell (2001 *In: Devereux & Maxwell, 2001a*) believes that with proper national policies, the private sector will take over and run the high potential lands, while the state should work with the poor in low potential areas. At this point in

Africa's history, the private sector implies white Africans and/or foreign companies. There is a crying need to see commercial technologies transferred to black Africans. This is discussed in some detail below.

According to Nana-Sinkam (1995), the main technical options open to African governments to increase food production are:

- Land and optimal irrigation development or water policy in general;
- Increasing land and labor productivity with available technology;
- Developing additional technology to overcome production constraints that currently have no technical solutions; and
- Institutional framework including land tenure policy.

These options must be put into their proper perspective since misleading claims have been made for them. In fact, there are four myths about how these options can solve Africa's agricultural crisis. They assume, which is not the case, that Africa has (Nana-Sinkam, 1995):

- Huge areas of surplus land available, which is not true;
- Plenty of agricultural labor available, when urban migration and increasingly HIV/AIDS are creating labor shortages;
- There is a vast potential for irrigation; and that
- These can be married with the use of agricultural technologies that have been successful in Asia.

The 27% of land suitable for rainfed agriculture in Sub-Saharan Africa amounts to about 600 million ha of land; 663 million ha for all of Africa (FAO, 2003b). Soils without or having moderate constraints in Sub-Saharan Africa include:

	<u>Hectares (x 1, 000)</u>	<u>Percentage (%)</u>
West Africa:	163,843	28
Central Africa	142,059	24
East Africa	234,763	39
Southern Africa	<u>55,826</u>	<u>9</u>
	596,491	100
<u>North Africa</u>	<u>65,955</u>	
TOTAL	662,446	

Source: FAO (2003b)

Nana-Sinkam (1995) estimates that 600 million ha for the entire continent are suitable for rainfed agriculture in Africa.

As previously discussed in this chapter, much of the really good land is already under production, in fallow that is rapidly disappearing or in other land uses (see Section 5.51, Land Use Potential for Rainfed Agriculture in Africa and Section 5.9.2, Over-Population of Prime Agricultural Land for Low Input Agriculture is also Commercially Viable Land). Some is only suitable for tree crops and most is already in use for forestry or grazing (Nana-Sinkam, 1995), while some areas are over-populated by subsistence farmers. In some areas (e.g., Maasailand in Tanzania & Kenya), there are major decisions which will have to be made; will the high altitude grasslands remain as rainy season dispersal areas for wildlife and livestock, or will they be converted to cereal producing areas? Nana-Sinkam (1995) estimates that about 75% of reserve land available for crop production is located in three sub-regions (Table 5.20): Central Africa, where development will be held back by low population densities, and limited road and rail access; and East and Southern Africa, where 67% of the reserve lands have marginal soils and/or unreliable rainfall and are located mainly in four countries - Angola, Mozambique, Tanzania and Zambia. South Africa and Zimbabwe should be added to this list, though the current land reform policies have destroyed any hope in the near future of Zimbabwe serving as a breadbasket for Southern Africa. Ultimately, there is a need to identify prime agricultural land already in

production and assure that it remains so, while identifying prime land not in production and making plans to put it into production to feed the continent, unless it can be shown that other land uses (e.g., wildlife dispersal areas in East Africa) are economically and/or ecologically advantageous.

“Land frontiers are closing rapidly in the coastal zone of West Africa and in the densely populated moist and dry savannas, and to a lesser extent in Central Africa, agricultural intensification becomes a necessity in terms of higher yields per hectare, and land-use intensification in terms of shortening fallows” (IFAD 2001).

The Commission for Africa (2005) suggests that

“at present agriculture has just two focuses: growing crops for subsistence and for export to the industrialized world. If a third is added – to grow staple foodstuffs for those parts of Africa which have regular food shortages – then agriculture could bring growth to areas which could be breadbaskets. That would simultaneously redress the situation where at least 25% of the population is undernourished and close to half of African countries experience routine food crises. It would also reduce the need for food imports on the present scale – US\$ 22 billion worth of food with a food aid complement worth US\$ 1.7 billion in 2002. With an increasing population, markets in staple foods will be the fastest growing of all agricultural markets in Africa over the next 20 years”.

5.12.1 Technological Solutions to Africa Food Crisis and Land Degradation

“FAO estimates show that between 1995/7 and 2030 about 75% of the projected growth in crop production in Sub-Saharan Africa will (have to) come from intensification in the form of yield increases (62%) and higher cropping intensities (13%), with the remaining 25% coming from arable land expansion...If most of the nearly 70 million smallholder families in Sub-Saharan Africa (Sub-Saharan Africa) fail within the next decade to adopt sustainable integrated soil fertility and land and water management practices on their farms, they will seriously jeopardize their long-term food security,

productivity and incomes while environmental degradation will accelerate. Africa needs to address low farm productivity through integrated approaches combining increased use of organic matter, mineral fertilizers, hybrid seeds, irrigation or mechanization (including reduced tillage systems) rather than each in isolation” (NEPAD, 2002).

Land intensification requires more inputs/ha, particularly labor inputs. Agricultural and land-use intensification help to preserve the environment, including nature reserves, wetlands, fragile areas, game reserves and mangroves. Without intensification, such areas will be brought under extensive cultivation (IFAD, 2001). Application of the ‘*Green Revolution*’ strategy in Sub-Saharan Africa resulted only in minor achievements because of a variety of reasons. At the same time environmental degradation, resulting from massive applications of fertilizers and pesticides in Asia and Latin-America between the mid-1980s and early-1990s using Green Revolution technologies and the abolition of the fertilizer subsidies in Sub-Saharan Africa from structural adjustment policies (SAPs) led to a renewed interest in organic resources in the early 1980s. Management of soil productivity in Sub-Saharan Africa shifted from mineral inputs only to Low Mineral Input Sustainable Agriculture (LISA) where organic resources were believed to enable sustainable agricultural production. From the mid-1980s to the mid-1990s, there has been a paradigm shift towards the combined use of organic and mineral inputs (Vanlauwe, 2004 *In:* Bationo, 2004). Intensification will require improved production through adoption of Integrated Soil Fertility Management Technologies (ISFM) (CIAT, 2002):

- Integrated nutrient management (INM);
- Micro-dose use of fertilizers;
- Improved manure management;
- Inter-cropping systems;
- Integration of multi-purpose legumes;

- Improved fallow (e.g., shortened fallow with the addition of fertilizer – Dumont, 1966); and
- Biomass transfer of high quality organic inputs

Improved seed varieties will also be required. In many instances this implies integrating traditional technologies and knowledge (e.g., use of manure and traditional nitrogen fixing legumes, use of colonizing vegetation to know when fallow lands are recovered, etc.) with modern technologies.

However, for most African farmers, globalization of agricultural markets will make no significant difference to their livelihood opportunities until considerable improvements are made in infrastructure and marketing institutions. Modern, input-intensive farming is unlikely to be economically viable in much of rainfed Africa for at least another two to three decades, until rural infrastructure, markets, and agricultural input supply systems have caught up (Hazell, 2001) (see Section 5.12.1.8, Infrastructure technology as an incentive to increased agricultural production). The cost of getting nitrogen fertilizer to the farm gate in Africa is from 3-5 times higher than in North America and Europe (Hazell, 2001; Sanchez & Jama, 2002 *In: Vanlauwe, et al., 2002*) and the farmer receives only 30-60% of the market value for his/her products (Hazell, 2001). The principal author recalls being in an isolated village in the Fouta Djallon of Guinea-Conakry awash with mangoes but no way to get them to major market centers.

Agricultural intensification does not necessarily mean more external inputs, which may be damaging to the environment (IFAD, 2001). In the meantime, most of rural Africa, particularly small-scale farmers in rainfed areas, will need to look to lower cost alternatives to intensification such as Low External Input (LEI) farming technologies (Hazell, 2001; Madeley, 2002).

5.12.1.1 Integrated nutrient management (INM)

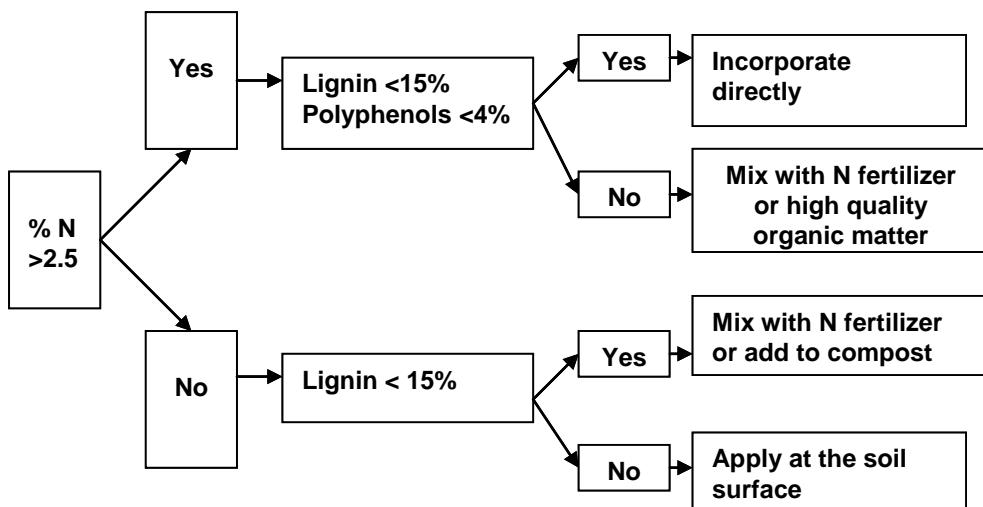

Gruhn *et al.* (2000) believe that fertilizer use in Sub-Saharan Africa is too low due to highly insecure supplies, and a high aversion to the risks by farmers with food production in marginal agro-climatic and socioeconomic conditions. As long as agriculture remains a soil-based industry, increased crop yields will require an adequate and balanced supply of nutrients. Integrated Nutrient Management (INM), a form of Low External Input (LEI) farming, maintains soils as storehouses of plant nutrients that are essential for vegetative growth. INM's goal is to integrate the use of all natural and man-made sources of plant nutrients, so that crop productivity increases without sacrificing soil productivity of future generations.

While plants have no preference of mineral versus organic fertilizers, the microorganisms needed to maintain healthy soil conditions prefer organic fertilizers (Sanchez & Jama, 2002 *In:* Vanlauwe, *et al.*, 2002). Sanchez and Jama (2002 *In:* Vanlauwe, *et al.*, 2002) argue that a combination of mineral and organic fertilizers could help to significantly improve soil fertility in certain areas of East and Southern Africa. Soil conservation technologies prevent the physical loss of soil and nutrients through leaching and erosion and fall into three general categories (Kumwenda, Waddington, Snapp, Jones & Blackie, 1996 *In:* Gruhn, *et al.*, 2000; Hazell, 2001):

- Terracing, alley cropping, and low-till farming alter the local physical environment of the field and thereby prevent soil and nutrients from being carried away;
- Mulch application, cover crops, inter-cropping, crop rotations, and biological nitrogen fixation act as physical barriers to wind and water erosion and help to improve soil characteristics and structure;

- Organic manures such as animal and green manures also aid soil conservation by improving soil structure and replenishing secondary nutrients and micronutrients; and
- Lower cost locally produced phosphate fertilizers.

Vanlauwe (2004 *In:* Bationo, 2004) provides a Decision Support System (DSS) for organic matter based upon resource quality parameters including macronutrient, lignin and polyphenol contents of fresh leaves, litter, stems and/or roots from almost 300 species found in tropical agro-ecosystems (Figure 5.13). DSS makes practical recommendations for the appropriate use of organic materials, based on their nitrogen (N), polyphenol,⁹² and lignin⁹³ contents, resulting in four categories of materials. DSS recognizes the need for certain organic resource to be applied together with mineral inputs.

Source: Palm, Gachengo, Delve, Cadisch and Giller (2001 *In:* Vanlauwe, 2004 *In:* Bationo, 2004) with permission, CIAT.

Figure 5.13: Decision support system (DSS) for organic matter management in soils

⁹² Vegetable substances with one or more phenolic group, giving plants colors, reacting to produce gelatins, alkaloids and other proteins, having anti-oxidant activity.

⁹³ Phenolic compound impregnating and strengthening cell walls in plants giving wood its stiffness

This will result in optimum management of soil resources including, organic and mineral inputs, as well as Soil Organic Matter (SOM) (Vanlauwe, 2004 *In: Bationo, 2004*).

The pros and cons of different techniques used in organic matter management, which also can enhance nutrient inputs are contained in Table 5.27 (Vanlauwe, 2004 *In: Bationo, 2004*).

Cereals grown in rotation with leguminous plants can absorb the nitrates released from the decaying roots and nodules of the leguminous plants. Experiments have shown that rice-legume rotations can result in a 30% reduction in chemical fertilizer use (Pingali & Rosegrant, 1994 *In: Gruhn, et al., 2000*). Madeley (2002) considers most of these technologies as “traditional” which can be lost within one generation of being pushed into using “modern agricultural” but not necessary cost-effective technologies for the scale of farming and physical/chemical conditions. Thus, these “traditional farming technologies” may have to be relearned. Examples of these traditional systems are briefly highlighted in Chapter 2.

Table 5.27: Pros and cons of different techniques used in organic matter management

Place and time of organic matter production – example of farming system	Advantages	Disadvantages
Same place same time -Alley cropping	-Safety net hypothesis (complimentary rooting systems) -Possible direct transfer from N ₂ fixed by legume species	-Potential competition between crop and fallow species -Reduction of available crop land
Same place different time -Crop residues -Legume-cereal rotation -Improved tree fallows -Manure, derived from livestock fed from residues collected from field	-Rotation effects (N transfer, improvement of soil P status) -Potential inclusion of dual purpose legumes -In-Situ recycling of less mobile nutrients -No competition between fallow species & crops	-Land out of crop production for a certain period -Decomposition of organic matter may start before crop growth (potential losses of mobile nutrients, e.g., N, K...) -Extra labor needed to move organic matter (manure)
Different place -Cut & carry systems -Household waste -Animal manure, not originating from same field	Utilization of land/nutrients otherwise not used -No competition between fallow	-Extra labor needed to move organic matter -No recycling of nutrients on crop land -Need for access to extra land -Manure & household waste often low quality

Alley cropping is an Agroforestry practice in which a row of crops are grown between rows of leguminous shrubs/trees in whose roots bacteria fix atmospheric nitrogen making it available to other plants as fertilizer.

Low-Input Agriculture in Ethiopia

Ethiopia with 700,000 small scale farmers growing coffee is Africa's third largest exporter of this commodity behind the Ivory Coast and Uganda. Ethiopia exported about 2 million 60 kg bags in 2000, accounting for 65% of its Foreign Exchange (FOREX) while capturing about 2.3% of the global coffee market. About 95% of Ethiopia's coffee is grown without fertilizers or pesticides. Pests are controlled through traditional farming practices such as inter-cropping, while green mulches are used to maintain fertility. As a result, this organically grown coffee brings higher prices for those officially certified farmers (Madeley, 2002)

(see Chapter 13, Section 13.13, TRADE NOT AID and Section 13.13.2, Transform Products Unique to Sub-Saharan Africa).

Nutrients and Legumes to Increase Agricultural Production in West Africa

In West Africa, farmers traditionally use the nitrogen fixing *Acacia albida*, along with cattle manure, burning and fallow to maintain soil productivity. In pre-colonial Senegal, it was considered a grievous crime punishable by death to cut down designated *Acacia (Faidherbia) albida* trees in agricultural fields, strategically placed to improve crop production (Samba, *pers. comm.*). In tropical West Africa, nitrogen and phosphorous tend to be limiting to agricultural production. Going from arid to humid regions, the concentrations of these parameters tend to increase. N-deficiency is more important in the dry zone, while P-deficiency is more important in the wetter zones. As rainfall increases, so does the production of vegetation/organic matter and thus the availability of nitrogen. However, in the higher rainfall areas, soils become more leached, more acidic and P-availability becomes more limited by iron, aluminum or manganese toxicity (Breman & van Reuler, 2002 *In: Vanlauwe, et al., 2002*) (see Section 5.5.2.3 Nutrients, pH, acidity and carrying capacity). This concurs with Dusal (2002 *In: Vanlauwe, et al., 2002*) who states that the use of phosphate rock (PR) outside the acid soils of humid and moist sub-humid zones (where nitrogen is abundant) of Africa will have little impact due to nitrogen limitations.

N-deficiency is such a widespread problem that legumes, which fix nitrogen, could be useful almost everywhere in West Africa, nitrogen deficiency being more of a severe bottleneck/limiting factor to production than is the low availability of phosphorous in the soils. As a result, the contribution of legumes to the annual production of the herb layer of natural vegetation and rangelands is only about 5% (Breman & van Reuler, 2002 *In: Vanlauwe, et al., 2002*).

Legumes can partially satisfy the requirements of non-nitrogen fixing crops, the theoretical maximum being 50% (Breman & van Reuler, 2002 *In: Vanlauwe, et al.*, 2002).

The *tapades*⁹⁴ of Guinea-Conakry use green manure. In West and Central Africa, improved fallow management and the use of leguminous cover crops, mulches (live or dead) or agro-forestry species show a lot of promise. One major success is the use of *Mucuna* (leguminous cover plant) in southern Benin for the suppression of the pest *Imperata* (spear grass) and to improve soil fertility. Other examples are the use of pigeon peas, *Cajanus cajan*, in fallows and short rotation fallows with cowpea, *Vigna unguiculata*, in the dry savanna. Getting improved on-farm tested technology adopted by farmers is a key to productivity improvement and better NRM (Natural Resources Management) (IFAD, 2001). Leguminous groundnuts, common in West Africa are another example.

Biophysical limitations to this are 1) leguminous fallows do not work well in shallow soils and have not been adequately tested in poorly drained or Vertisols and 2) there are no leguminous fallow species or an analogue of *Tithonia rotundifolia* (Mexican sunflower)⁹⁵ that can replenish nitrogen fertility in semi-

⁹⁴ See Section 5.9.3.2, Loss of fallow turning wildlife into a short-term resource, Fouta Djallon Mountains, Guinea-Conakry, describing gardens around the house where women grow the bulk of vegetables.

⁹⁵ *Tithonia spp.* is used in the humid and sub-humid tropics of Sub-Saharan Africa at elevations of 500-2,000 m. Small-scale farmers in Kenya, Uganda, Tanzania, Zimbabwe, Malawi and Mozambique have adopted technology packages combining *Tithonia*, phosphate rock and leguminous (nitrogen fixing) fallows. The leaves are extremely high in nutrients. In western Kenya, analysis of nutrients as a % of dry matter in green leaves was found to be on the order of 3.5-4% nitrogen (N), 0.35-0.38% phosphorus (P), 0.59% calcium (Ca) and 0.27% magnesium (Mg). This richness in nutrients is believed to be due to deep roots and the secretion of citric acid to its rhizosphere (area of soil immediately around a plant's roots) solubilizing some soil nutrients. *Tithonia* is typically mixed with other hedge species along farm boundaries (Sanchez & Jama, 2002 *In: Vanlauwe, et al.*, 2002). The leaves of *Tithonia* are used as green manure (Jama, Palm, Bruesh, Niang, Gachengo, Nziguheba & Amadalo, 2000). *Tithonia* biomass has been shown to double maize yields without application of mineral fertilizers. It represents a redistribution of nutrients from within the farm as opposed to an introduction from outside, meaning that

arid areas (e.g., the Sahel) (Sanchez & Jama, 2002 *In: Vanlauwe, et al.*, 2002). Thus, these techniques are best used in the sub-humid well-drained “red soils” of East and Southern Africa and should work in the sub-humid areas of West Africa (Sanchez & Jama, 2002 *In: Vanlauwe, et al.*, 2002). However, as discussed, *Acacia albida* appears to have similar qualities (Franklin, Martin & Sherman, 1992; Winrock International, 1995) and is useful in the drier Sahelian soils.

For instance, in the savanna zone of West Africa with low rainfall (500 - 1000 mm annually), base leaching is limited; hence soils have a relatively high pH (pH 6.0 to 6.5). However, soil acidity may rapidly increase with farmers’ cultural practices, such as reduced fallow due to population growth, intensive cropping, nutrient losses by erosion and runoff, and cations Ca^{2+} and Mg^{2+} losses associated with nitrate leaching. Thus, acidification of cultivated soils and P-deficiency due to high P-fixation could adversely affect crop yields.

“Considering P deficiency and soil acidification induced by farmers’ practices, organic amendments, rock phosphates and dolomite are interesting alternatives that could be exploited to improve traditional farming system productivity in Sub-Saharan Africa” (Bado, Sedogo & Lombo, 2004 *In: Bationo, 2004*).

Experiments in Ghana and Niger have demonstrated that by increasing the longevity and productivity of suitable agricultural land, the application of inorganic and organic fertilizer reduces the need to cultivate unsustainable and fragile marginal lands (Vlek, 1993 *In: Gruhn, et al.*, 2000). The extension of LEI/INM techniques to small-scale farmers may be critical in helping to stem the tide of expansion onto marginal land such as critical wildlife and livestock habitat, and as a result may help minimize the growing conflicts between pastoralists and small-scale farmers across the subcontinent.

eventually, as crops such as maize absorb these nutrients, external inputs would be required (Sanchez & Jama, 2002 *In: Vanlauwe, et al.*, 2002).

Mitigation of Nutrient Mining in the Groundnut Basin of Senegambia, West Africa

The Groundnut Basin of Senegal (Gambia being an extension) has not benefited from the Green Revolution as much as regions well endowed with water resources. The zone occupies 65,000 km² (1/3 or 33% of the country's area) and is one the most important agricultural regions of Senegal (71% of the total crop production). At similar Sudanian (600-800 mm rainfall) sites in Kaolack, Senegal and the Gambia, the loss of nutrients through nutrient mining is continuing. Technologies that result in greater yields without being "nutrient balance positive" only exacerbate the problem. The loss of soil organic matter, a property critical to fertility, water-holding capacity, microorganism livelihood, and to the moderation of temperature extremes, continues unresolved. Possibilities of using indigenous vegetation to restore soil fertility are promising, but have not been examined in realistic situations. Virtually all studies done in West Africa have shown that the factor most commonly limiting grain production is the supply of phosphorus. A combination of animal manure and inorganic nitrogen can lead to yield increases that are sustained longer than the use of inorganic nitrogen alone. Rotation of crop legumes with cereals can also significantly increase cereal production (InterCRSP, 1997).

On a pilot farm in Senegal and believed to be typical of the region, estimates of food sufficiency (millet as the staple) for the village are that only 20% of the households are likely to be food-sufficient, the remainder relying on imports. Food can be deficient for periods as long as seven months. Decline in crop fertility over the last five years is attributed to low fertility of soils, decline in rainfall, invasion of cropland by parasitic weeds (*Striga*) and the lack of fertilizers, wind and rain erosion, and elimination of fallow. Crop responses to

inputs such as fertilizers are generally low and unprofitable for the farmer
(InterCRSP, 1997).

“In the southeastern Peanut Basin (Groundnut Basin) of Senegal millet grown with manure continues to be 12% more profitable than millet grown with recommended doses of fertilizer and 58% more profitable than millet grown without fertilizer. In the central Peanut Basin, millet grown with manure continues to be 36% more profitable than millet grown with fertilizer and 43% more profitable than millet grown with no fertilizer. Unfortunately, manure is extremely limited and the somewhat greater profitability of the fertilizer technology over the non-fertilizer technology (36% in the southeast and 5% in the center) does not appear to provide adequate incentive for farmers to use fertilizer in the risky Sahelian environment” (Diagana & Kelly, 1996).

Farmers cope through youth labor migrations to urban centers, and thus remittances. Increases in crop yields may be obtained from a sequential application with rock phosphate applied to the very acid soils (e.g., pH<5.5), and phosphogypsum - a by-product of phosphate mining also containing calcium and sulphur, applied to those soils with higher pH, to the drier soils, and to those with lesser soil P buffering capacity. Crop residues are all used for feeding animals and nothing is available to restore soil organic matter. Farmers usually leave *Cordyla pinnata* and *Piliostigma thonningii*, which are leguminous shrubs/trees in the crop fields. The density can reach 600 to 700 shoots/ha (InterCRSP, 1997).

In the Gambia, fallow land has disappeared resulting in a loss of soil structure and causing reduced infiltration and increased runoff. Harvest of groundnuts disturbs the soils, the “hay” being used for forage, leaving bare ground susceptible to wind and water erosion. More fields were observed with purple (witchweed) striga (*Striga hermonthica*) flowers in this area than anywhere on the survey, suggesting as an indicator species that these soils were exhausted and severely mined of nutrients and probably very acid. Trials are being run comparing the effects of

two sources of manure (cow and horse dung) and different levels of phosphorus, alone or combined with the cropping system (peanut/millet) (InterCRSP, 1997).

In 1996, following the World Food Summit, a consortium of seven research institutions launched a Soil Fertility Initiative (SFI) for Sub-Saharan Africa: 1) UN Food and Agricultural Organization (FAO), 2) the International Centre for Research in Agroforestry (ICRAF), 3) the International Fertilizer Industry Association (IFA), 4) the International Fertilizer Development Centre, 5) the International Food Policy Research Institute (IFPRI), 6) U.S. Agency for International Development (USAID) and 7) the World Bank. The SFI will look at not only nutrient replenishment, but the overall biological and physical characteristics which determine the ability of the soils to supply water to the plants, the interaction with soil fertility to other inputs, the economic feasibility (often the major constraint) to improved practices, and the availability and accessibility of sources of plant nutrients (Dudal, 2002 *In: Vanlauwe, et al.*, 2002).

Integrated Nutrient Management (INM)/Low External Input (LEI) Agriculture in East and Southern Africa

The combined nitrogen fixation with leguminous plants (e.g., *Sesbania sesban*, *Tephrosia spp.*, *Crotalaria spp.*, *Gliricidia sepium*, and *Cajanus cajan*/pigeon pea) during fallow periods of two to three years to supply nitrogen, combined with locally produced phosphate rock (PR – as an alternative to expensive imported super phosphate fertilizers that are only affordable to small-scale farmers if subsidized) and shrubs of the *Tithonia rotundifolia* (Mexican sunflower) and *Lantana camara*, whose leaves provided nitrogen, phosphorus, potassium, calcium and magnesium, resulted in increases from two to six times the normal 1 ton/ha yield of maize.

“Pigeon pea root exudates have been found to contain phenolic compounds (e.g. piscidic acid), which chelate Fe (iron)⁹⁶ to free P in Fe bound P in soils for crop uptake. It is also reported that pigeon pea root exudates dissolve phosphate-containing rocks (e.g. phosphate rocks) to make P available for crop use” (Yeboah, Fening & Ampontuah, 2004 *In:* Bationo, 2004).

It is estimated that tens of thousands of small-scale farmers in Kenya, Uganda, Tanzania, Zambia, Malawi, Mozambique and Zimbabwe are adapting this form of soil enrichment (Sanchez & Jama, 2002 *In:* Vanlauwe, *et al.*, 2002). In Zambia, improved fallow technology using:

“sesbania and pigeon pea have a potential to supply inorganic soil nitrogen through leafy biomass and litter. The nitrogen contribution of sesbania and pigeon pea fallows to subsequent crop was evidenced by increased maize yields after these fallows as compared to no tree treatments. Improved fallows have the potential of improving soil physical conditions as compared to maize mono-cropping systems as shown from high soil aggregation, greater water infiltration, higher soil water sorptivity and reduced resistance to penetration” (Chirwam, *et al.*, 2004 *In:* Bationo, 2004).

IFAD (2002) has identified technologies that focus on improved management of natural resources, particularly water and soil, and are, by and large, not input intensive (e.g., capital intensive):

- **Bana Grass** (*Pennisetum sp.*), grown on contour ridges, to prevent soil erosion and provide fodder for animals;

⁹⁶ Also called sequester, a process of binding heavy metals that prevents heavy metals from combining with other elements, thus freeing up nutrients such as phosphorus either in the plant and/or the soil for plant production

- **Cowpeas** (*Vigna unguiculata*), grown in association with maize, as a food-security crop, to fix nitrogen and, through improved ground coverage, reduce weed growth and soil erosion;
- **Alternative Tillage Techniques** to reduce erosion, improve water retention and, in some cases, reduce labor and draft-power requirements (tied ridging, minimum tillage, etc.);
- **Production and Utilization of Drought-Resistant Food-Security Crops** – cassava and sweet potatoes – in association with pigeon peas as a food, cash and fodder crop to increase soil fertility (none of which are widely grown in Zimbabwe);
- **Live Fencing**, to reduce deforestation, degradation of communal lands, and labor requirements and to improve livestock management;
- **Use and Appropriate Application of Manure and Ant (Termite) Heaps** to improve soil fertility and structure; and
- **Improved Dambo (Low Lying Wetlands) Management**, to reduce soil erosion, increase water retention, control grazing, and thus permit intensified and sustainable production.

5.12.1.2 Green Revolution technologies

It took nearly 1,000 years for wheat yields to increase from 0.5 to two metric tons/ha, but only 40 years to climb from two to six metric tons/ha. A 1967 report of the U.S. President's Science Advisory Committee concluded that “ ‘the scale, severity and duration of the world food problem are so great that a massive, long-range, innovative effort unprecedented in human history will be required to master it’ ” (IFPRI, 2002). The Rockefeller⁹⁷ and Ford⁹⁸ foundations established

⁹⁷ The Rockefeller Foundation, 420 Fifth Avenue New York, NY 10018, Tel: 212.869.8500, www.rockfound.org

an international agricultural research system to transfer and adapt scientific advances to developing countries. In 1968, U.S. Agency for International Development (USAID) Administrator William S. Gaud coined the term “Green Revolution” to describe this phenomenal growth in agriculture (IFPRI, 2002).

To achieve higher yields for rice and wheat, scientists needed to develop plants that were more responsive to plant nutrients, had shorter, stiffer straw to support the weight of heavier heads of grain, and that could mature quicker and grow at any time of the year permitting farmers to grow more crops each year on the same land. The International Rice Research Institute (IRRI) in the Philippines developed semi-dwarf varieties of rice, while Norman Borlaug, “father of the Green Revolution”, developed new varieties of wheat. High-Yielding Varieties (HYVs) have since been developed for sorghum, millet, maize, cassava and beans (IFPRI, 2002).

“Green Revolution” technology relies on high input/high output technologies such as irrigation, fertilizers and genetically modified seeds. This often relies on heavy subsidies, many of which have fallen away, as discussed, with World Bank IMF structural adjustment policies (SAPs). There are often major environmental costs to increasing food production through intensification (e.g., reduced fallow, double cropping, irrigation – soil salinization, intensive use of fertilizers, adverse impact on soil structure and chemistry, pesticides – pest resistance, and environmental pollution) (Maxwell, 2001 *In: Devereux & Maxwell, 2001a*).

Agricultural crossbreeding has been implemented since about 8,000 BC. Today, 34% of American corn is genetically modified (GM), as are 78% of U.S. soybeans. Some 3,500 international scientists, including 20 Nobel laureates, have

⁹⁸ Ford Foundation, Headquarters), 320 East 43rd Street, New York, NY 10017 USA,
Tel: (212) 573-5000 , fax: (212) 351-3677, www.fordfound.org, office-of-communications@fordfound.org

signed the AgBio World Foundation's "Declaration of Support for Agricultural Biotechnology" (Murdock, 2003). American researchers such as Chassy (2002) and Harlander (2002) believe that research has shown genetically modified crops to be safe, something that has not been demonstrated with traditional crops. Yet GM crops remain controversial and emotive.

Almost all of the world's major crops are now being improved using genetic engineering, although initial efforts have focused on commodity crops — primarily corn, soybeans, cotton, canola and potatoes. However, there are many other crops, including other cereal grains and a number of vegetables and fruits that have been improved using genetic engineering and are in the commercialization pipeline (Harlander, 2002).

Genetic Research

Norman Borlaug (2002) has noted a need for research to work with improving yields from indigenous crops. Borlaug (2002), working with groups like the Sasakawa Foundation, is developing improved technology for basic food crops: maize, sorghum, wheat, cassava, rice, and grain legumes. Researchers at Purdue University in the USA are working with high-yielding sorghum varieties and hybrids with resistance to the heretofore-uncontrollable parasitic weed, *Striga spp.* Cereal varieties are being developed with greater tolerance for soil alkalinity, free soluble aluminum and iron toxicities. These varieties help to ameliorate the soil degradation problems that have developed in many existing irrigation systems. They also have allowed agriculture to succeed in tens of millions of hectares with highly leached acid soils.

Genetic engineering offers the potential for plants themselves to generate some of the nutrients they require through nitrogen fixation. In this process, rhizobium

bacteria infect, invade, and draw energy from leguminous plants, and in return the bacteria convert and store atmospheric nitrogen in a form that the plant can use for growth (Rao, 1993 *In: Gruhn, et al.*, 2000).

The Downside of the Green Revolution

The negatives are many, the question being whether the benefits outweigh the costs?

A major shortcoming of the “Green Revolution”, over a large part of soil moisture and water limited Sub-Saharan Africa, is that it is heavily dependent upon irrigation (potential of 42.5 million ha for all of Africa, (see Table 5.29: Environmental impact assessment of irrigation, by basin in Africa) and high-potential rainfed areas (27% of Sub-Saharan Africa \approx 600 million ha). Sub-Saharan Africa has yet to experience a “Green Revolution” (IFPRI, 2002).

IFPRI (2002) also states that while small-scale farmers initially lagged behind large farmers in adopting “Green Revolution” technologies, many of them eventually did so.

“Many of these small-farm adopters benefited from increased production, greater employment opportunities, and higher wages in the agricultural and non-farm sectors. Moreover, most smallholders were able to keep their land and experienced significant increases in total production. In some cases, small-scale farmers and landless laborers actually ended up gaining proportionally more income than larger farmers, resulting in a net improvement in the distribution of village income...The Green Revolution has also been widely criticized for causing environmental damage. Excessive and inappropriate use of fertilizers and pesticides has polluted waterways, poisoned agricultural workers, and killed beneficial insects and other wildlife. Irrigation practices have led to salt build-up and eventual

abandonment of some of the best farming lands. Groundwater levels are retreating in areas where more water is being pumped for irrigation than can be replenished by the rains. And heavy dependence on a few major cereal varieties has led to loss of biodiversity on farms" (IFPRI, 2002).

IFPRI (2002) argues that much of this environmental degradation can be linked to inadequate agricultural extension to illiterate farmers on the appropriate use of technologies, and subsidies that encourage the overuse of "cheap" inputs. The authors would argue that subsidies to support agricultural research and extension, as well as inputs may be required to maintain productivity and competitiveness (see Chapter 12). On the positive side they, note that more intensive farming using Green Revolution technologies has helped decrease the need to expand into forested lands and other fragile environments.

Brown (2003a) questions how much additional yield increases from GM crops can be expected,

"After climbing from 1.1 tons/ha in 1950 to 2.8 tons/ha in 2002, the world grain yield has reached a level where it is becoming more difficult to sustain a continuing rapid rise...At the center of the tripling of world grain production (1950-2000) during the last century were high-yielding varieties, the dwarf wheats and rices developed originally in Japan and hybrid corn from the United States. Under favorable conditions, these varieties could double, triple, even quadruple the yields of traditional varieties. But there are no new varieties in the pipeline that can lead to similar quantum jumps in yields. Nearly two decades have passed since the first genetically modified crop varieties were released, yet biotechnologists have yet to produce a single variety of wheat, rice, or corn that can dramatically raise yields (beyond what they already have). Nor does it seem likely that they will, simply because plant breeders, using conventional breeding techniques, have already taken most of the obvious measures to get the big jumps in yields.

Helping to realize the genetic potential of the new high-yield varieties was the growth in irrigation, which expanded from 94 million ha in 1950 to 272 million (ha) in 2000, raising the share of the world's grain harvest from irrigated land to 40%. Now growth in the irrigated area is slowing as many countries lose irrigation water from aquifer depletion and its diversion to cities.

As high-yielding varieties spread and irrigated area expanded, fertilizer use climbed from 14 million tons in 1950 to 137 million tons in 2000—a tenfold gain. While irrigation was removing the moisture constraints on crop yields, fertilizer was removing nutrient constraints. Then diminishing returns set in and the growth in fertilizer use slowed markedly.

...Much of the impressive gain in yields came as scientists boosted the share of photosynthate going to seed from 20% in traditional varieties to over 50% in modern high-yielding grains, close to the theoretical limit. Efforts to raise yields further are starting to push against the physiological limits of plants. In many countries, the rise in yields is slowing and in some it is leveling off.

The rise in grain yields will likely slow further during this decade. In addition to the shrinking backlog of technology to draw upon, many farmers also must deal with a loss of irrigation water, and farmers worldwide are facing the prospect of record-high temperatures—all of which could make it difficult to sustain a steady rise in land productivity. Although the rise in yields is slowing, there are still many opportunities for increasing yields, but in most situations the potential for doing so is modest”.

Eicher (1990 *In: Eicher & Staatz, 1990*) believes that there are political, scientific, technical and economic reasons that explain why it is proving difficult to develop new Green Revolution food crop technology that is high yielding, biologically stable and profitable for smallholders in Africa. To overcome these constraints will require: 1) strengthening national agricultural research systems supplementing Consultative Group on International Agricultural Research (CGIAR), 2) becoming more efficient at borrowing already existing technologies, and 3) CGIAR and donors devoting more attention to the scientific and

managerial capacity of national agricultural research systems. FAO (2002a) suggests that for a second Green Revolution, research must give priority

“...to the needs of the poor in the marginal, rainfed areas bypassed by the first Green Revolution”, something discouraged under IMF/World Bank Structural Adjustment Policies (SAPs) (see Chapter 12, Section 12.4.5, Decline in Research and Extension as a Result of Structural Adjustment).

Another problem is that the for-profit agro-industries who develop GM seeds very often use what is called “terminator” technology meaning that F1 (first) generation seeds must be bought each year in order to maintain high yields, as opposed to the farmer saving seeds from the F2 (second) generation and re-sowing them, thus engendering strong opposition by small-scale farmers. Also, concern has been raised that widespread mono-culture production of GM crops could result in the loss of local biodiversity/genetic varieties, and even result in genetic pollution with cross-breeding and the out-crossing of undesirable traits to the wild relatives of the GM crops (Paarlberg, 1999 *In:* Moorehead & Wolmer, 2001 *In:* Devereux & Maxwell, 2001a; Eicher, 1990 *In:* Eicher & Staatz, 1990; Eswaran, Arnold, Beinroth & Reich, 1999b *In:* Eswaran, *et al.*, 2003; Madeley, 2002), (see Chapter 12, Section 12.4.4.2, Impacts of structural adjustment on peasant production systems, impacts of structural adjustment on central Ghana cash crop economies, fallow and virgin forests).

Madeley (2002) raises concern of a few Transnational Corporations (TNCs) or – multi-nationals) with their GM patents “controlling the food chain”. Four multi-national biotech companies, DuPont, Syngenta, Monsanto and Mitsui own 44% of the patents for the world’s most important staple food crops of rice (613 patents), maize (999), wheat (1,495), soybean (750), potato (81) and sorghum (17) (Madeley, 2002). Concern also exists that this GM technology, requiring the use of expensive fertilizers and pesticides does not always result in higher yields,

especially in the marginal lands over much of Sub-Saharan Africa that have other constraints (e.g., soil moisture, soil acidity, etc. – see Section 5.5.2, Physical and Environmental Constraints to Overcoming Food Production in Sub-Saharan Africa), and thus are not only unaffordable but technologically inappropriate other than on prime agricultural lands run on a commercial basis. Hans Herren, Director-General of the International Centre of Insect Physiology and Ecology in Nairobi does not see GM crops making an impact on food production in Africa for the next 15-20 years (Madeley, 2002).

Few of the packages available from other parts of the world, including those for millet and sorghum, have been immediately suited to Sahelian growing conditions (Madeley, 2002). The Green Revolution also ignored traditional crops, the staples of poor farmers, leading to a movement away from the more appropriate, drought-resistant indigenous crops such as millet and sorghum to a maize mono-culture. This resulted in the growing concentration of ownership of land and resources in the hands of an elite and a focus on cash crops (Roman, 2003).

Green Revolution, Asia

As a result of the “Green Revolution”

“yields of rice and wheat virtually doubled. Higher yields and profitability also led farmers to increase the area of rice and wheat they grew at the expense of other crops. And with faster-growing varieties and irrigation, they grew more crops on their land each year. These changes more than doubled cereal production in Asia between 1970 and 1995, while population increased by 60%. Instead of widespread famine, cereal and calorie availability per person increased by nearly 30%, and wheat and rice became cheaper” (IFPRI, 2002).

“The Green Revolution led to sizable increases in returns to land, and hence raised farmers’ incomes. Moreover, with greater income to spend, new needs for farm inputs, and milling and marketing services, farm families led a general increase in demand for goods and services. This stimulated the rural non-farm economy, which in turn grew and generated significant new income and employment of its own. Real per capita incomes almost doubled in Asia between 1970 and 1995, and poverty declined from nearly three out of every five Asians in 1975 to less than one in three by 1995. The absolute number of poor people fell from 1.15 billion in 1975 to 825 million in 1995 despite a 60% increase in population...The Green Revolution also contributed to better nutrition by raising incomes and reducing prices, which permitted people to consume more calories and a more diversified diet. Big increases occurred in per capita consumption of vegetable oils, fruits, vegetables, and livestock products in Asia” (IFPRI, 2002).

Vandana Shiva,⁹⁹ an Indian scientist and activist, claims that the Green Revolution, despite giving more grain per unit, yields only 6 units of energy for every 15 expended in its production and requires a lot more water. The Green Revolution has left behind diseased and exhausted soils, pest-infested crops, waterlogged areas, deserts and indebted and impoverished farmers (Legum, 2002).

⁹⁹ Trained as a physicist and did her Ph.D. on the subject “Hidden Variables and Non-locality in Quantum Theory” from the University of Western Ontario. She later shifted to inter-disciplinary research in science, technology and environmental policy, which she carried out at the Indian Institute of Science and the Indian Institute of Management in Bangalore. In 1982, she founded an independent institute, the Research Foundation for Science, Technology and Ecology in Dehra Dun dedicated to high quality and independent research to address the most significant ecological and social issues of our times, in close partnership with local communities and social movements. In 1991, she founded *Navdanya*, a national movement to protect the diversity and integrity of living resources, especially native seeds. Dr. Shiva has contributed in fundamental ways to changing the practice and paradigms of agriculture and food. Her books, “The Violence of Green Revolution” and “Mono-cultures of the Mind” have become basic challenges to the dominant paradigm of non-sustainable, reductionist Green Revolution agriculture. Address: Director, Research Foundation for Science, Technology and Ecology A-60, Hauz Khas, New Delhi – 110 016 Tel: 91-11-26968077 & 26853772, Fax: 91-11-26856795 and 26562093 Email: vshiva@giasdl01.vsnl.net.in. Extracted from http://www.vshiva.net/vs_cv.htm, Short Curriculum Vitae of Dr. Vandana Shiva.

“The high yields of rice and wheat in India’s and Pakistan’s 1960s “Green Revolution” is near an end. High yielding varieties of hybrid rice and wheat depended on high and dependable applications of water, and high inputs of fertilizers and pesticides. However, since the 1970s the spread of irrigation has dramatically declined because the most fertile lands, the most accessible sources of waters and the best dam sites have already been developed, substantially raising the cost per hectare of new irrigation projects, which governments can no longer afford to subsidize as world agricultural prices have fallen” (McCully 2001).

At the beginning of the 20th century, India had 30,000 varieties of rice, while today 75% of the yield comes from just ten varieties (Madeley, 2002)

Green Revolution, Philippines

“Since the 1980s the yields of ‘Green Revolution’ rice on managed test plots at the Philippines International Rice Research Institute (IRRI) have been falling from 10 tons/ha in 1966 to less than 7 tons/ha in the late 1990s. The IRRI researchers believe decline attributable to degradation of paddy soils due to the switch from seasonally flooded rice to perennial irrigation with 2-3 crops/year. Year-round flooding may be killing essential soil microbes, reducing the ability of the soils to provide nutrients to the crops. Replacement of traditional manures with modern fertilizers may also be depleting essential trace elements in soil such as zinc and sulphur” (McCully, 2001).

The costly inputs of fertilizers and pesticides, along with irrigation to grow rice have “devastated the land and ruined the livelihoods of farmers”, with 48 of 54 provinces having depleted soils (Madeley, 2002). IRRI’s research depends on expensive chemical inputs, which the small-scale farmer cannot afford. They have demonstrated that adoption of integrated pest management (IPM) can help reduce the application of pesticides without affecting yields (Madeley, 2002).

Green Revolution, Zimbabwe

Two maize varieties account for 90% of the planted maize and have displaced more traditional varieties of millet and sorghum (Madeley, 2002). However, these varieties required subsidized seed, fertilizer and pesticides that ended with the adoption of structural adjustment policies (SAPs). This had an adverse impact on both production and the environment (see Chapter 12, Section 12.4.3.3, Impacts of structural adjustment on maize production and fertilizer use in Zambia and Zimbabwe).

Green Revolution, South Africa

Legum (2002) claims that a GM cottonseed sold by Monsanto in South Africa (S.A.), which incorporated the *Bacillus thuringiensis* (Bt) gene, was the first genetically modified crop grown in that country. Bt acts as a pesticide, and in 1998, over one season, Monsanto showed a 20-30% increase in yield by the best four small-scale farmers in the Makhatini district of KwaZulu Natal. The environmental NGO, Biowatch, in a 2000 analysis found (Legum, 2002):

- Pest outbreaks they had never before encountered so they still had to be sprayed over and above the cost of paying for the Bt gene. A key pest in South Africa's GM cotton, the stinkbug, was a problem in American trials, but this information was never provided to the farmers. In some cases, a high proportion of the crop was lost.
- Small-scale farmers had to sign license agreements, which they did not understand, making it illegal to store seeds or to exchange them with neighbors.

- According to the GMO act, farmers were held liable for any environmental or other damage as a result of planting the crops including genetic pollution.

According to Louw (*pers. comm.*) of Textile S.A., who is working with the 3,000 small-scale farmers who grow cotton, the latter did not realize that the “Bt Cotton” only protected against boreworms and that spraying for other pests was required. Cotton S.A. is working with small-scale farmers to expand their numbers and production, which is currently only 5% of South Africa’s cotton production, the remainder being produced by 300-400 commercial farmers, the numbers and production varying depending on the international price largely controlled by the USA (see Chapter 12, Section 12.2.4.4, Cotton subsidies and protected markets) compared to other commodities. South Africa imports about 50% of its cotton now. Nevertheless, GM crops such as corn are a key to food production in South Africa and will likely remain so.

Time will tell as to what degree the expensive “Green Revolution Technologies” will help Africa. GM technologies may prove useful if integrated into low-input low-cost technologies to lower costs of the Green Revolution.

5.12.1.3 Irrigation potential

“The soils of the ‘Green Revolution,’ which had supported traditional farming for hundreds of years, are becoming waterlogged and suffering from salinization from perennial irrigation. It is estimated that more land is being abandoned each year from soil salinization than new schemes coming on line” (McCully 2001).

In Sub-Saharan Africa in the 1980s, for every hectare brought under irrigation, another went out of production due to salinization and water logging (Madeley, 2002).

Currently, there are approximately 5.2 million ha in irrigation in Sub-Saharan Africa (Table 5.28) using only 2% of the renewable water supplies (FAO, 2002a). FAO's definition of irrigation includes traditional floodplain recession agriculture, "data on irrigation relate to areas equipped to provide water to the crops. These include areas equipped for full and partial control irrigation, spate irrigation areas, and equipped wetland or inland valley bottoms" (FAOSTAT, 2004).

Table 5.28: Actual irrigation in Africa and Sub-Saharan Africa

Irrigation	Year	1961	1971	1981	1991	2002
Agricultural Area (1000 Ha)						
Africa		7,410	8,609	9,631	11,351	12,879
Africa South of Sahara		2,709	3,171	4,064	4,883	5,225

Note: Includes islands of Madagascar, Mauritius and Sao Tome and Principe for both Africa and Sub-Saharan Africa
Source: FAOSTAT (2004)

If one discounts Madagascar with 1,090,000 ha and Sudan 1,950,000 ha in irrigation (FAOSTAT, 2004) only 2,185,000 ha was irrigated on the rest of the subcontinent in 2002.

The potential for irrigation along with "environmental constraints" is 42.5 million ha for all of Africa (FAO, 1997d) (Table 5.29) or about 30,770,000 ha¹⁰⁰ for Sub-Saharan Africa. Alemayehu (2000) estimates an irrigation potential of 33.6 million ha in Sub-Saharan Africa.

FAO (1997b *In:* Barbier, 1998) estimates that 6% (11,580,000 ha) of Africa's 1995 cropland under cultivation (193 million ha) was under irrigation (Table 5.16). NEPAD (2002) estimates the percentage of arable¹⁰¹ land in Africa that is irrigated to be 7%, amounting to 12,879,000 ha in 2002 (Table 5.28). NEPAD (2002) estimates that barely 3.7% or about 5.2 million ha of arable land was under irrigation in Sub-Saharan Africa as noted by FAOSTAT (2004) (Table 5.28). Alemayehu (2000) estimates that about 5.3 million ha were under irrigation in Sub-Saharan Africa in 1982 of which 2.7 million ha were small-scale "traditional" irrigation. That would imply about nearly half being linked to "traditional floodplain recession agriculture" that is often considered as a form of irrigation and/or mini-barrage schemes for small-scale farmers, as is described in Chapter 7 on dams.

Similarly, according to McCully (2001), FAO estimates that nearly 50% of the 5 million ha irrigated in Sub-Saharan Africa receives water from small-scale and traditional systems. This implies that the 2,185,000 ha irrigated on the rest of the subcontinent in 2002, discounting Sudan and Madagascar, is mostly small-scale and traditional, likely a large part on traditional floodplain systems (recession agriculture as discussed in Chapter 7).

NEPAD (2002) provides slightly different figures for the rest of the world; the corresponding percentages are 10%, 29% and 41% of the arable land that is irrigated for South America, East and Southeast Asia and South Asia respectively compared to Table 5.16.

¹⁰¹ Arable Land "is land under temporary crops (double-cropped areas are counted only once), temporary meadows for mowing or pasture, land under market and kitchen gardens and land temporarily fallow (less than five years). The abandoned land resulting from shifting cultivation is not included in this category. Data for "Arable land" are not meant to indicate the amount of land that is potentially cultivable (FAOSTAT, 2004). FAO helped put together the NEPAD report.

In Africa as a whole, in the absence of deliberate steps to accelerate progress, the amount of irrigated land is expected to grow at under 1%¹⁰² over the period from 1995/97 to 2030, at which time the amount of irrigated land would be barely 20% of the potential in Sub-Saharan Africa (NEPAD, 2002). FAO (2002a) sees a potential to increase land under irrigation by an additional 2 million ha by 2030, an annual growth rate of about 1.1% assuming irrigation climbs from the existing 5 to 7 million ha. If 7 million ha is 20% of the irrigation potential, this implies an irrigation potential of about 35 million ha for Sub-Saharan Africa, similar to the estimate of 33.6 million ha given by Alemayehu (2000). Looking towards the Year 2010, in Sub-Saharan Africa, the relative contribution of irrigated cereal production could rise from 11% of food demand and 9% of total cereal utilization to 13% of food demand and 11% of total utilization. Cereal output from irrigation in Sub-Saharan Africa has the possibility to triple from 4.6 to 15 million tons (Nana-Sinkam, 1995). However, a Stanford University study in the early 1980s (Pearson, Stryker & Humphreys, 1981 *In:* University of Michigan, 1985a) raised serious questions over the viability of existing irrigated rice schemes in West Africa, finding only Mali and Sierra Leone as having the potential to produce rice cheaper than imports.

Major environmental constraints to irrigation, which are discussed in more detail in Chapter 7 on dams, are the problems associated with irrigation requiring exorbitant costs of mitigating salinization (e.g., tile and drainage fields), as well as artificial flooding to maintain traditional floodplain ecosystems for food production and biodiversity. Also irrigation can result in both internal and cross border conflicts (see Chapter 7, Section 7.9.3.1, Senegal River and Chapter 13, Section 13.11, AFRICA'S POTENTIAL WATER WARS), where water in much

¹⁰² This is believed to be 1%/year since the NEPAD report was put together by FAO and the FAO (2002) projected increase in irrigation by an additional 2 million ha, below, amounts to a 1.1%/year increase. Use compound interest formula: Future Value = Present Value (1 + growth rate)ⁿ where growth rate expressed as %/100 and n = period in years. Can also be used to estimate population growth rates of people and wildlife,

of Africa is limiting. Its use and allocation will require careful planning especially where rivers cross many borders such as the Nile, Niger, Senegal, Gambia, Zambezi and Limpopo Rivers.

Many of Africa's riverine systems are floodplain ecosystems in which rural communities have traditionally survived from a diverse array of resources coming off these floodplains including recession agriculture, dry season forage for livestock, wildlife, fresh and estuarine fisheries, waterfowl, etc. Modern irrigation is often based upon large dams and flow regulation that have disrupted these traditional life cycles by eliminating or greatly reducing the magnitude and/or duration of flooding in favor of man-made irrigation schemes (see Chapter 7, Section 7.8.1, Dam Impacts on Floodplains & Section 7.9.1.1, Senegal River). It is not evident that the yields from these man-made schemes are more cost-effective than helping rural communities sustainably manage these traditional floodplain systems. In addition, rural communities tend to be displaced by multi-nationals and national elites (bureaucrats and small traders) in the take-over of modern irrigation systems (see Chapter 7, Section 7.9.3.1, Senegal River & Section 7.9.5.1, Senegal River). Thus, they lose their traditional systems, while lacking access to the modern systems, usually due to being under-capitalized and lacking the technological skills to sustainably manage these intensive irrigation systems (Madeley, 2002). Because of the diverse array of resources taken from Sub-Saharan Africa floodplains, in many instances the loss of these traditional resources, in place of mono-culture such as rice, can result in malnutrition (see Chapter 7, Section 7.9.8.1, Senegal River). For example,

“there is growing evidence that large-scale capital intensive water development schemes do provide neither the range of foodstuffs nor the economic return of traditional systems. Studies, comparing the efficiency per unit of water of traditional extensive systems of cultivation, grazing and fishing in the Niger Inner Delta (a traditional floodplain ecosystem) with the intensive modern project

of the Office du Niger, showed that both systems produce about the same gross profit margin,¹⁰³ even when the running costs and management charges for the irrigation scheme are taken into account. However, the extensive system produces meat, milk, fish and rice compared to the rice-only irrigated system. More importantly, when the interest charges arising from the irrigation scheme are taken into account, the net profit from the irrigated rice turns into a loss of \$US 0.65/100 m³ of water, whilst the extensive traditional methods benefit from the 'free services of nature' and turn in a net profit of US\$ 0.42/100 m³ at 1984/85 prices" (FAO, 1997d).

In theory, dams with controlled releases could provide both modern irrigation while maintaining traditional floodplain systems. Hydrologists can easily model these events, but in practice, this mitigation tends to be ignored in favor of using water for other purposes (e.g., electricity) – see Chapter 7. The net result is that very often the rural poor are actually nutritionally and economically worse off from large-scale irrigation schemes. NEPAD's (2002) goals for irrigation

"required for land and water development until 2015 into: 1) small-scale irrigation developments, including small-scale informal irrigation, humid lowland developments, as well as land improvement activities (14.2 million ha), 2) upgrading and rehabilitation of existing large-scale irrigation systems (3.6 million ha), and 3) development of new, large-scale schemes (1.9 million ha)".

As noted the major emphasis will be placed on small scale irrigation (see discussion below).

Irrigation Technologies

The current strong interest in irrigation in Africa arises from the growing incapacity of much of the continent to feed itself. Food production, predominantly

¹⁰³ (Net Profit To Company/Gross Profit) x 100

under rainfed conditions, has risen at a rate of only 1.4% per annum in the period 1970 to 1990, less than half the rate of population growth that is estimated at 3.0% per annum. Recurrent droughts have accelerated the rising trend of cereal imports, which amounted to 28 million tons in 1984 and 31 million tons in 1992 (see Table 5.4) (Nana-Sinkam, 1995).

Botswana, Burkina Faso, Kenya, Mali, Mauritania, Niger, Senegal and Somalia contain some 11% of Africa's population. Their lack of rainfed potential and/or rising demographic pressure on rainfed land, are likely to make irrigation an essential element of future food strategies in the short and medium term. Eventually, some large-scale schemes may be justified in these countries, but there is a need to take advantage first of the scope for cheap rehabilitation wherever possible and, in some cases, expand existing schemes. Simple improvements to traditional swamp and flood irrigation, although giving smaller yield gains, could in aggregate also make an appreciable contribution to food supply (Nana-Sinkam, 1995).

Another 14 countries in Sub-Saharan Africa have some of their territory in drought-risk zones where small-scale irrigation based mainly on small dams (mini-barrages), direct pumping from rivers and groundwater could do much to reduce rural hardship and the need for costly disaster relief (Nana-Sinkam, 1995).

For the remaining countries in Sub-Saharan African, first priority is more likely to be given to rainfed development, which is usually simpler to organize, cheaper and can give quicker benefits. Nevertheless, few of these countries can afford to discard any existing schemes where rehabilitation is feasible, and in most there is scope for improvement and possibly expansion of traditional and small-scale irrigation (Nana-Sinkam, 1995).

Traditional Irrigation Sub-Saharan Africa

Traditional floodplain (recession agriculture) and swamp irrigation is practiced across Africa, some of the better-known systems being the Inland Delta of Niger in Mali, along the Senegal, Gambia, Pongola (South Africa) and Zambezi (Delta of Mozambique) Rivers. The *shaduf*-type irrigation also exists around oases. Ground water is used in other traditional systems for fruit and vegetable production where ground water is close to the surface and markets are available (Moore, *et al.*, 2000). Likewise, in the highlands of Tanzania (Kjekshus, 1977) and Kenya, traditional gravity-fed irrigation systems have existed for centuries. Improving these systems may be just as important as modern high-tech irrigation in assuring increased food security in rural Africa (Madeley, 2002).

Small-Scale Versus Large-Scale Irrigation

René Dumont (1966), in his work, is a proponent of small-scale peasant controlled irrigation over large-scale inefficient state run irrigation that often favors the elite, and even did do back in the 1960s. He cites the example of large scale irrigation of the overly-bureaucratic Niger Office (*Office du Niger*), providing a small 6.5% return on investment, where 33.3% would be required to demonstrate economic viability along the Inner Niger Delta. This compares favorably to the experience of failed large-scale irrigation schemes of SAED (*Société d'Aménagement et d'Exploitation des terres du Delta du Fleuve Sénégal*) along the Senegal River (see Section 5.6.3.2, Foreign assistance in Sahel goes for large scale as opposed to improving traditional agriculture, Irrigation Along the Senegal River; Chapter 7, Section 7.9.5.1, Senegal River and Section 7.9.7.1, Senegal River and Chapter 12, Section 12.4.4.1, Impacts of structural adjustment on peasant farmers along the Senegal River for detailed discussions on development impacts on traditional agro-pastoral systems in the Senegal River

Basin). By 1961, the *Office du Niger* project was producing only 1,000 tons of the originally projected target of 300,000 tons of irrigated cotton and food. Farmers and laborers from the more productive south were recruited disrupting families and entire societies. At the same time, logging and forest clearing in Upper Guinea, the source of the Niger River, was resulting in less transpiration and less rainfall. In 1973, the Niger failed to flow. In 1984, its flow was the lowest in a century, though floods returned in 1985 (Rosenblum & Williamson, 1987). This deforestation has continued in the Guinea-Conakry Highlands, threatening the long-term flows and hydrological regimes¹⁰⁴ of not only the Niger, but Senegal and Gambia Rivers among others (see Section 5.9.3.2, Loss of fallow turning wildlife into a short-term resource, Fouta Djallon Mountains, Guinea-Conakry).

René Dumont (*In:* Rosenblum & Williamson, 1987) in his book “A Very Bad Finish” written in 1987 at age 82 suggests that the for the same money that financed the failed dams and large-scale irrigation schemes on the Senegal River (see Chapter 7), 200 small dams and hand tools could have brought 40,000 villages to life from Senegal to Chad.

As is seen in Chapter 7, dams on the Senegal were not about helping Africa to develop but about Western consulting and construction firms getting rich or as Dumont says,

“ ‘has enriched foreigners, entrenched corrupt states and alienated peasants’ ” (René Dumont *In:* Rosenblum & Williamson, 1987).

In the Gambia River Basin, mini-barrages for local irrigation were strongly considered (Chapter 7, Section 7.7.5, Politics of Proposed Dams on the Gambia

¹⁰⁴ Risk of increased flows and flooding in rainy season, and reduced flows in dry season from decreasing water retention due to vegetation removal.

River, Section 7.9.5.2, Gambia River and Section 7.11, ALTERNATIVES TO LARGE DAMS).

Major Constraints to Irrigation as an Alternative to Production

There are many lessons for Sub-Saharan Africa, as it turns to irrigation to help solve its food problems. 2003 was the International Year of Freshwater. Irrigation - made possible through a network of canals, wells, dams and reservoirs – is responsible for the production of 40% of the world's food supply. Irrigation has also boosted crop yields and opened up new lands for farming. However while, we live on a water-rich planet, fresh water is not evenly distributed. This is resulting in more and more farmers - especially in regions of the world dependent on irrigation for food - coming up dry. China, India, Pakistan and the USA are the top four irrigators in the world (VOA, 2003).

Each of those three Asian countries has serious water problems in each of its major zones of irrigated agriculture: 1) rivers running dry, 2) ground water over-pumped extensively in order to meet demands for food production, thereby disrupting the natural hydrologic cycle, causing rivers and wetlands to dry up, the ground to collapse and fish, wildlife and trees to die and 3) soils becoming salinized. Salt is building up in the soil as a result of irrigation practices in a dry climate, making the cost of irrigation very high. If irrigation is to be sustainable, it will require construction of expensive subsurface drainage systems (VOA, 2003).

The collapse of many ancient desert-based and irrigation dependent civilizations [e.g., Mesopotamia (Iraq) and the Hohokam of central Arizona] is linked to soil salinization from irrigation. Only irrigation dependent Egypt avoided such catastrophes due to the cleansing of the annual Nile floods, that is until the

construction of the Aswan dams and now it too is faced with major soil salinization problems among others (Reisner, 1986; Ward, 2002).

In Pakistan, the Indus River and its 57,960 km (36,000 mi) of canal and 89,000 local watercourses – with a length of over 1.6 million km (million mi) in total – irrigate over 14.2 million ha (35 million acres) of land. However, as early as the 1960s, it was losing 40,485 ha (100,000 acres) of farmland/year from water logging and salinization (Ward, 2002). In Senegal, the cost of mitigating these two parameters puts the cost of irrigation perimeter construction at \$25,000-40,000/ha (Bosshard, 1999) (see Section 5.6.3.2, Foreign assistance in Sahel goes for large scale as opposed to improving traditional agriculture, Irrigation Along the Senegal River; Chapter 7, Section 7.9.6.1, Senegal River and Chapter 12, Section 12.4.4.1, Impacts of structural adjustment on peasant farmers along the Senegal River). It is estimated that about one out of every five ha of irrigated land worldwide is suffering in some degree from the build-up of salt in the soil. Thus, the challenge of better soil and water management is to try and reduce this problem and keep that land productive (VOA, 2003).

“This generation of farmers is also the first to face widespread aquifer depletion due in part to the use of powerful diesel and electric pumps that have become widely available only in the last few decades. Prospects for the big-three grain producers—China, India, and the United States, which account for nearly half of the world's grain harvest—show the potential consequences of future water shortages...Under the North China Plain, which produces half of China's wheat and a third of its corn, water tables are falling up to 3 meters per year. A World Bank assessment of China's water situation says, ‘Anecdotal evidence suggests that deep wells [drilled] around Beijing now have to reach 1,000 meters [more than half a mile] to tap fresh water, adding dramatically to the cost of supply’...In unusually strong language for a Bank report, it foresees ‘catastrophic consequences for future generations’ unless water use and supply can quickly be brought back into balance. In India, water tables are falling throughout most of the country. As a

result, thousands of wells are going dry each year" (Brown, 2003b).

In the United States, the USDA reports that in parts of Texas, Oklahoma, and Kansas—three leading grain-producing states—the underground water table has dropped by more than 30 meters (100 feet). As a result, wells have gone dry on thousands of farms in the southern Great Plains (Brown, 2003a; 2003b). The Ogallala Aquifer, which stretches from South Dakota to Texas in the USA, is being mined faster than it can be replenished. Use of these waters resulted in one of the most profound changes by humans in North America, turning short grass plains on which buffalo once roamed into a breadbasket of grain production. By 1977, waters from the Ogallala Aquifer were irrigating 4.9 million ha (12 million acres), raising 40% of America's cattle and accounting for a large percentage of agricultural exports. The supply of water from this aquifer is predicted to begin playing out sometime around 2020, slowly shutting down irrigation from south to north. Concern exists that as high yielding irrigation plays out, marginal land taken out of production will be returned to the plow, with similar results as seen in Sub-Saharan Africa with the loss of fallow and expansion onto marginal areas: soil degradation and the potential for a second "dust bowl" (Reisner, 1986). Water supplies are even tighter in California (Brown, 2003b).

Over-pumping for irrigation is a way of satisfying the growing demand for food today that almost guarantees a future drop in food production when the aquifer is depleted. For a few countries, the day of reckoning with aquifer depletion is already here. For many others it is drawing near. Brown (2003a) believes that

"many countries are in essence creating a "food bubble economy"—one in which food production is artificially inflated by the unsustainable use of water. When a stock bubble bursts, the stocks eventually regain their value. But when a food bubble bursts, production may not regain earlier levels. With aquifer depletion, either the rate of pumping is reduced to the level of recharge, if it is a replenishable aquifer, or pumping ceases

entirely, if it is a fossil aquifer. This consequence of excessive reliance on underground water was not obvious when farmers began pumping on a large scale a few decades ago. The great advantage of pumping groundwater is that farmers can apply the water to crops precisely when it is needed, whereas surface water is released for everyone at once, whether or not that is the best time for individual farmers. Groundwater, in contrast, is also available throughout the year, including during the dry season, enabling farmers to double crop their land”.

Overcoming Institutional and Policy Constraints to Irrigation, Mali

Social, institutional and economic factors appear more important than technical limitations to irrigation.

Irrigated rice production has increased steadily in Mali since the trade liberalization of cereal markets and the rehabilitation of abandoned rice perimeters. The *Office du Niger* reports that between 1983 and 1994, the number of farmers participating in the irrigation scheme tripled, average paddy yields tripled, and per capita paddy production nearly doubled (FEWS, 1997).

There is thus a major need to have a bottom-up participatory approach with small-scale farmers in developing irrigation schemes. IFAD (2001) found a near-total lack of meaningful farmer participation in perimeter planning, crop and technology choice, organization of water and pump use and settling of land tenure disputes. An IFAD-sponsored evaluation of experience with small-scale irrigation found that participation in small-scale irrigation projects has generally been little more than rhetoric.

As discussed above and detailed in Chapter 7, large scale-irrigation makes little or no sense if it is at the expense of traditional production systems and small-scale farmers. Appropriate allocation of water should allow both production systems to

co-exist to some degree. However, controlled flooding appears to take a back seat to other priorities such as producing electricity. The failure to factor in the mitigation of traditional floodplain ecosystems should not be tolerated by the international community, who usually funds and constructs these systems. The failure to address such issues is, in the authors' opinions, a gross violation of human rights.

As available water resources come under severe stress in much of Sub-Saharan Africa, strategies must be found to optimize water use, including improved efficiency, reuse of drainage and wastewater, and coordinated use of surface and groundwater (Lake & Souare, 1997). Analysis of soils, surface and ground water, along with a monitoring program of quality and quantity, is advisable for such schemes, especially for large schemes, which may compete with the public for potable water. For irrigation to be successful in the long-term, this implies careful pre- and post-planning, and a thorough modeling of total water availability and its partitioning to meet irrigation, potable, ecological and industrial needs. With many rivers being international, this may be required at an international regional level (see: Chapter 13, Section 13.11, AFRICA'S POTENTIAL WATER WARS).

Grain for Water

"Our individual daily water requirements for drinking average 4 liters per day, while the water required to produce our food each day totals at least 2,000 liters—500 times as much. In affluent societies, where grain is consumed in the form of livestock products, water consumed as food can easily reach 4,000 liters daily" (Brown, 2003a). "Because it takes 1,000 tons of water (1,000 cubic meters) to produce 1 ton of grain, importing grain is the most efficient way to import water. Countries are now satisfying their growing demand for water by tapping international grain markets. As water shortages intensify, so too will the

competition for grain in these markets. In a sense, to trade in grain futures is to trade in water futures" (Brown, 2003a).

However, if the global grain deficit continues and/or grain is converted to ethanol or bio-diesel in favor of food, this may not be possible (Section 5.3.1, Global Food Production).

Irrigation Losing Out to Cities and Industrialization

Irrigation will also have to compete with cities and industries for available water. In the competition for limited supplies of water among agriculture, cities and industry, the economics of water use does not favor farmers, simply because it takes so much water to produce food. Worldwide, 70% of all the water diverted from rivers or pumped from underground is used for irrigation, 20% is used by industry and 10% for residential purposes (Brown, 2003a).

Water tends to generate 50 to 100 times more economic value used in industries than it does in agriculture. Therefore, as water becomes scarce from an economic sense, it usually makes sense to move that water from irrigated agriculture over to cities (VOA, 2003). While it takes 1,000 tons of water to grow a ton of wheat, it takes only 14 tons of water to make a ton of steel (Brown, 2003a).

In the long-term, can water for irrigation compete with urban demands? Brown (2003a) believes that water consuming waste removal, "sewage" may not be sustainable in the long-term, both in its wastage of water and in its adverse impacts on the aquatic environment (see Chapter 8). This would require new technologies to be developed for sewage treatment and disposal, freeing up more water for irrigation.

However, it is not that simple since 70 - 90% of people living in many developing countries are in agriculture. The question also arises of how to meet the needs of 8 billion people on the planet while at the same time protecting the aquatic ecosystems that we all depend upon, that all life depends upon. Therefore, this requires a very fundamental change in how we use, manage and value water. In 1950, there were 5,000 large dams in the world and today we have 45,000, which means that we are controlling rivers and interrupting natural cycles in a major way. We have done this in a very short period, so ecologically we do not know if it is sustainable (VOA, 2003) (see Chapter 7).

Water Conservation Measures

“Historically, farm productivity was measured in yield per hectare, since land was the constraining resource. But as the twenty-first century begins, policymakers are beginning to look at water as the limiting factor for food production. The common measure that is emerging to measure water productivity is kilograms of grain produced per ton of water.

Although there are many ways of raising irrigation water productivity, a few stand out. For those using surface water irrigation, reducing seepage from the canals used to carry water from large reservoirs to farms cuts water use. It is not unusual, particularly where distances are long, for water seepage losses to reach 20–30%. This water can be saved if canals are lined with plastic sheeting or concrete—a more costly but more long-term solution.

A second approach is to use a more efficient technology, such as overhead sprinkler systems. Commonly used with center-pivot irrigation systems, their weakness is that some water is lost to evaporation even before it hits the ground, especially in hot, arid settings. Low-pressure sprinklers, which release water at a lower level, close to the soil surface, lose less water through evaporation and drift. These are now widely used in the Texas panhandle of the United States, where aquifer depletion is encouraging farmers to use water much more efficiently” (Brown, 2003a).

The gold standard for efficiency is drip irrigation, a method that supplies water directly to the root zone of plants (Table 5.30). “Drip irrigation”, which is only used on 1% of irrigated land worldwide, increases water use efficiency by 95% compared to conventional methods. It is not practical to irrigate wheat or rice with drip irrigation, but you can irrigate cotton and sugarcane and most fruit and vegetable crops and orchard crops. With the grain crops, there have been good increases in efficiency with the use of sprinkler irrigation technologies. Even where gravity systems are in use, better (water) management techniques can improve efficiency (e.g., leveling of the fields) (VOA, 2003).

“In addition to cutting water use by up to half, drip irrigation also raises yields because it offers a constant, carefully controlled supply of water. Israel, where water shortages are acute, is the world leader in developing drip technology. It is also now widely used in other countries, including Jordan and Tunisia. In recent years, the tiniest small-scale drip-irrigation systems—the size of a bucket—have been developed to irrigate a small vegetable garden with roughly 100 plants (25 square meters)” (Brown, 2003a).

Table 5.30: Water productivity gains when shifting from conventional surface irrigation to drip irrigation

Crop	Changes In Yield (1)	Changes In Water Use (Percent)	Water Productivity Gain (2)
Bananas	52	-45	173
Cabbage	2	-60	150
Cotton	27	-53	169
Cotton	25	-60	212
Grapes	23	-48	134
Potato	46	0	46
Sugarcane	6	-60	163
Sugarcane	20	-30	70
Sugarcane	29	-47	143
Sugarcane	33	-65	280
Sweet potato	39	-60	243
Tomato	5	-27	44
Tomato	50	-39	145

Although dropping from US\$ 1,200–2,500/ha to US\$ 425–625/ha (Brown, 2003a), the cost of drip irrigation is still a major factor for small-scale farmers in Sub-Saharan Africa. Other actions include the following (Brown, 2003a):

- Another technique for raising water use efficiency in both flood- and furrow-irrigated fields is laser leveling of the land, a precise leveling that can reduce water use by 20% and increase crop yields by up to 30%, boosting water efficiency by half;
- Shift to more water-efficient grains, such as from rice to wheat (limited by climate over much of Sub-Saharan Africa);
- The economic efficiency of water use can also be raised by shifting to higher-value crops, a move that is often market-driven;
- Institutional shifts, specifically moving the responsibility for managing irrigation systems from government agencies to local water users' associations, can facilitate the more efficient use of water. Farmers in many countries are organizing locally so they can assume this responsibility. Since local people have an economic stake in good water management, they typically do a better job than a distant government agency;
- More and more countries are turning to local rain water harvesting to ensure adequate supply more than outweigh this additional expenditure, as opposed to environmentally and socially adverse large-scale dam schemes (e.g., mini-barrages at a local level);
- Another technique to retain rainfall is the construction of ridge terraces on hillsides to trap rainfall near where it falls, letting it soak into the soil rather than run off; and
- The water storage capacity of aquifers can also be exploited. In some ways, they are preferable to dams because water underground does not evaporate. Percolation from locally constructed water storage facilities

often helps recharge aquifers. Similarly, land that is covered with vegetation retains rainfall, reducing runoff and enabling water to percolate downward and recharge aquifers. Without vegetative cover, rainfall runs off immediately, simultaneously causing flooding and reducing aquifer recharge, thus contributing to water shortages. In effect, floods and water shortages are often opposite sides of the same coin. Reforestation, particularly in the upper reaches of a watershed, not only helps recharge aquifers but also conserves soil that if washed away might end up behind dams downstream, reducing the storage capacity of reservoirs.

5.12.1.4 Managing genetic resources of soil biota for enhanced productivity and plant health

Soil biota are responsible for decomposition; nutrient acquisition, storage and cycling; soil organic matter synthesis and mineralization; soil structural modification; regulation of atmospheric composition; and the biological control of soil borne pests and diseases. There is a major need for further research in the biological processes of soil, which lags behind research on the physical and chemical management of the soils (CIAT, 2002).

5.12.1.5 Selection of crops appropriate to the soils and ecology

René Dumont (1966) gives the southern Ivory Coast as an example, where rich forests were cleared yielding four harvests of coffee, but exhausting the soils. On the other hand, over 75 tons of palm oil could have been harvested from the same area in 25 years without leaving the land impoverished if well manured and maintained. He saw coffee plantations fail in the Central African Republic (CAR) from being located in the inappropriate climatic dry forest zone.

Many crops around the world are grown in climates that are not appropriate to those crops. Thus, a lot of water is required to grow cotton or rice in very dry climates where those crops may not be appropriate to production there. Therefore, better matching of the growth of crops with the climate in those regions could help make more efficient use of water. The use of scarce water on marginal lands may just not make sense anymore. There are parts of China, India, Pakistan and the United States – most of the major irrigators - where this may be the case (VOA, 2003).

This is where vocational training of farmers and agriculture extension are needed to advise farmers on their best crop options and on appropriate soil maintenance technologies (Dumont, 1966).

5.12.1.6 Adoption of soil conservation practices by small-scale farmers

Small-scale farmers will determine if they buy into soil conservation practices. Attempts to impose such practices and other technologies on them have tended to fail. The following points must be considered when soil conservation programs are planned (Nana-Sinkam, 1995):

- Farmers and other land users need to be involved right from the start of schemes;
- Adoption of conservation methods will depend on benefits in the form of increased or more assured yields, higher incomes or the reduced need of an input such as labor; and
- “Land tenure” is critical, as farmers will see little point in carrying out conservation work on land to which they have no assured long-term use, which depending on the system could be common property or by individual title.

Farmers and grazers are the most important part of this trio because they are in direct contact with the land and are the very people who must actually use and conserve the croplands, forests and rangelands. Any land use strategy must be farmer, grazer and forester oriented, that is from the “bottom-up”, not a “top-down” approach (GEF, 1998).

Soil Conservation Kitui, Kenya

Farmers in the Kitui area of Kenya are now terracing their fields at their own expense. The terraces very effectively prevent soil erosion, but it has been shown that in this area they also lead to yield increases in the order of 40-90%, and it is probably for this reason that they are being installed (Nana-Sinkam, 1995).

Soil Conservation Machakos Highlands, Kenya

Initial attempts at soil conservation through destocking livestock in 1938 and mechanical terracing in 1946 met with resistance. People were against forced labor two days/week under the supervision of headmen or chiefs on their land, since traditional law gave the person cultivating ownership rights to the land. The type of terracing easily collapsed in storms. This was gradually replaced by farmer-led innovations in terrace construction that has resulted in a four-fold increase in agricultural production per head in the over-populated Machakos District (Tiffen, Mortimore & Gichuki, 1994; Tiffen & Mortimore, 1994 both *In:* Moorehead & Wolmer, 2001 *In:* Devereux & Maxwell, 2001a; Carswell, 2003 *In:* Beinart & McGregor, 2003). René Dumont (1966) attributes this success, which took place during the Mau Mau uprisings, to Kamba leadership learning to help itself and thus adopting these innovative practices, transforming what had been “stark red beacons of eroded hills” into “wooded, terraced slopes, dotted with trim, white-washed homes”. Carswell (2003 *In:* Beinart & McGregor, 2003)

places improved access to markets in the late 1950s as a major reason for adopting soil conservation practices that would increase yields and thus income. She explains how the introduction of the cash crop of coffee in Nyeri, Kenya around 1950 also made terracing acceptable to the local people. Nana-Sinkam (1995) places title deeding of land as a major incentive for adopting terracing in Machakos.

In other cases, traditional terracing existed and thus European ideas were readily adapted such as in southwestern Uganda, (see Section, 5.6.1.8 Impacts of colonialism on traditional agriculture in Uganda).

5.12.1.7 Adoption of appropriate mechanization technologies

Many people may be surprised, but over much of Africa in 2003, agriculture is still undertaken by hand with a hoe. The next step up in intermediate technology is the animal drawn plow followed by full mechanization with the tractor.

“Draught animals (mainly work oxen) are a significant or predominant source of power in countries where incomes are higher and is associated with an increase in intensity of cultivation on both rainfed and irrigated land, and an increase in the area under irrigation (but no expansion of rainfed land). It appears that use of animals does not displace labor. At the other extreme, tractor-based cultivation systems are generally characterized by high GDP per capita (more than \$3000 per head) and where less than half of the economically active population works in agriculture; there are relatively larger areas cultivated per person (1 to 2 ha of harvested area). In Sub-Saharan Africa at present hand power is dominant particularly in Central Africa and Western Africa where it accounts for 85% and 70% of harvested area respectively. In Western and Eastern Africa there is significant use of draught animals despite humans remaining the major power source; there is increasing use of tractors in Southern Africa” (NEPAD, 2002).

René Dumont (1966) refers to the case study of the failed colonial ground-nut scheme in the then Tanganyika [see Section, 5.6.1.9, Failure of colonial groundnut scheme in Tanganyika (Tanzania)] and a similar failure of a groundnut scheme in the Casamance of Senegal. The scraping and hauling involved in felling trees and too deep ploughing brought barren soil to the surface requiring vast quantities of fertilizer, resulted in accelerated soil erosion and, with the irregular rains, either hardened the ground and/or rotted the seeds. He gives other examples of mechanized agriculture destroying the fragile top soils on tobacco plantations in the northern Republic of Congo (Brazzaville), and on rice plantations in the Niger Valley (Guinea-Conakry, Mali and Niger), on the Logone River of Chad/Cameroon and in Madagascar. He was a believer in animal drawn ploughs, which have minimal operation and maintenance problems and in many cases are more cost-effective. Likewise, Rosenblum and Williamson (1987) explain how soil previously turned over but protected by traditional short-bladed hoes was carried away by the wind when tractors introduced by the West tore up the fragile surface. The pros and cons of animal traction versus tractors would need to be investigated on a case by case basis.

The principal author's experience in the SAED project, Senegal would tend to confirm René Dumont's concerns. In the 1980s, graveyards of tractors were seen scattered about the SAED irrigation scheme, a few operating, while skeletons provided spare parts. Part of this is also due to what René Dumont (1966) calls the unhealthy economic mentality of Africa resulting from foreign aid, 'This money didn't cost us anything, who cares if it doesn't bring in much', and when the vehicle or tractor breaks down from lack of maintenance, the donors will buy us more. There is also often a maintenance problem associated with tractors of many makes, each supplied from the respective donor's country without adequate spare part supplies. It also demonstrates the inefficiency and continual failure of state parastatals throughout Sub-Saharan Africa.

With proper vocational training in operation and maintenance and careful evaluation of how to best till the soil, tractors may eventually become useful as traditional agriculture becomes operational on a commercial scale, while draught animals and plows fulfill the intermediate stage in agriculture, which can result in a significant increase in production if other constraints are taken into account.

Decreased rural labor from increasing urban migration of the young and HIV/AIDs (e.g., by 2020 projected loss of agricultural labor of 20% in East and Southern Africa) may make the adoption of draught animals a prerequisite to maintaining and/or increasing agricultural production (NEPAD, 2002).

5.12.1.8 Infrastructure technology as an incentive to increased agricultural production

The Commission for Africa (2005) estimates that 50% of Africa's produce is lost due to poor storage facilities and transport to facilitate access to markets. An investment in infrastructure of US\$ 30-50 million over a ten-year period could save US\$ 480 million each year for maize alone.

Highways, railroads, trucking operations, modern grain storage, access to affordable electricity, etc. must be considered key to helping farmers reduce costs, maximize profits and minimize losses of their produce between harvest and sale to consumers. For example although Africa has 13% of the world's population it consumes only 3% of global commercial energy and by 1991 fewer than 22% of African households were connected to (electrical) networks (NEPAD, 2002). Likewise, Africa lags behind the rest of the world in road infrastructure (Table 5.31).

Table 5.31: Road infrastructure in Africa compared to other developing regions

Region	Total Roads 1,000' km	Paved Roads	Unpaved Roads	% Paved
Africa	2,750	572	2,178	27
North Africa	274	177	97	65
Sub-Saharan Africa	1,817	284	1,533	16
Developing Countries	14,256	4,806	9,450	34
Latin America and the Caribbean	3,235	534	2,701	17
East Asia	2,118	703	1,414	33
South Asia	3,858	1,700	2,158	44

Source: NEPAD (2002) with permission, NEPAD.

“Only 21% of this region’s population live within 100 km of the coast or of a navigable river, against 89% in high-income countries. The proportion of the population that is landlocked is seven times higher than in rich countries. Landlocked countries in Africa have average freight costs almost three times higher than in high-income countries” (FAO, 2002a).

“A fifth (20%) of Africa’s population is landlocked - less than a third (33%) of Africans live within 100 km of the sea compared to over 40% for other developing regions...recent studies in Burkina Faso, Uganda and Zambia have shown that walking is the principal means of transport for 87% of rural households...Local road densities in a sample of representative countries in Sub-Saharan Africa show a mean density of 0.86 km/1,000 head of population, while the equivalent density in Tunisia is 2.6 km/1,000 persons, and in South Asia is some 1.8 km/1,000 persons; for middle-income countries, the density is 8.5 km/1,000 persons. Africa has the lowest density of paved roads of any of the world’s regions, which hinders access to markets” (NEPAD, 2002).

About 33% of Africa (15 of 47 countries) is landlocked, and the only river navigable from the ocean to long distances inland is the Nile (Diamond, 2005b).

“The region’s largely landlocked geography, low population density, large rural population and low share of people living near the coast or an ocean-navigable river, make infrastructure provision costly, particularly transport, communications and electricity...Africa’s transport costs – local, national, or international – are today around twice as high as those for a typical Asian country” (Commission for Africa, 2005).

Maintenance of paved roads is among the most expensive part of a country’s budget. More than 80% of unpaved roads in Sub-Saharan Africa are only in fair condition, and 85% of rural feeder roads are in poor condition, with accessibility limited in most cases to the dry season. About 33% of the roads built in Sub-Saharan Africa in the past 20 years have eroded from lack of maintenance (World Bank, 2000). Paved roads, which a country cannot maintain, are more treacherous and slow than well maintained gravel/dirt roads. In much of Sub-Saharan Africa, unpaved roads graded at least at the end of each rainy season may be the most cost-effective means of developing a viable transport network, until the wealth of the continent increases and the means exists to maintain paved highways. In planning a road network to facilitate the marketing of agricultural produce, the pros and cons of paved versus unpaved highways must be carefully considered based upon the physical environment where the road is to be built (e.g., high versus low rainfall areas, geological structure/erodability), the type and amount of traffic, and the ability of the country to afford the construction and recurrent maintenance costs. South Africa’s creation of a network of toll roads along major routes as a means of maintaining paved highways should be strongly considered by the rest of the continent.

Africa’s rail freight is under 2% of the world total, the marine freight capacity is 11% (much being foreign owned but registered for convenience in Africa) and air freight is less than 1% of the global total (NEPAD, 2002).

In a number of countries, the share of transport cost in value of trade is staggering: for example, transport and insurance payments as a percentage of the value of exports are: Malawi (55.5%), Chad (51.8%), Rwanda (48.4%), Mali (35.6%), Uganda (35.5%) and the CAR (32.8%). These costs are damaging for agricultural trade where primary products are often of low value and great bulk (NEPAD, 2002). This may also be a good argument for transformation/beneficiation in Africa prior to export as a means of reducing these costs! Mellor (1990a *In: Eicher & Staatz, 1990*) believes that foreign assistance in training and infrastructure are critical to the development of African agriculture, along with stabilization of export earnings.

NEPAD's (2002) plans for improved infrastructure include rail transport, improved road networks, telecommunications, power, ports, shipping and transit facilities, crop storage facilities, livestock watering points, fishery landings, marketing and processing facilities, harnessing modern information and communications technology, and encouraging private sector participation in infrastructure financing and operation.

5.12.2 Lost Grains of Africa

Little or no interest has been shown in developing GM food crops for poor developing world farmers (Diamond, 2005a). A National Academy of Sciences (NAS) (1996) publication on the “Lost Crops of Africa” estimates that there are 100 indigenous grasses/grains known to certain Africans but “lost” in the sense that they are being neglected in the fight against hunger. These under-exploited food plants open a new window on ways to help Africa overcome the looming crisis. These plants have much to offer, and not just to Africa. Indeed, they represent an exceptional cluster of cereal biodiversity with particular promise for

solving some of the greatest food-production problems that will arise in the 21st century. Africa's native grains tend to tolerate extremes (Vietmeyer, 1996):

- Pearl Millet (*Pennisetum glaucum*) - a 4,000 year old grain that tolerates heat and drought better than other major cereals;
- Fonio (*Digitaria exilis*) - a West African grain that is gaining popularity, but typically grown on small farms for home consumption. The plant does well in poor, sandy and lateritic soils;
- African Rice (*Oryza glaberrima*) - the native variety of this grain matures very quickly for multiple plantings;
- Sorghum (*Sorghum bicolor*) – a grain that has been spreading from Africa to become a staple of more than 500 million people in 30 nations. As such, it is still relatively underdeveloped. Sorghum thrives on marginal sites where other grains fail; and
- Tef (*Eragrostis tef*) – adapted to cold, a staple of Ethiopia is ground into flour and used to make flat, fermented bread called *injera* that sustains millions.

For thousands of years, these traditional cereals have yielded grain even where land preparation was minimal and management poor. They combine well with other crops in mixed stands. Some types mature rapidly. They tend to be nutritious. The grains of Africa retain much of the hardy, tolerant self-reliance of their wild savanna ancestors. For the future, such resilient crops will be vital for extending cereal production onto the ever-more marginal lands that will have to be pressed into service to feed the growing population. Moreover, if global warming occurs, they could even become vital for keeping today's best arable lands in production. Research is needed into improving characteristics and yields from these indigenous grains.

5.12.3 Decentralization

“In the Sahel there is general recognition in the region that central governments are poorly placed to make many decisions appropriate for local levels. Particularly in areas of agriculture and natural resource management (NRM), local populations are being asked to take leadership in deciding appropriate land uses and ownership/usufruct of resources. Decentralization laws (i.e., devolving decision-making authority over local matters, particularly land use and natural resource allocation) such as those in Senegal, Niger, Mali, Burkina Faso, and The Gambia are attempts to facilitate the needed restructuring and empowering of local populations. The reality of decentralization so far is that local decision-makers have very little discretion in decision-making, and few skills for effective implementation and monitoring of decisions taken. The institutions which have been set up to govern natural resources at the local level rarely have budgetary discretion, perceived local legitimacy, and a mandate for more than awareness-building. This is particularly the case where local governmental units have been newly created or empowered by decentralization laws. As a result, the current policy of decentralization across West Africa has become largely a matter of deconcentration (i.e., strengthening the national government at the local level) of state power” (Moore, *et al.*, 2000).

The real issue is land and resource tenure and the right to control harvest and economically benefit as a means of achieving full devolution (see Section 5.7.1, Property Rights and Land Tenure, Constraints to Soil Fertility and Agricultural Production and Chapter 9, COMMUNITY BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS - THE WAY FORWARD? for further discussion).

Gestion Des Terroirs (GT), Decentralization West Africa

“To alleviate effects of periodic drought and promote development, different types of strategies have been implemented to assist agro-pastoral groups. Most recent among these have been participatory approaches that coincide with the growing trends of

democratization and decentralization. Previous interventions, although systematic, have largely failed to increase agricultural or livestock production and have even resulted in higher rates of depletion of natural resources. The reason for such poor results is generally perceived as stemming from the weak involvement of the local population in the conception, design, implementation and evaluation of these interventions that were consequently seen as being imposed on the local communities” (Moore, *et al.*, 2000).

GT is a multi-sector and global strategy aiming to establish new socio-economic and ecological equilibrium in order to achieve food self-sufficiency and to preserve/regenerate the productive potential of natural resources.

“The GT approach centers on organizing local (village(s) or *terroir/territory*) management committees and, from this base, begins the consensus-building process toward village-level management of natural resources...Despite the promise of these forms of local management for the future of Natural Resources Management (NRM), they still need considerable support in the form of literacy and budgetary training and although diversity of committee membership is urged, the tendency is for local elites to dominate and for women and pastoralists to be excluded (Bohrer & Hobbs, 1996 *In:* Moore, *et al.*, 2000). The GT’s greatest strength is also its greatest shortcoming. Because it is village-based, it is close to the people and can potentially be very participatory. However, because it is village-based, the committees are far removed structurally from the lowest governmental administrative level (typically composed of tens of villages) that has the decentralized mandate and potential resources appropriate to effectively manage natural resources” (Moore, *et al.*, 2000) (see Chapter 6, Section 6.1.5.2, Decentralization and creation of pastoral associations in West Africa and Chapter 9, Section 9.8.9, Gestion Des Terroirs, West Africa for further discussion).

Decentralization of Land Tenure by Government of Mauritania

“In Mauritania, a land tenure law adopted in 1983 had the stated objective of providing security to farmers by facilitating access to private land ownership. The law required the transfer of traditional property and use rights to the state, as a first step of a lengthy and

complicated process. It also required local communities to organize themselves as cooperatives in order to maintain their communal rights to the land. The law was used in some irrigated perimeters in the Senegal River Valley but practically never by peasant communities and traditional landowners in other areas. In reality, it presented a serious obstacle to irrigation development and community involvement in land improvement. It also tended to make land tenure arrangements exploitative and insecure" (IFAD, 2001).

Often, political elites expropriated land from peasants (see Chapter 7, Case study of Dams on the Senegal River).

"Under the Maghama Improved Flood Recession Farming Project, the possibility of substantially increasing flood recession farm land (from less than 4,000 ha to more than 9,000 ha) in an area dominated by traditional land-use arrangements presented IFAD with an opportunity for proposing a change of policy to the Government, involving devolution of local land tenure arrangements to the village populations concerned. A decree was promulgated in 2000 providing for beneficiary involvement in the resolution of land tenure issues. An overall framework agreement and individual arrangements guarantee secure access for at least 15 years to land upon which improvements are made. Community organizations play a central role in establishing and enforcing land tenure arrangements. Because inter-village cooperation is crucial, a cooperative grouping of all village organizations in the project zone has been created to manage the flood recession scheme" (IFAD, 2001).

5.12.4 Education, Research and Extension, Corner Stones for Development of a Land Ethic

Africa's scientific and institutional gaps should come as no surprise because of colonial under-investment in training (Eicher, 1990 *In:* Eicher & Staatz, 1990).

While donors and governments have invested heavily in African research and extension systems, these institutions have been ineffective in developing and extending technologies that respond to farmers' needs. National agricultural research and extension agencies have steadily deteriorated over time (see Chapter 12 Section 12.4.5, Decline in Research and Extension as a Result of Structural Adjustment), lacking both government and donor support, along with little incentive for qualified local researchers to develop their skills. However, in the long run preferably food security or

"food self-sufficiency in Africa will to a large extent depend upon agricultural research and development and the effective transfer of results to the farmer through extension services" (Alemayehu, 2000).

Since the 1970s and early 1980s, because of poor results from integrated rural development projects and farming systems approaches, donor interest in agricultural research and extension in Africa has declined (IFAD, 2001). The question that must be asked is how to overcome these hurdles. This will require better training of farmers (e.g., more farmers with secondary and tertiary education), and better training and motivation of extension agents who work with farmers, along with addressing land/resource tenure.

International research centers come under two major umbrella organizations: 1) the Washington based Consultative Group for International Agricultural Research (CGIAR) in Anglophone countries with 16 centers – 13 in developing countries, and 2) Center of International Cooperation In Agricultural Research & Development/*Centre de Cooperation Internationale En Recherche Agronomique et Developpement* (CIRAD) in the French speaking countries. A major criticism is that they have tended to go for Green Revolution technologies in favor of pulses (e.g., peas) and coarser grains. Successes from these research institutions include (Madeley, 2002) the:

- International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) conducting research to improve yields of often neglected “orphan” crops such as pigeon pea, groundnuts and pearl millet; and the
- International Institute of Tropical Agriculture (IITA), International Centre For Tropical Agriculture/*Centro International de Agricultura Tropical* (CIAT) and the International Centre for Agricultural Research in Dry Areas (ICARDA) are developing technologies for small-scale farmers that do not require chemical inputs.

Sub-regional organizations for Strengthening Agricultural Research (SROs); the Association for Strengthening Agricultural Research in Eastern and Central Africa (ASARECA), *Le Conseil Ouest et Centre Africaine pour la Recherché et le Développement Agricoles*/West and Central African Council for Agricultural Research and Development (CORAF/WECARD) and the Southern Africa Centre for Cooperation in Agricultural Research and Training (SACCAR) jointly established the regional Forum for Agricultural Research in Africa (FARA). The establishment of FARA completed the chain linking African agricultural scientists to the Global Forum for Agricultural Research (GFAR) (NEPAD, 2002).

There is a need to focus more on Low-External Input (LEI) agricultural research to meet the needs of small-scale farmers (Madeley, 2002) to overcome the serious problems of mining soils in many parts of Africa. These steps include 1) widespread soil testing, 2) closer cooperation and coordination between farmers and researchers to exchange information and disseminate technologies that take into account immediate farmer survival needs along with longer-term soil fertility and agricultural sustainability requirements, 3) encouragement of extension services and NGOs to pay attention to soil-related issues, 4) promotion of more

productive use of organic nutrients and 5) promotion of vegetative-cover methods to conserve soil moisture and nutrients (Gruhn, *et al.*, 2000).

Agronomic research has contributed to impressive increases in maize yields in parts of Mali, Senegal, and Burkina Faso in the last 15 years by breeding short-cycle varieties that are more resistant to drought. When Malian farmers have applied fertilizer to the new varieties, they have enjoyed a near tripling in maize yields, and they have responded by planting ten times more land to maize.

Improved millet cultivars are being adopted in the Groundnut Basin of Senegal, and improved cotton cultivars, used in conjunction with chemical fertilizers and pesticides, are contributing to yield gains in Burkina and Mali. In the latter case, animal traction has helped farmers to increase yields further by enabling them to cultivate the heavier, often richer, soils and by relieving labor bottlenecks at key points during the growing season. Small dikes constructed in the depressions (*polders*) between dunes alongside Lake Chad and in seasonal riverbeds (*wadis*) have provided enough moisture to double wheat yields. These success stories are all similar in that each depends on a minimal level of soil moisture (FEWS, 1997).

Farmers need to know how to combine organic fertilizers with chemical fertilizers, apply improved pest and weed management techniques, and adopt high yielding crop varieties (Kumwenda *et al.*, 1996 *In:* Gruhn, *et al.*, 2000). Insufficient attention to effective crop nutrition and soil fertility management studies has also made it difficult to improve yields in Africa, even when improved germ plasm has been made available. More research, expanded extension, and greater integration of knowledge could provide farmers with a stronger incentive to improve yields, maintain soil fertility and sustain agriculture.

CIAT (2002) recommends a combination of short-term, degree related and on-the-job training activities, including at the university level.

Though Africa will still need to formally train technicians in environment related disciplines, the key element for success is going to be working with farmers and/or other natural resource users (e.g., fishermen, traditional hunters, herders, charcoal makers, pit sawyers, etc. to put into place sustainable natural resource practices. Since the farmer manages the land, he/she will ask specific, environmental questions and the expert or technician will try to answer them. Knowledge that has not incorporated local information and wisdom cannot possibly provide appropriate answers for such questions (Nana-Sinkam, 1995; CIAT, 2002). Thus, the blending/integration of modern essentially “Western intensive resource management systems” with “traditional/indigenous knowledge of extensive resource management systems” along with traditional values and cultural beliefs will be necessary if research and extension is to be successful in Sub-Saharan Africa. Too often, the importance of this process is ignored! NEPAD (2002) has indicated that

“to avert food insecurity and reduce poverty, African leaders have set a target to increase agricultural output by 6% a year for the next 20 years. At present, many countries barely achieve 1% annual growth in output and some are regressing. Without technological upgrading and adoption, even large-scale investment would soon perform sub-optimally and fail to gain for Africa the success it needs.

Achieving a 3% annual growth rate will require: (a) acceleration of adoption for the most promising available technologies so as to support immediate improvement of African production by way of linking, more efficiently, research and extension systems to producers; (b) technology delivery systems that quickly bring innovations to farmers and agribusinesses so making increased adoption possible, notably through an appropriate use of new information and communication technologies; (c) renewing the

ability of agricultural research systems to efficiently and effectively generate and adapt to Africa new knowledge and technologies, including biotechnology, needed to increase output and productivity while conserving the environment; and (d) mechanisms that reduce the costs and risks of adopting new technologies. To do this requires several lines of action, of which the following may be highlighted:

- Increasing investment in research and technology development;
- Increasing the share of private sector funding of agricultural research;
- Institutional and financial reforms aimed at making national agricultural research systems more sustainable.

The proposed NEPAD research program would be comprised of four sub themes which would collectively contribute to testing the central hypothesis: 'that conservation and efficiency of use of soil and other natural resources will be optimized under conditions of market and/or policy and institution driven productivity.' The four research themes are:

- Integrated Natural Resource Management;
- Adaptive management of appropriate germ plasm;
- Development of sustainable market chains;
- Policies for sustainable agriculture.

In addition, there is to be a crosscutting initiative:

- Scientific capacity building.

Underlying the inclusion of the chapter on research is the key message that in pursuing immediate responses to its agricultural crisis, Africa cannot afford to be short-sighted: it must keep an eye on factors essential for its continuing long-term competitiveness and productivity".

A major problem for the long-term sustainability of agricultural research is getting off the donor dole and obtaining political support from other stakeholders.

"Both research and extension services in Africa depend heavily on donor funding. Contributions from donors now provide more than

40% of all funds for agricultural research. This is up from 28% in 1986 and exceeds the level of any other region. Given the fragile economies and extensive demands on the public sector in many African countries, donor support for research and extension will continue to be important for some time to come. However, African research and extension managers must start building political support for their programs among farmers, private firms, and other beneficiaries of more productive agricultural systems. They must start diversifying their sources of funds through producer levies, contract research, joint ventures with the private firms, and the like. Finally, they must open the research and extension systems to more providers, strengthening links between universities, non-governmental organizations, private firms, and others nationally and regionally" (NEPAD, 2002).

Cassava Mealy Bugs, Green Mites and Their Control, a Success Story in Research and Extension

"Introduced into Central Africa by Portuguese traders in the 16th century, cassava has established itself in much of West and Central Africa (WCA) as an important staple crop. However, while highly adaptable and robust in many different settings, cassava has been periodically plagued with devastating diseases. The cassava green mite surfaced on imported farm machinery coming into Uganda in 1971, while the cassava mealy bug emerged first in D.R. Congo in 1973, accidentally imported from its native South America. In the absence of their natural predators, both spread rapidly across the continent. The mealy bug, the more voracious of the two, caused crop losses of 80% as it ate its way across the continent at over 300 km per year. By the early 1980s, it had infested the entire African cassava belt, threatening the principal food source of over 200 million Africans" (IFAD, 2001).

"In 1981, after a year of intensive exploration, researchers at the International Centre for Tropical Agriculture (CIAT) and the Commonwealth Agricultural Bureau's International Institute of Biological Control identified a natural predator of the mealy bug in South America, a parasitic wasp. IITA (International Institute For Tropical Agriculture), with strong funding primarily from IFAD (International Fund For Agricultural Development) and other donors, rapidly mounted a mass rearing and distribution program

in collaboration with African National Agricultural Research Systems. First released in 1981, the predator wasp had, by 1988, largely controlled the mealy bug threat throughout Africa. Conservative estimates place the value of production saved at over US\$ 2.2 billion against a program cost of US\$ 15 million, generating a spectacular benefit cost ratio of 149. Spurred on by the success, researchers at IITA and CIAT redoubled their efforts to find biological solution for the lingering, but deadly, cassava green mite. Though work preceded more slowly than with the mealy bug, researchers eventually identified a suitable predator mite, which they released in a dozen sites across the continent beginning in 1993. A ferocious predator, it reduces the cassava green mite to a dried up shell in minutes. Widely credited with preserving the cassava crop in 20 African countries, in 1997, the Washington Post dubbed the predator mite ‘the bug that saved Africa’ ” (Gabre-Madhin & Haggblade, 2001 *In: IFAD, 2001*).

Buy-In to Special Program for Food Security (SPFS)

“SPFS was launched in 1994 by FAO as a means of achieving and sustaining a higher level of household and national food security. By 1992, the SPFS is operational in 68 countries of which 38 are in Africa: it has been formulated or is under formulation in another 16 countries, of which 6 are in Africa. The SPFS is implemented in a stepwise fashion, starting with pilot activities initially at a few locations (Phase I) which are progressively scaled up with the aim of gaining pilot experience in all major agro-ecological zones in a country...self-selected groups of small-scale farmers at a limited number of sites. As experience is gained and good practices are developed they are then replicated over an increasing number of sites. Depending on locally identified needs and opportunities, this first phase generally consists of four complementary components which touch on most aspects of agricultural development, viz.:

- Water and soil management: measures to address moisture limitations and excesses through low-cost irrigation, water harvesting and drainage methods, and through land husbandry systems which improve soil physical, chemical and biological conditions and avoid soil erosion.
- Raising productivity: actions to raise land or labor productivity on a sustainable basis, including improved varieties adapted to local conditions, integrated plant nutrients and pest management systems

(with a minimum dependence on purchased inputs), and improved post-harvest technologies.

- Farm diversification: measures to improve household nutrition and income and to protect against risk, initially focused on short-cycle livestock such as chickens, sheep, goats, rabbits, bees etc., with an emphasis on enabling farmers to prevent diseases and improve animal nutrition: where appropriate, support is also given to artisanal fisheries and aquaculture.
- Participatory study of socio-economic constraints that restrict farm-level profitability and food security, prevent the emergence of greater social equity and impede the implementation of the program on a wider scale.

...The implementation of pilot activities increasingly benefits from the South-South Co-operation initiative (SSC), launched in 1996 to allow recipient developing countries to benefit from the relevant experience of more advanced developing countries. To date countries in Africa have signed 22 of the 26 SSC agreements linking countries in Africa, Asia, and Latin America and the Caribbean" (NEPAD, 2002).

5.12.5 Access to Credit

As discussed throughout this chapter, access to credit can be a major limiting factor in allowing the small-scale farmer to purchase the needed inputs and machinery to increase his/her production.

However, very often it is only a few better-off farmers who are able to take the risk of taking out loans, leaving many of the rural poor in a status quo situation. A UN International Fund for Agricultural Development (IFAD) credit scheme in North Western Province, Zambia to purchase hybrid maize seeds and fertilizers went to only 9,000 out of 160,000 farming families. Most subsistence farmers grew cassava, millet and beans with some maize and were unwilling to take the risk of borrowing. Of those that did borrow, loan recoveries were 46% in 1992, 80% in 1993/4 and only 10% in 1994/5. The low loan recoveries were believed to

be due to a combination of the technologies being unsuitable and/or the farmers lacking the technical skills to take advantage of the technologies (Madeley, 2002).

Thus, credit must be linked to better training of future farmers, research and extension, if it is to be of any real value.

5.12.6 Public/Private Sector Cooperation

“As recently as a decade ago, governments in the Region saw themselves as the prime motors of economic development, today there is increasing recognition by the governments themselves that their direct role in economic activities is a more limited, though at the same time more strategically important in creating conditions for growth. It is a role which is focused particularly on the key area of establishing the policy, legal and institutional framework which enables the private sector to play the leading role in economic development, and in selectively investing in key public goods which will catalyze broad-based economic growth” (NEPAD, 2002)....

“Agricultural production services must not only effectively target smallholder producers, but must ensure that the services provided respond to the constraints they face and opportunities open to them. At the same time, there is need to strengthen the capacity of smallholder producers to define and articulate their requirements in terms of services; organize themselves to better access inputs, produce markets and production services and conduct their own agricultural experimentation; establish a strong voice for themselves in the policy and institution-building process. Supporting the development of producer groups associations is a crucial part of such an approach.

The large-scale formal private sector - particularly agri-business, is in a number of countries of the Region probably the major development partner for smallholder producers. Future progress depends on a broad-based and equitable expansion of these relations - something that will only happen on the basis of mutual interest. The commercial private sector wants to make money. It can do so - and at the same time help poor farmers make more money, if it expands its commercial relations into a realm of self-

organized smallholders who are aware of market options. More and more governments in Africa recognize the crucial role that the private sector must play, and are willing to undertake investments - in policies, institution-building as well in infrastructure - which reduce the transaction costs that the private sector faces in doing business with smallholder producers" (NEPAD, 2002).

However, "the private sector is not increasing its research efforts in Africa as government spending declines. With a share of about 2% of total spending, the private sector plays an exceptionally small role in funding agricultural research in Africa. This is not likely to change soon because the potential profits from conducting research on important crops (e.g. sorghum and millet) in Africa are not sufficiently high to attract the interest of either domestic or international private firms. In industrial countries, private enterprises fund over 50% of agricultural research" (NEPAD, 2002).

Very often, the large-scale formal sector is made up of predominantly of white commercial farmers and/or overseas multi-nationals such as Monsanto. Africans must put aside their racial prejudices and historical past and work towards the future for a prosperous Africa!

5.12.6.1 South Africa, an emerging model in public private partnerships

The South African agricultural black empowerment policy document (AgriBEE, 2004) encourages mentor programs linking white commercial farmers to traditional African farmers as a means of training them in intensive agriculture (see Section 5.7.4.2, Land reform and South Africa). The following was provided by Johan Stander (*pers. comm.*). The Department of Agriculture, Tshwane University of Technology (TUT) is collaborating in a program with the private sector. A coal mining company, XSRATA has picked three black students from TUT and will place them on a commercial "white farm" for one year. They were chosen for their "big picture" thinking skills, which are believed to indicate potential for entrepreneurialism, as farmers are businesspeople. They will each

farm 170 ha of land. Prior to this, they are receiving training in basic farm maintenance skills at a technical training college in electricity, mechanics, plumbing, welding, etc. Their work will be monitored by their “mentor” neighbor commercial “white” farmer. In addition, they will receive continued modular training in farm management, administration, personnel, etc. They will be provided with tractors and shown how to link into support services such as commercial fertilizer and seed companies. If they demonstrate potential, the mining company will help them develop a business plan and obtain a loan to set up one 700-1,000 ha commercial maize farm each. The mentor farmer will continue to provide them with backstopping for the next five years. As a means of economizing, the tractors and combines will be put into a “mechanization unit”, a company that will also have a common office in which the three farmers will be shareholders. Special emphasis will be placed on addressing administration (finances and cash flow) and marketing, which is where most small businesses fail. The mining company will guarantee surety on the loan. Variations on the theme are being implemented with small-scale farmers through the KwaZulu-Natal Agricultural Development Trust that guarantees surety on bank loans to small-scale farmers. In the case of small-scale farmers, the tribal authority determines land distribution, while a community cooperative is established as a legal entity to provide inputs and marketing, while a white commercial mentor farmer works with the small-scale farmers in technology transfer, as well as helping them link to support services (e.g., seed and fertilizer companies who supply both inputs and extension services). The cooperative is self-financing through dues, providing mechanization services (e.g., plowing, seeding, fertilizing, spraying and harvesting) and through the sale of inputs. The commercial farmer normally teams up with one black farmer with the most substantial piece of land who in essence acts as an innovator in his/her area to demonstrate best farming practices to the other small-scale farmers. The

experience has been that the best farmers tend to slowly take over the land of the technically poorer farmers.

Nevertheless, these kinds of public-private-university partnerships need to be part of a big picture plan, which identifies land for redistribution and then has a realistic as opposed to political time line over which people are trained to take over and run such operations. Handing a commercial farm to subsistence farmers risks to see the land degraded and worse - see a major decline in agricultural production. And then, who will feed the cities? Politics must be kept out of the way as much as possible other than for the general concept of land reform, allowing technicians to plan and find the way forward that assures long-term food production and thus security. There is no reason why this model cannot work for much of East and Southern Africa, where white commercial farmers are found. It may even work in Nigeria that has invited a few hundred white commercial farmers from Zimbabwe to establish commercial farms and train Nigerians in such techniques.

5.12.6.2 Private sector and traditional farmer cooperation in the sub-humid zone of Burkina Faso and Mali

“The sub-humid zone of Burkina Faso and Mali covers what has come to be known as the cotton belt of West Africa. Average annual rainfall in this zone is about 800 to 1,000 millimeters. With higher rainfall, the agricultural potential is higher compared with the Sahelo-Sudanian zone. Until recently, the agricultural potential of this area was largely unexploited because of the higher incidence of human and animal diseases, such as malaria, river blindness, and sleeping sickness. Improved public health and modest investment in infrastructure have opened up these areas and facilitated the growth of agricultural production. The predominant crops in this area are cotton, maize, sorghum, millet, cowpea and groundnut. The introduction of new cultivars of cotton and maize has been quite successful and has been combined with rapid introduction of animal traction and improved crop-

management practices, including increased fertilization, plant density, and pest control. This success story has been attributed to a combination of technological and institutional support provided, first, by a French cotton company (*Compagnie Française pour le Développement des Fibres Textiles*)...The essential elements of the strategy included supplying farmers with fertilizer on credit, and providing technical recommendations and purchase of cotton on a timely basis and at a price known before planting" (Lele, van de Walle & Gbetibouo, 1989 *In:* Williams, *et al.*, 2000 *In:* McCarthy, *et al.*, 2000).

As a result, cotton yield increased rapidly from about 200 kg/ha in the mid-1960s to about 1,300 kg/ha in the mid-1980s. These high yield levels were associated with high inorganic fertilizer and pesticide use. Average NPK fertilizer use on cotton in southwestern Burkina Faso in the mid-1980s ranged from 130 to 148 kg/ha, while it was about 190 kg/ha in southern Mali (Savadogo, 1990 ; Girdis, 1993 both *In:* Williams, *et al.*, 2000 *In:* McCarthy, *et al.*, 2000). However, inorganic fertilizer use declined with the elimination of subsidies in the late 1980s. This, together with the worldwide price collapse of cotton in 1986, led to a decline in cotton yields after 1986. However, since then—through greater use of manure and mineral fertilizer—cotton yields have picked up again" (*In:* Williams, *et al.*, 2000 *In:* McCarthy, *et al.*, 2000). Further discussions on cotton and subsidies are presented in Chapter 12, Section 12.2.4.4, Cotton subsidies and protected markets).

5.12.7 Attaining Food Security through More Appropriate Land Use Options

Rather than attempting increased, often prohibitively expensive, uneconomical and environmentally unsustainable increases in agricultural production on much of Africa's "marginal" lands where populations are expanding, there are strong options that wildlife and forestry, as land uses, with their vast array of resources and/or economic activities (e.g., safari hunting, ecotourism, bushmeat, timber,

charcoal, honey, fish, other wild foods, herbal medicines, etc.) may yield greater returns/ha than converting these areas to poorly producing agriculture. This would allow rural communities to both obtain their food as well as to purchase food and develop their area with income and commodities derived from more appropriate use of these natural systems. Chapter 9 provides details and case studies in community management of wildlife, forests and fisheries.

Wildlife as a Land Use Option on Marginal Lands

Over much of Sub-Saharan Africa, especially over vast stretches of the savanna lands that constitute about 70-75% of the land mass, wildlife and/or a wildlife/livestock mix may be a more appropriate use than agriculture.

“Marginal and unsuitable lands, identified by the assessment, should be managed to preserve their quality as they may be too uneconomical or unsustainable to support more than very low intensity traditional systems. These areas may be of benefit to other types of land use such as wetlands needed by breeding fish stocks and wildlife refuges. These marginal lands have been shown to be income producers when managed for wildlife. Kenya and Zimbabwe have been successful in attracting tourists to view wildlife in 'marginal' land set aside as wildlife refuges. Tourism (including hunting) contributes many millions of dollars to the local and national economies of both countries” (Eswaran, *et al.*, 1996).

The game industry in Southern Africa in 1999, primarily from overseas hunting, gross worth was estimated at (see Chapter 9, Section 9.5, SUCCESS OF CBNRM BASED UPON CONSUMPTION AND COMMODITY PRODUCTION):

- South Africa, US\$ 140,062,252 including 1) overseas hunters (20%): trophy fees of \$US 18,395,585 + US\$ 10 million daily rate from 29,275 hunting days, 2) taxidermy (mostly from foreign hunters) (7%): US 10 million 3) local (biltong) hunters (54%): US\$ 75 million, 4) live sales &

capture (18%): US\$ 25 million, and 5) venison market (1.1 %): US\$ 1,666,667 million, creating 63,000 jobs on 9,000 game ranches and 5,000-6,000 additional jobs as safari operators, professional hunters and staff (African Advisory Board, 2000);¹⁰⁵

- Namibia, US\$ 42 million (also includes local hunters, live sales, venison market and taxidermy) (African Advisory Board, 2000), gross US\$ 4.7-5 million from trophy hunting (TRAFFIC, 2001 *In:* Baldus & Cauldwell, 2004);
- Botswana, US\$ 12.5-20 million, trophy hunting only (African Advisory Board, 2000; BWMA, 2001; TRAFFIC, 2001 *In:* Baldus & Cauldwell, 2004);
- Zimbabwe, US\$ 21.1-22.3 million, trophy hunting only (TRAFFIC, 2001 *In:* Baldus & Cauldwell, 2004; Khumalo, 2005)¹⁰⁶ at peak before radical land reform; and
- Zambia, US\$ 12 million, trophy hunting only (African Advisory Board, 2000).

One could likely add a knock-on multiplier of from 5-7 on the overall economy from trophy hunting (e.g., transport, lodging, side eco-tourism trips, souvenirs and restaurants). Lindsey, Roulet and Romanach (2006) provide an overview of the economics and conservation value of trophy hunting in Sub-Saharan Africa, indicating little change since 1999, with the exception of South Africa with regards to gross revenues.

¹⁰⁵ Note: More recent estimates vary widely. Saayman and van der Merwe (2006) estimate that 200,000 South African biltong hunters spend a total of \$US 525,079,000 (R 3,150,474,000)/year including game/trophy fees on hunting; 76% in South Africa, 19% in Namibia, 2% in Botswana and 3% in other countries. Likewise, Lindsey, Roulet and Romanach (2006) estimate that in South Africa by 2005 overseas trophy hunting grossed US\$ 100 million/year, with clients more than doubling from 3,898 (African Advisory Board, 2000) to 8,530 (Lindsey, *et al.*, 2006), in both cases with 55-57% coming from the USA. Cloete, Taljaard & Laubscher (2007) estimate that overseas trophy hunting grossed US\$ 40 million in 2003/04 and US\$ 44 million in 2005/06 and non-consumptive trophy utilization another US\$ 22.2 million in 2004/05. Other estimates are that the overall game industry of South Africa in 2005/2006 is valued at US\$ 670,857,142 (R 4,696 million): 1) Recreational/Biltong hunting US\$ 443 million (R 3,100 million/66%), 2) Taxidermy US\$ 28.6 million (R 200 million/4%) 3) Overseas trophy hunting US\$ 72.9 million (R 510 million/11%), 4) Live animal sales US\$ 13.4 million (R 94 million/2%), 5) Meat production \$US 6 million (R 42 million/1%), and 6) Translocation US\$ 107 million (R 750 million/16%) (NAMC, 2006).

¹⁰⁶ Note estimate of US\$ 70 million for trophy hunting (African Advisory Board, 2000) believed to be too high.

“The World Travel and Tourism Council estimates that travel and tourism accounted for more than 11% of Africa’s GDP in 1999 and projects growth of more than 5% a year (in real terms) over the next 10 years, outstripping global tourism growth of 3%” (World Bank, 2000).

For instance in South Africa the

“tourism sector brings more dollars into the country than gold...In 2003, forex from tourism totaled R 53.9-billion (US\$ 8.3 billion), compared to the R 35.3-billion (US\$ 5.4 billion) from net gold exports...According to the research, tourism contributes about 7% to South Africa's gross domestic product (GDP) and adds more to domestic economic growth than the mining sector, which contributes 5% to GDP...Business tourism (including conference tourism) sustains almost 260,000 jobs in SA, and pays out R6-billion (US\$ 923 million) in salaries and R4-billion (US\$ 667 million) in taxes every year. Despite a global slump, South Africa has continued to defy world tourism trends, and in 2003 achieved a 4.2% increase in overseas arrivals (not including arrivals from Africa) compared to 2002. This in the face of a 1.3% fall-off in global travel attributed to the conflict in Iraq, fears over the Severe Acute Respiratory Syndrome (SARS) virus and a weak global economy. The country's exponential tourism growth has coincided with the its first decade of democracy: arrivals have grown tenfold since 1994, from 640,000 to 6.5-million (annual visitors) in 2003. The Standard Bank research shows that in 2003, more than half of South Africa's tourists came from other African countries - many of them on ‘shopping safaris’ - with visitors from Lesotho, Swaziland and Namibia, whose currencies are pegged to the rand, spending R7.6-billion (US\$ 1.3 billion) in the country” (South Africa Info, 2004).

Forests as a Land Use Option

“Forests including the non-wood forest products are mainly used for subsistence or low-value commerce, such as for fuel wood, (bushmeat, honey and other wild foods, medicine, charcoal). Nevertheless, forests offer many income and employment opportunities including trading in wood fuels, crafts, tourism from wildlife, etc. The uncontrolled harvesting of natural forests has

caused the destruction of biological diversity with minimal economic gains. Lack of value adding processing, and trading in forest products and services, have also reduced the contribution of forestry to economic development in the concerned countries and make forests appear dispensable. Industrial utilization of forest products has shown greatest success in plantations development, with forest-poor countries e.g., South Africa being the prime exporters of forest based products while forest-rich countries export raw logs or low-value wood” (NEPAD, 2002).

There is a need for more transformation/beneficiation of forest products in Africa, to empower rural communities to sustainably manage their forests, to assure that foreign logging companies in cahoots with national and local governments are not mining these resources, and to assure that communities are receiving their rightful share of products being harvested from the forests. Land and resource tenure are major policy issues at the heart of this problem, along with education and training of rural communities in the, value, marketing and management of these resources.

Concerning “*green label*” schemes said to assure sustainable commercial logging mostly by European companies in Sub-Saharan Africa’s tropical lowland hardwood forests (e.g., Liberia, Cameroon, Congo Brazzaville, DRC),

“nongovernmental actors and a few governments devised certification schemes for environmentally sound harvesting of lumber and pulp wood...A major limitation to certifying sustainable forest practices in the tropics is that ‘sustainable tropical forest management’ has not yet been defined in an operational sense. And some conservation organizations consider certification schemes (green label schemes) to be ‘greenwash’ because the standards are so weak and vague that any relation between compliance and true sustainability would be impossible to verify. In short, sustainable forestry remains little more than a pipe dream. Logging practices are governed far more by market forces than by long-term sustainability. Biodiversity losses continue to accelerate” (World Economic Forum, 2004) (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the

Forest People and the *Dobi Dobi*, More Parks and Protected Areas and Section 11.11.7, Case Study Bongo in the Congo (Brazzaville).

5.12.8 Moving Lower Down the Food Chain to Produce More Efficient Protein

“As both the oceanic fish catch and the production of beef on rangelands have leveled off, the world has shifted to grain-based production of animal protein to expand output. And as the demand for animal protein climbs, the mix of protein products consumed is shifting toward those that convert grain into protein most efficiently, the lower-cost products. Health concerns have also prompted some people to shift consumption from beef and pork to poultry and fish” (Brown, 2003a).

It should be noted that with the exception of South Africa and unlike Europe and America, most livestock in Sub-Saharan Africa are grass and not grain fed.

Aquaculture

“The efficiency with which various animals convert grain into protein varies widely. With cattle in feedlots, it takes roughly 7 kg of grain to produce a 1-kg gain in live weight. For pork, the figure is close to 4 km of grain/kg of weight gain, for poultry it is just over 2, and for herbivorous species of farmed fish (such as carp, tilapia, and catfish), it is less than 2. As the market shifts production to the more grain-efficient products, it raises the productivity of both land and water” (Brown, 2003a) (Table 5.32).

“The big winner in the animal protein sweepstakes has been aquaculture, largely because fish are highly efficient at converting feed into protein. Aquacultural output expanded globally from 13 million tons in 1990 to 38 million tons in 2002, growing by more than 10% a year” (Brown, 2003a) (Table 5.32). However, this should not be an excuse for not sustainably managing the world’s natural fisheries or other renewable resources” (Brown, 2003a).

Table 5.32: Annual growth in world animal protein production by source, 1990-2002			
Source	1990 (Million Tons)	2002 (Million Tons)	Annual Growth (Percent)
Aquaculture Output (1)	13	38	10.2
Poultry	41	72	4.8
Eggs	38	58	3.6
Pork	70	94	2.5
Mutton	10	12	1.5
Oceanic Fish Catch (1)	86	91	0.5
Beef	53	58	0.8

(1) Oceanic fish catch & aquaculture output figures for 2001

Improved Management and Marketing of Wild Fisheries as a Source of Protein

“The fishery sector in Africa is characterized by a dualistic structure with an industrial sub-sector, composed by large boats operating on a purely commercial basis targeting high quality/high value fish to serve northern markets and a high degree of vertical integration from fishing through storing and processing up to marketing in northern markets. Most value added is therefore kept by the company itself and very little left within the country, as post-harvest infrastructure, where existing, is limited to storage capacity and very little processing. On the other side is the artisanal sub-sector, composed by African fishermen engaged mainly for subsistence and the local market, using labor-intensive technology. Among the major constraints are access roads, appropriate landing facilities, and availability of adequate gear and other inputs. Future developments in the sector, aimed at promoting a locally-owned industrial fleet, and to create conditions for investments in processing infrastructure within the continent, would have to include ports suitable to the needs of the sector, strategically located with respect to the fishing areas and with the required handling facilities” (NEPAD, 2002).

“As of now, markets for artisanal fishery products are also extremely important in the African continent for both coastal communities, whose livelihood strategies are heavily dependent on fisheries, and inland populations, for which fish represents usually a cheap source of protein and nutrition compared to other sources.

Improvements to market infrastructure coupled with investments in connecting rural roads would reduce transaction costs with likely beneficial effects on both producer incomes (higher producer prices) and increased accessibility to fish and fish products for consumption by the general population (with lower consumption prices). Being built for general purposes, many African ports fail to meet the needs of artisanal fisheries, where the construction of small fishing jetties and docks could serve the many communities and villages along the African coast, thus creating poles of development that could easily link with national and regional markets” (NEPAD, 2002).

As an example, the commercial kapenta (*Limnothrissa miodon*) fisheries of Lake Kariba (potential of 8,000+ tons/year) and Cahora Bassa dam (potential of 8,000 metric tons/year) are important sources of protein for Southern Africa’s poor (see Chapter 7, Section 7.8.5, Impoundment Fisheries from Dams).

Another major problem where governments are failing on their own is in the sustainable management of Africa’s important inland and coastal artisanal fisheries. For instance

“irresponsible fishing (often as the result of dis-empowering artisanal fishermen during colonialism taking common property managed fisheries and turning them into open access unmanaged fisheries) in inland (and near shore coastal) waters results in capture levels that are often in excess of the stocking and recharge capacity. Africa gains much employment and income from lake fisheries as well as coastline artisanal fisheries on the high seas. Furthermore, the infestation of some inland lakes and waterways with aquatic weeds has reduced fish catches. The reduction of local diversity of fish populations by alien species may have serious consequences. There are severe problems with post-harvest handling, storage and distribution, which restrict supply to urban areas as well as access to overseas markets; they also keep incomes sub-optimal for fisher folk” (NEPAD, 2002).

Chapters 2, 4, 8 and 9 look closer into this issue and how fisher communities did and could be empowered to control access to and manage their resources in both coastal and nearshore inland waters. Resource and habitat/territorial tenure by fisher groups are key issues if success in this sector is to be achieved.

5.12.9 NEPAD, African Governments Overcoming Constraints to Agriculture

The New Partnership for Africa's Development (NEPAD) is a pledge by African leaders, based on a common vision, to come up with a program action to redevelop Africa (see Chapter 13, Section 13.14, NEPAD). Agriculture is to deliver broad-based economic advance through food security, income generation and diversified export growth. The first Conference of Ministers of Agriculture of the African Union, held in Maputo on 2 July 2003, examined the food security and agricultural challenges facing Africa, recommending that the “Comprehensive Africa Agriculture Development Program” (CAADP) (NEPAD, 2002) guide African governments in their agricultural development. The ministers decided to establish an African Common Market for basic food products—and to continue to address the root causes of the weakness in agriculture and the inadequacy of managing water and rural infrastructure (World Economic Forum, 2004). The CAADP was prepared by the UN Food and Agricultural Organization (FAO) in collaboration with the NEPAD Secretariat to promote interventions that best respond to the widely recognized crisis situation of African agriculture. It recommended a

“focus on investment into the following 4 mutually reinforcing ‘pillars’ that can make the earliest difference to Africa’s dire situation: (a) extending the area under sustainable land management and reliable water control systems; (b) improving rural infrastructure and trade-related capacities for improved

market access; (c) increasing food supply and reducing hunger, and (d) agricultural research and extension” (NEPAD, 2002).

The ministers also agreed to adopt fair policies and increase budgetary resources for agricultural development. The Summit of the Heads of State and Governments, also held in Maputo in July 2003, adopted a “Declaration on Agriculture and Food Security in Africa”. The Heads of State resolved to (World Economic Forum, 2004):

- Revitalize the agricultural sector through special policies and strategies targeted at small and traditional farmers in rural areas;
- Implement, as a matter of urgency, the Comprehensive Africa Agriculture Development Program (CAADP). African Union member states agreed to allocate at least 10% of national budgetary resources for implementation within five years;
- Ensure the establishment of regional food reserve systems, linked to Africa’s production, and develop policies and strategies to fight hunger and poverty; and
- Accelerate the process of establishing the African Investment Bank, which would give priority to investment in agricultural production.

The total outlay for the period 2002 to 2015 (including operations and maintenance) for the four pillars identified under the CAADP is US\$ 251 billion (all of Africa not just Sub-Saharan Africa), and is apportioned as follows (NEPAD, 2002):

- **Extending the area under sustainable land management and reliable water control systems:** Increasing the area under irrigation (new and rehabilitated), especially small-scale, from 11.6-13.5 million ha to 20

million ha and improving land management on the same area: US\$ 37 billion plus US\$ 31 billion for operation and maintenance;

- **Improving rural infrastructure and trade-related capacities for market access:** US\$ **92 billion** of which US\$ 62 billion would be for rural roads and US\$ 2.8 billion for trade-related capacities for improved market access. To protect infrastructure investments would require additional allocations for continuing operation and maintenance totaling some US\$ 37 billion over the period;
- **Increasing food supply and reducing hunger:** Raising the productivity of 15 million small farms through improved technology, services and policies: US\$ 7.5 billion. There is a “sub-pillar” on emergencies and safety nets requiring some US\$ 42 billion; and
- **Agricultural research, technology dissemination and adoption:** a total of **US\$ 4.6 billion.**

It is interesting that there is no talk of commercial agriculture. The fact is that judging from the analysis in this chapter, seeing significant increases in small-scale agriculture will be difficult due to physical and environmental constraints over much of Sub-Saharan Africa, the lack of appropriate technologies adapted to the small-scale farmer, as well as poor research and extension services. Meanwhile, the cities are swelling with young people fleeing the rural areas that have gone beyond their carrying capacities to support humanity and their livestock.

It would seem logical that a push to increase commercial agriculture in order to feed the urban masses should be a priority, but this is being ignored in favor of placing an emphasis on small-scale farmers. However, after 40 years of donor intervention in this area there are not many successes stories. Omotoso (2004) raises concerns that African governments are falling into the same old trap that

will be doomed to failure on its own. “The Accelerated Development in Sub-Saharan Africa – An Agenda For Action”, being pushed by the World Bank and apparently adopted by African heads of State fixes the development solution on the export of crops with less attention on food self-sufficiency and industrial development.

5.12.10 Industrialization, Food Security Versus Food Self-Sufficiency

USAID (2002) examined such issues in five countries; Ethiopia, Kenya, Rwanda, Mozambique, and Zambia. In each country, the bottom 25% of small-scale farm households is approaching landlessness, controlling less than 0.12 ha/capita. Even so, in none of the five countries do households in the bottomland quartile earn more than 50% of their total income, on average, from off-farm activities. The agricultural labor force is increasing faster than the area under crop cultivation and this appears to be very robust in all cases. These trends suggest that it will be increasingly difficult for farming alone to sustain the livelihoods of land-constrained households without substantial shifts in labor from agriculture to off-farm and non-farm sectors. During this process, there will be high payoffs to education, as the most highly skilled households have the best access to the well-paying non-farm jobs (USAID, 2002).

Any general and substantial increase in agricultural productivity and prosperity will depend on the development of non-agricultural sectors, the creation of jobs for the surplus rural population, and the consequent generation of expanding markets for farm products (Allan, 1965 *In:* de Vos, 1975). In Ethiopia

“officials believe that industrialization, not land reform, is the key to a better economic future for Ethiopia’s children” (Wax, 2006).

Food self-sufficiency is a peculiarly obtuse way of thinking about food security. There is no particular problem, even without self-sufficiency, in achieving nutritional security through the elimination of poverty (so that people can buy food) and through the availability of food in the world market (so that countries can import food if there is not an adequate stock at home) (Sen, 2002). This raises the debate over achieving a balance between producing food and cash crops as the best route to food security, following the principle of long-term comparative advantage rather than food self-sufficiency for its own sake (Maxwell, 2001 *In: Devereux & Maxwell, 2001a*). However, this also implies increased transformation of both food and cash crops, and other natural resources in Sub-Saharan Africa, as a spin-off, providing increased jobs through agro-industry that will also help take pressures off the lands by subsistence farmers by drawing many into the cities. By-products from agriculture such as textiles from cotton, transformed coffee and cacao, cooking oils, etc. can also become a major source of foreign exchange (Nana-Sinkam, 1995; Maxwell, 2001 *In: Devereux & Maxwell, 2001a*) taking advantage of Africa's comparative advantage in certain agricultural sectors, while importing food from other parts of the world (e.g., rice from Thailand) where it can be produced cheaper than in Africa. As French agronomist René Dumont (1966) believed, agricultural revolutions facilitate industrial revolutions.

In simple terms, if Africa's land is to continue to produce food and export commodities, the majority of the people, living beyond the carrying capacity of the land, must be pulled into urban sectors. Those people living on the land must be helped to maximize sustainable yields of their crops, while shortfalls, along the idea of Food Security, can be imported and bought with FOREX/cash generated from the transformation through African-based agro-industries. Land consolidation into economically viable units will need to occur in the many areas where subdivision has negated this possibility to date. It will be important to

identify the best agricultural land and help small-scale farmers on these lands adopt commercial technologies. Meanwhile farmers on marginal land, assuming the pressure can be taken off, and this is not yet evident, will need help in adopting improved fallow agriculture, integrating traditional and modern management systems adapted to the prevailing ecological and climatic conditions.

The transformation/beneficiation of Sub-Saharan Africa's raw products, from oil and minerals to coffee, cacao, cotton, timber, etc. in Africa can employ hundreds of thousands if not millions of people. The recent analysis by the Commission for Africa (2005) is a big proponent of the development of agro-industries on the subcontinent to fuel economic development and urbanization, South Africa being a good role model. Beyond this, Sub-Saharan Africa must be helped with telecommunications and entry into the Information Technology (IT) age, which can also help to relieve pressure on its over-used rural resources – especially its soils, pastures and wild lands. The movement into industrialization/urbanization will also be crucial not only to food security and maintenance of soil and pasture quality, but will probably also be critical in determining the future of the subcontinent's parks and game reserves, which are under tremendous pressure from the surrounding sea of poverty.

A growing number of newly industrialized and developing countries recognize that this has to be the way forward, the real issue being how fast to move and who pays. However, Sub-Saharan Africa must make sure that the worker receives an equitable share of the benefits and that adequate environmental controls are in place to protect the worker, the air, water, etc. Sustainable economic development as pursued by the South must foremost focus its efforts on meeting the developmental challenges, which are the causes of environmental degradation. In this connection, the first objective of sustainable development must be to eradicate poverty (Nana-Sinkam, 1995).

5.13 CONCLUSIONS

Often thought of as tropical, approximately 70-75% of Sub-Saharan Africa falls within the savanna biome. Over 40 years of Western donor input has failed to bring a “Green Revolution” to Sub-Saharan Africa due to major soil and climatic constraints in savanna and tropical lowland forest environments, including soil moisture (in the savanna biome), and in appropriate research.

5.13.1 Colonial and Post Independence Impacts on Agricultural Production

Although climate change (e.g., global warming) is believed to be a contributing factor, desertification is thought to be primarily man-made in origin. Although induced by rural Africans, habitat destruction and desertification can be linked to the legacy of the colonial past. This has continued into the post-independence era of the last 40 years as the result of inappropriate policies adopted by a political elite often with stronger ties to the colonial metropole than to their own people, often trained and educated in colonial policies and approaches to exploitation. This includes the following:

- The introduction of improved medical and veterinary care resulted in an explosion of humans and livestock in the 20th century. Keeping the majority of Africans backward and uneducated left them stuck in a time warp of technologies and tradition. Mono-culture cash crops for export as raw products were encouraged to stimulate the economies of the “mother country” without an understanding of the physical and chemical limitations of the soils. This took away Africans from and/or diminished traditional soil management systems such as long fallow periods, intercropping, green and animal manure, crop rotation, etc.

- Colonial powers and post-independent governments failed to recognize traditional controls over access to natural resources, management and land tenure systems. Rural communities were and continue to be disenfranchised through centralized control over land and associated resources. This resulted in the creation of “Open Access Resources” as opposed to “Common Property Resources” that could not be controlled or sustainably managed by isolated bureaucrats alienated from the rural populace, with policies that favored the needs of Europe and increasingly America.
- The inappropriate use of technologies such as the ill thought out placement of boreholes in rainy season dispersal areas, took extensive transhumance pastoralists into intensive management regimes without the concomitant training (see Chapter 6). The construction of dams ignored the downstream impacts on traditional floodplain ecosystems that provided a diverse array of resources and a more complete diet than irrigated mono-culture rice economies.
- Creating modern nation states with artificial boundaries served to inhibited mobility, especially of nomadic pastoralist, necessary to assure the sustainable use of savanna resources. Sedentarization policies exasperated this problem (see Chapter 6).
- Creating “Sherwood Forests” in the form of parks and protected areas for rich overseas tourists, today in the name of preserving biodiversity, and settler plantations cut Africans off from the diverse array of natural resources, which they obtained from these natural systems. This compressed Africans onto land that could not sustainably support them and their livestock.

Colonial powers, post colonial governments and proxy-colonial powers in the form of Western donors, International Finance Institutions (IFIs) and Western NGOs saw man-made agricultural systems (e.g., agro-forestry, crop farming, fish culture) and livestock, through failed “integrated rural development”, as the cure-all for rural Sub-Saharan Africa’s ills. Until recently, there was little regard for implicating Africans in the sustainable management of other natural resources (e.g., forests, wildlife, fisheries, minerals) that are often the best “land uses”, both economically and ecologically on what are marginal agricultural lands, especially over the vast savannas of the subcontinent. Little or no research was undertaken into improving yields of traditional African cereals such as sorghum and millet, in favor of maize that is not as well adapted to Africa’s chronically low rainfall areas that constitute the majority of Sub-Saharan Africa.

Agricultural prices were/are controlled both globally and locally to the disadvantage of the small-scale farmer providing cheap resources to the “mother country”, to corrupt marketing boards and/or to provide cheap food to the urban populace as a means of preventing civil unrest that assured/assures the *petite bourgeoisie* and their colonial masters remained/remain in power while controlling resource economies to their advantage. Structural adjustment policies (SAPs) (e.g., decreased subsidization of agricultural inputs, health and education, and declining agricultural research/extension) (see Chapter 12) and foreign aid (see Chapter 11) were/are used to keep Sub-Saharan African economies in a dependent relationship with the West. Africans remain uneducated and easily manipulated, while assuring the continued flow of cheap raw products to stimulate Western economies.

5.13.2 Net Results of Colonial and Post Independence Periods on Sub-Saharan Agriculture

Africa is in a crisis with regards to agriculture and the ability to feed itself. A human population that increased 5.5-6.5 times in the 20th century with projections, even with HIV/AIDS, of increasing another 2.4-2.8 times by 2050 to nearly 1.8 billion people has resulted in a continent that appears to have exceeded the carrying capacity to feed itself as currently managed. Along with this explosion in people, there has been a concurrent explosion in livestock (see Chapter 6 on livestock and boreholes). It is unlikely that Africa will attain food self-sufficiency alone, and thus will have to rely on a combination of food self-sufficiency and security strategies. These in turn rely on both increasing food production on the continent, as well as on alleviating poverty, in order to allow people to buy their food in a global market, as, for instance, it may be cheaper to import rice from Thailand than to produce it locally.

Within a couple of generations, there has been a major loss in knowledge of traditional soil management that had been passed on for generations.

Poorly placed and/or mismanaged boreholes resulted in massive over-grazing during the dry season in rainy season grazing areas especially along the Sahelian/Saharan borders causing desertification (see Chapter 6), while critical dry season grazing areas and recession agriculture along floodplains were wiped out from decreased downstream flooding due to dams built to support unsustainable irrigation technologies as formally practiced (see Chapter 7 on dams). In Sub-Saharan Africa in the 1980s for every hectare brought under irrigation, another went out of production due to salinization and water logging.

The exploding population and land hunger on the continent has reduced or eliminated the traditional 20-year bush fallow cycle that allowed soils to rejuvenate their productivity. This has resulted in mining the productivity of soils, which had been sustainably managed for centuries. At the same time, expanding populations moved into areas that are marginal for agriculture. Extensification of agriculture into marginal areas, often dry season grazing areas for livestock and wildlife, is putting small-scale farmers in conflict with other land users, which is resulting in both internal and international civil strife. There was massive deforestation in Sub-Saharan Africa's forested savannas as these "marginal areas" were converted into unsustainable agriculture. It is estimated that by 2010, Sub-Saharan Africa agricultural fallow periods will have disappeared in 20 countries and will constitute less than 25% of arable lands in another 29 countries.

The loss of forests has resulted in farmers using crop residue and even manure as a source of energy. In the past, crop residue provided an important source of fodder for livestock during the dry, while manure, during feeding in the fields, provided an important soil amendment to maintain soil productivity. Thus, much of Sub-Saharan Africa has been thrown into a tail spin from which it is having a difficult time escaping

In the increasingly degraded Sahelian zone, especially on the border between the Sahara Desert and the Sahel, from Senegal to northern Nigeria to Darfur, Sudan, the collision of southern moving pastoralists with northern moving farmers has contributed to major conflicts. This has resulted in massive losses of life, hundreds of thousands of Internally Displaced Persons (IDPs) and a decreasing ability of rural people to provide for themselves and/or growing urban centers. Only 4-8% of the 5.3 million km² area in the Sahel is suitable for agriculture. Similarly, the Mau Mau uprising in Kenya and more recently Maasai/Kikuyu conflicts, the Rwandan genocide, the wars in Ethiopia and the Ivory Coast and to

some degree the eastern DRC, are believed to have been/be closely linked to over-population and people trying to sustain themselves on an inadequate resource base – especially land.

Due to the extremely low value received for crops by small-scale farmers, there is an inability to afford inputs such as fertilizers or pesticides, which in some areas might have helped maintain the sustainability of the soils and increased crop yields. The reluctance of small-scale farmers to reinvest their profits back into the land, especially into soil and crop protecting measures such as fertilizers, pesticides and soil conservation measures can also be attributed to insecure land tenure from centralization begun under colonialism and finalized by independent African states. In much of the savanna area with marginal soils, the cost of inputs versus the increase in crop yields may not be economically viable.

The nutritional status of Africans has been declining due to limited access to their natural resources and loss of traditional management systems. The creation of “Open Access Resources” has placed rural Africans into a “mining mode”, where natural resources, including soil, are seen as short-term assets that if locals do not take advantage of, outsiders will expropriate. In collusion with the mother country and its private sector, political elites have expropriated rural Africa’s wealth to the capital and overseas, with little or no reinvestment in the people or physical/social infrastructure, and with little or no circulation of money through thousands of hands from the rural areas to African capital as a means of creating a consumer economy.

There has been a failure to industrialize and thereby transform Sub-Saharan Africa’s rich raw natural resources as a means of obtaining added value to stimulate the subcontinent’s economies and to employ the mass rural-urban migration that began in the latter part of the 20th century. This rural-urban

migration resulted/is resulting from a combination of poverty, declining agricultural production, declining hectares of land/farmer and continual drought, typical of this subcontinent and predicted by some to increase with global warming. The net result is that human and livestock populations have become increasingly out-of-balance with their environment, stuck in Phase I subsistence agricultural and pastoralism with little or no urban economy. Without an alternative, poorly educated urban-based Africans work for subsistence wages as laborers “boys” for the few African urban elites and/or for the large expatriate community composed of Western donor “experts” and businessmen. Seeing no future in the cities, many of these poor urban-based Africans have reinvested/reinvest what little wealth they accumulated back into the rural areas, from whence they came, in the form of livestock or extensive agriculture through remittances to their rural families. Thus, inappropriate urbanization has contributed to and compounded an already growing problem, the mining of Sub-Saharan Africa’s rural wealth and the accelerated degradation of its natural systems and/or their conversion into man-made agricultural systems, which over most of subcontinent are not the best land uses (see Chapter 9, Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

The fact that Africans are kept in a downward spiraling level of poverty and nutrition, are separated from their families and are living between urban centers or settler plantations and rural farms/homelands has resulted in a breakdown of traditional value systems. This has greatly contributed to the current HIV/AIDS epidemic. This epidemic has had a major impact on women, the primary contributors to rural agricultural production in Sub-Saharan Africa. This in turn has resulted in declining agricultural production and a declining nutritional status especially among children, as well as a further breakdown in traditional social structures.

The politicization of land reform in former settler colonies (e.g., Zimbabwe) risks to further decrease Sub-Saharan Africa's ability to feed itself. Land reform may be politically necessary to overcome past injustices. However, as practiced in Zimbabwe, commercial farms have been given to subsistence farmers or in many cases to non-farming politicians and other connected elites. Uneducated and living a subsistence lifestyle that requires large families, both to work the farms and to assure security in old age, giving subsistence farmers more land is only a temporary fix for one generation. Land hunger will return, as the large progeny from current farm families will not have access to economically viable plots. Per capita land has now declined from about 0.5 ha/person to less than 0.3 ha/ person over the last 30 years in Sub-Saharan Africa. Subdivisions of land will occur and rural Africans will be back to square one; living in poverty and on land that is too small to support a nuclear family. It also needs to be clearly stated that a farm, which supported one commercial farmer and his family will not result in a middleclass among 100's of families who might receive such a farm under land reform/land claim processes.

Land reform as practiced by Zimbabwe is dealing with symptoms rather than really solving Africa's food crisis problems – especially feeding the increasing urban masses. In fact, it is dangerous, since feeding the urban masses is critical to maintaining political stability on the Continent. As currently practiced, land reform is actually decreasing the ability of Africa to feed these urban masses since it is taking commercial land out of production. Making Africans increasingly food-aid-dependent is in the interest of Western donors and NGOs who may wish to control Sub-Saharan Africa politically and economically in order to access cheap raw products they need to stimulate their economies, and/or to impose their value systems by creating more parks and protected areas in the name of biodiversity. This would further disenfranchise, impoverish and alienate rural Africans from their natural resources, which in some cases may result in further

eco-genocide. As importantly, a global grain deficit over the last few years and increasing conversion of grain to ethanol/bio-fuels could eventually prevent the world from feeding Sub-Saharan Africa, especially if global warming continues to result in a reduction of global food production. Africa must start planning for its own future, rather than allowing others to plan and dictate to it.

5.13.3 Possible Way Forward

How can Africa escape this downward spiral in agricultural production? The following may provide some ideas for “The Way Forward”, but only Africa can implement these ideas and make them successful within the socio-cultural and political contexts of the Continent.

The 27% of Sub-Saharan Africa that is conducive to commercial agriculture that can feed the urban masses needs to be identified. Where land is not over-populated or already degraded, a continental-wide plan needs to be developed to assure that this land can help Africa feed itself, operating it on a commercial basis. Unfortunately, much of this land is already heavily populated (e.g., Rwanda, Burundi, Southwest Uganda, Kikuyu Highlands of Kenya, Ethiopia) and experiencing severe soil degradation. Coastal countries such as Ghana and Ivory Coast, with high potential lands are beginning to feel the pressure of desertification further north, with mass migrations of people southward in search of land. Other potential high agricultural yield areas are in major conflict with wildlife and traditional pastoralism, such as the high altitude grasslands Tanzania and Kenya. Only the people of these countries can decide what direction these land uses will take, as natural areas or food producing areas.

Sub-Saharan Africa must develop regional markets for these grains and get away from seeing subsidized handouts from Western donors as an alternative to Africa

being able to feed itself. This may require joint-ventures between the private sector (e.g., commercial white African farmers, multi-national agro-industry) and small-scale farmers along with the use of genetically modified (GM) crops and fertilizer/pesticides to achieve this goal. Pilot programs, creating partnerships between white commercial “mentor” farmers and small-scale farmers, are beginning to take hold in South Africa and need to be encouraged across the continent where such potential exists.

In some cases, it may be more affordable to import certain grains (e.g., rice) in the short-run and maybe even in the long-run. In some cases, cash crops (e.g., tobacco, cocoa, tea, coffee, etc.), especially if they are transformed/beneficiated in Africa, may provide viable alternatives to food self-sufficiency through providing cash for food security, giving Africans in both urban and rural areas the ability to buy their food regardless of its origins. Thus, Sub-Saharan Africa’s policies must lead to a blend of food self-sufficiency combined with food security, not one or the other.

Irrigation and “Green Revolution” technologies may be of some help, but must be carefully integrated into national plans to assure that they do not destroy traditional ecological and production systems (e.g., by dams associated with irrigation) and do not result in further soil degradation, especially salinization. Where dams have destroyed floodplain ecosystems (e.g., Senegal River Valley, Zambezi Delta), controlled flooding to bring these systems back into production should be strongly considered. Water for irrigation will have to fit into other needs such as the partitioning of available water for industrial and potable needs, and in some cases the sharing of this resource between countries.

There is a crying need to support agricultural research and extension services to the estimated 70 million smallholder families in Sub-Saharan Africa, many on

marginal lands, including appropriate and cost-effective technologies such as small-scale irrigation technology, the use of locally manufactured phosphate fertilizers, and other soil conservation technologies that link traditional knowledge to modern concepts.

Agricultural and land use intensification will be necessary to help preserve the environment, including nature reserves, wetlands, fragile areas, game reserves and mangroves. On the medium/low potential lands constituting 47.5% of Sub-Saharan Africa, the cost of inputs such as fertilizer versus increases in yields may not be not cost-effective. Lower cost Low External Input (LEI) technologies such as Integrated Nutrient Management (INM) may be required in such cases. There is a need for agricultural extensionists and anthropologists to work with African elders to capture traditional knowledge about INM (e.g., traditional use of fallow, legumes, crop rotation, green and animal manure, inter-cropping, etc.) and other natural resources, both technically and socially.

Research needs to investigate enhancing production of traditional drought tolerant grains such as developing improved varieties of sorghum and millet, as well as sustainably managing the soils on which these crops are produced.

The current population of Africans farming, an estimated 60-70% of the labor force, is not sustainable. Young Africans are abandoning the impoverished and environmentally degraded rural areas for the bright lights of the urban slums of Africa's increasing mega-cities, looking for new opportunities that are few and far between. Today, they are trading one place of poverty for another. Most are uneducated and ill-prepared to take advantage of the globalization process.

African governments and the international community must take advantage of this movement away from the land. The land cannot continue to support the majority

of the continent living rural subsistence life styles (nor could Europe or America), without further jeopardizing soil quality and thus agricultural production as well as the continent's remaining natural areas, which are becoming "hard-edged" "Islands of Wildlife" surrounded by people, the opposite of what existed at the beginning of the 20th century. However, to take advantage of this movement, an emphasis must be placed on education at all levels, primary, secondary and tertiary, to allow Africans to join a global economy in these urban settings.

As a part of this educational program, there is also a need to develop agricultural training and "Future Farmers of Africa" programs in primary and secondary schools for those youths who choose to remain in rural settings. In addition, taking advantage of Africa's racial diversity, as young Africans graduate from tertiary agricultural programs there is a need to develop programs with commercial farmers and agro-industries to have them "apprenticed" on these farms until they can run and manage such operations, from planning crop production to managing farm labor. Also, technologies such as drip irrigation may have to be adopted to make these processes sustainable. Once again, South Africa has pilot programs moving in this direction that the rest of Africa should emulate.

Land reform must be de-politicized in Southern Africa to assure that commercially viable agricultural lands can continue to feed the region.

It has also to be recognized that in the majority of Sub-Saharan Africa's savannas will never be a breadbasket for the continent due to physical and chemical limitations of the soils, and vagaries of the climate (e.g., low and erratic rainfall, high temperatures and high evapotranspiration rates). One has to take advantage of the best land uses in these savannas such as wildlife, forestry, fisheries, pastoralism and in some cases long-fallow agriculture possibly linked to INM. In

addition, training has to be provided to rural Africans to sustainably manage these resources.

The ownership of natural resources and land should be devolved back to the rural Africans. In addition, the pros and cons of communal versus individual ownership property and associated resources should be carefully assessed within the framework of rural African societies (see Chapter 9, Section 9.7.2.1, Devolution through policy reform, land and resource tenure) and as a means of ensuring the ecological integrity of these areas. Dealing with land tenure and taking both land and natural resources out of corrupt and inefficient governments is considered critical to sustainable resource use and biodiversity. The government's role then becomes one of facilitator, advisor and extensionist to rural communities as opposed to dictator and policeman. This step, though it is happening, is far from being successful, since many poorly paid bureaucrats live more from the resources of rural Africans than from their own low salaries. They are thus reluctant to "let the resources go" back to their rightful owners.

In turn, rural Africans should be helped to start their own "community-owned" companies (e.g., ecotourism, safari, agricultural, etc.) that fit into their socio-cultural framework and which assure that the majority of net profits stay within rural Africa, thereby serving as a catalyst for development. This will help create a consumer society and healthy children capable of learning and able to afford an education that will allow them to fit into a global society, helping to take pressure off the rural resource base. These "companies" can pay taxes like any private sector. The shareholders of the companies, the heads of households, can also pay taxes if income is distributed at this level. This will negate the felt need by African governments to take the value of these resources directly (income paid directly to governments by expatriate tourism, safari hunting, logging, oil and mining companies to governments that bypasses rural stakeholders), a major

reason that rural Africans remain in a perpetual state of poverty on the richest continent in the world.

This implies a win-win relationship with the West in which they introduce their technologies through the Western private sector to help Sub-Saharan Africa industrialize. The raw products on the subcontinent would be transformed in factories built in carefully selected urban centers of Africa that can take advantage of the regional populace without placing undue pressure on local resources such as water, forests and wildlife. Agriculture can serve as the basis for this technological revolution. In the 21st century, Sub-Saharan Africa must go through the same urbanization, industrialization and Information Technology (IT) evolution experienced by Europe and North America in the 20th century, where for instance less than 2% of the people in America fed the majority living in urban centers. If not, in addition to the future of civil society, Africa's natural resource base and revered mega-fauna will be in jeopardy. Anarchy will reign on the subcontinent and civil wars over scarce resources will increase, while mega-cities will be plagued by crime (e.g., Dakar, Lagos, Abidjan, Nairobi, Johannesburg, etc.) and any hope for Foreign Direct Investment (FDI) will be lost, as capital and technology flee the Continent.

Trade barriers, dumping subsidized food and other products in Africa, and other Western approaches that keep Africa marginalized must be halted.

Finally, helping Sub-Saharan Africa to create an educated middleclass will result in smaller, healthier and better educated families, decreased population growth rates, which, are currently exceeding increases in agricultural production, decreased rates of HIV/AIDS and a citizenry that holds its leaders accountable.

Capitalism is based on maximizing profits at all costs and in creating win-lose relationships with the rest of the world. Until now, Western Capitalism has failed the developing world every bit as badly as communism. Africa's New Partnership for Africa's Development (NEPAD) asks both Western governments and their private sector, in return for appropriate policies and good governance, to turn from exploitation for short-term gains to investment in a win-win relationship that in a global society will give Africans and their natural resources, especially their unique mega-fauna, a hope for the future.

Many of these latter issues are discussed in future chapters.

Chapter 6

6.0 HABITAT DEGRADATION, LINKED TO COLONIAL/POST-COLONIAL POLICIES AND WATERING POINTS/BOREHOLES IN SUB-SAHARAN AFRICA

“When Will They Ever Learn, When Will They Ever Learn”!
 (from rock song over boreholes in Chad *In:* Flack, 2003).

The next three chapters look at the impacts of some technological interventions, which are inappropriately used on the African continent, namely boreholes, dams and sewage in coastal areas. In terms of boreholes and sewage, misuse tends to be out of ignorance. The misuse of dams, however, generally takes place with a clear understanding of their catastrophic impacts on people and the environment. This is because dams mean big money for all stakeholders, except for the rural poor, who lose out considerably.

In the arid areas, comprising about 48.2% of Sub-Saharan Africa (Table 6.1), livestock production is one of the most appropriate types of land use (Swallow & McCarthy *In:* McCarthy, Swallow, Kirk & Hazell, 2000). This includes the savanna biome that makes up between 70-75% of Sub-Saharan Africa and cuts across these classifications of aridity. It is found in areas with rainfall ranging from a lower limit of 350 mm rainfall/year grading into desert (Sholes, 1997 *In:* Cowling, Richardson & Pierce, 1997) to an upper limit of about 900 mm of rainfall/year (Reilly, *pers. comm.*) grading into woodlands and open semi-deciduous forests (Sholes, 1997 *In:* Cowling, *et al.*, 1997) that are best used for wildlife and livestock (see Chapter 5).

Table 6.1: Land area in Africa by aridity zone (millions of km²)

	North	Sahel	South	Others	Total	Sub-Saharan	% Sub-Saharan
Hyperarid	3.85	2.76	0.08	0.0	6.70	2.84	11.7
Arid	0.98	3.49	0.54	0.03	5.04	4.06	16.8
Semi-arid	0.37	3.04	1.59	0.13	5.14	4.76	19.7
Dry sub-humid	0.15	1.50	0.82	0.22	2.69	2.54	10.5
Humid	0.09	2.60	1.28	6.13	10.10	10.10	41.7
Total	5.45	13.39	4.31	6.51	29.66	24.21

Le Houerou (1989 *In:* de Haan, Steinfeld & Blackburn, 1997) estimates that in Africa there are as many as 3,500 plant species on which the continent's herbivores feed, compared to less than 150 species on which humans depend.

African rangelands evolved under indigenous multi-species systems typically carrying 15-25 ungulate species (Cumming, 1994 *In:* Bond, Child, de la Harpe, Jones, Barnes & Anderson, 2004 *In:* Child, 2004). Though the rangelands had been exposed to domestic livestock for about 2,000 years, it took about 100-150 years for well under 10% of the herbivore biomass on Sub-Saharan Africa's savannas to be in the form of wildlife. This was the case by the 1980s (Cumming & Bond, 1991 *In:* Bond, *et al.*, 2004 *In:* Child, 2004). Outside parks and protected areas over most of Africa, wildlife had no value to the commercial farmers until the mid-1960s. For most rural Africans this is still the case, though Community-Based Natural Resource Management (CBNRM), taking off around 1980 in Southern Africa, began to provide some benefits in communal areas in an attempt to promote conservation through valorization of the resource (see Chapter 9, Section 9.4, ORIGINS OF CBNRM IN AFRICA). In fact, in many instances, livestock has been (e.g., white commercial ranchers in colonial Zimbabwe) and continues to be (e.g., Botswana) subsidized, providing it with an artificial economic advantage over wildlife as a land use.

Many Western range management experts have failed to understand the ecological and cultural constraints of increased livestock production in the Sahel and dry savannas of Africa. Both international and national politics often result in inappropriate decisions being made in the name of “development”, with the result that habitat is degraded and people become poorer rather than richer because of these interventions. This is especially the case in attempts to turn nomadic cultures, adapted to the ecology of their region, into sedentary lifestyles as a means of controlling what might be considered possible radical elements of society.

Artificial watering holes for both livestock and wildlife have been placed in African savanna environments, often in traditional rainy season dispersal areas where water is the key limiting factor to herbaceous production during the dry season. This has been done without fully understanding the impact on the habitat, transhumance or the inter-relationships between species. In many cases, the net result has been: 1) degraded habitat, 2) a decrease in biodiversity, 3) destabilization of wildlife populations by water-dependent ungulates and elephants displacing rarer water-independent species, 4) increases in predator impacts on prey populations, 5) worsening animal mortality during drought and 6) extensive pastoralists being forced into an intensive management system for which they are ill-prepared, with the net result that they become sedentary around artificial water holes. In very low rainfall areas, very often for 20 km around the watering point, the vegetation will be denuded, creating a piosphere defined as a radiating zone of attenuating animal impact away from a concentrator (e.g., mineral licks, bedding grounds, etc.). Thus, a poorly placed watering point can result in a reduction in vegetative cover, changes in soil chemistry and soil erosion. If the artificial water holes are close enough together, this can result in human-made desertification. This is the case for livestock and to a lesser degree wildlife populations.

Oldeman, Hakkeling and Sombroek (1991 *In: de Haan, et al., 1997*) estimate that 680 million ha of rangeland world-wide has become degraded since 1945, while Dregne, Kassas and Rozanov (1991 *In: de Haan, et al., 1997*) argue that 73% of the world's 4.5 billion ha of rangeland is moderately or severely degraded.

6.1 IMPACTS OF BOREHOLES ON PASTORALISM

6.1.1 Water and Savanna Ecology

Across the savannas of Africa, natural vegetation (range and fallow), crop residues and water were/are the main resources used by pastoralists. Water is of particular importance because it largely determines the value of other resources, such as the grazing resources of annual and perennial grasses and woody vegetation. It is the limiting factor determining how long livestock can remain in an area. African rangeland (at least many species within it) is very resilient and capable of rapid regeneration during the rainy season, despite being trampled or grazed down to the surface.

Savannas have a number of limiting factors, specifically the nitrogen and phosphorus compounds available to plants. These limitations are exacerbated by dry periods, as water is necessary for leaching of chemical inhibitors from leaves before the microbial breakdown of the detritus layer that recycles nutrients can take place. These inhibitors are adaptations to browsing defense (e.g., tannin¹⁰⁷ build-up in mopane leaves from over-browsing by kudu) (Scholes, 1997 *In: Cowling, et al., 1997*).

¹⁰⁷ As kudu, impala or other browsers place more pressure on woody plant species, tannin builds up in the leaves. Tannin kills bacteria in the stomach, which are necessary to digest leaves. In extreme conditions, when an area is over-browsed, tannin levels may be so high that sufficient stomach flora are killed, resulting in the animal starving to death (Thomson, 2003).

Besides limiting factors, savannas also have a number of drivers such as fire, with rainfall being the primary force. It has been demonstrated that a linear relationship exists between rainfall and the above ground primary production of up to 900 mm rainfall/year. About 50% of the primary production in savannas is below ground. In Southern Africa's savannas, net primary production is 500-1,500 grams/m²/year of which 90% or more is typically produced by grasses. Depending on the situation, however, herbaceous layer production can vary from 5-95% (Scholes, 1997 *In: Cowling, et al.*, 1997). Hulme and Kelly (1993 *In: Swallow & McCarthy*, 2000 *In: McCarthy, et al.*, 2000) show that 83% of the variation in aerial extent of the Sahara between 1980 and 1989 was explained by variations in annual rainfall. Studies conducted at field sites in Kenya (Ellis & Swift, 1988; 1992 both *In: Swallow & McCarthy*, 2000 *In: McCarthy, et al.*, 2000), Senegal (Hanan, Prevost, Diouf & Diallo, 1991 *In: Swallow & McCarthy*, 2000 *In: McCarthy, et al.*, 2000) and Mali (Hiernaux, 1993) found that herbage yields depended almost completely on rainfall.

Likewise, the regional production of large mammalian herbivores is proportionally related to rainfall total, though total biomass is two to three times greater in regions of high soil nutrient status than in areas with low soil fertility (Owen-Smith & Danckwerts, 1997 *In: Cowling, et al.*, 1997). This relates back to grass and vegetation production. Finally, in the savannas, disease epidemiology is often considered a response to drought situations (e.g., anthrax) as a means of protecting the overall health of the ecosystem.

6.1.2 Carrying Capacity and Sub-Saharan African Savannas

Linked to rainfall and climate, pasture productivity is variable and the theory of constant carrying capacity is no longer considered valid (Moore, Bertelsen, Diarra, Kadio, Cissé & Wyeth, 2000). Adams (2003 *In: Adams & Mulligan*,

2003) believes that due to the continuing fluctuation in climate and thus available fodder from year to year in the semi-arid rangelands of Africa, the concept of carrying capacity is only relevant in social or economic terms rather than in ecological terms relating to animal and plant densities.

We must also consider here the Eurocentric preoccupation with maintaining the vegetative component of savannas, especially grasses, resulting in what to Africans and many ecologists has resulted in incomprehensible no-burn policies. Europeans, coming from high rainfall areas, were/are accustomed to high grass and vegetative cover year-round, except during extreme droughts. In African savannas, the real value of grasses takes place over a brief period of weeks or months following inconsistent rainfall events. Grasses, having evolved within these “events”, are however also in an entirely intact state during droughts, when all species are present in other dormant life stages (e.g., seeds, geophytes¹⁰⁸).

Thomas and Middleton (1994 *In: de Haan, et al., 1997*) show that arid regions contain dynamic and highly resilient ecosystems, with a strong capacity to regenerate rapidly when the rains return.

“The new paradigm in range management for dryland Africa is based on the ‘nonequilibrium ecological theory’ in range ecology” (Ellis & Swift, 1988; Westoby, Walker & Noy-Meir, 1989; Niamir-Fuller, 1996 all *In: Grell & Kirk, 1997 In: McCarthy, et al., 1997*). “This theory recognizes three main characteristics of arid ecosystems: ecological variability, unpredictability, and resilience” (Grell & Kirk, 2000 *In: McCarthy, et al., 1997*, Excerpted with permission from the International Food Policy Research Institute).

Scoones (1995 *In: Cullis & Watson, 2005*) raises the concept of equilibrium and non-equilibrium environments. Equilibrium environments tend to be in more

¹⁰⁸ Sub-surface portions of perennial grasses that can withstand drought conditions until the next rains.

temperate climates where rainfall and thus vegetation are more predictable, as is carrying capacity. Exceeding carrying capacity can result in a negative impact on vegetation. Non-equilibrium environments, as in the savannas of Sub-Saharan Africa, tend to have highly fluctuating rainfall and thus carrying capacity:

- Drought (rather than stocking numbers) determines livestock numbers and vegetation status while grazing has a limited effect on grass production over time, making permanent degradation unlikely.
- Flexible movement is crucial to maintaining the productivity of African rangelands, which varies greatly over space and time.
- African pastoral production systems are geared towards a number of different livelihood objectives, which include milk production, meat, manure, draught power and transport. Interventions are aimed at boosting single outputs (e.g., meat), using simplistic management tools (e.g. fixed carrying capacity) as part of standardized models (e.g., ranches) that are unlikely to work.
- Communal rangelands are often under-valued for the multitude of products/resources that are harvested in addition to livestock, including assets such as wildlife, wild foods and medicines. This makes them up to twice as productive/ha than a single use cattle ranch.

“Defining conditions of land degradation under a non-equilibrium theory is more difficult than under an equilibrium one. Remote-sensing work has found that inter-annual variations in rainfall and vegetation structure are so high that they require decades-long monitoring to detect expansion or contraction of the Sahara” (Tucker, Dregne & Newcomb, 1991 *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

More recent research (Ellis & Swift, 1988; Behnke, 1997 both *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000) has provided support for the following arguments:

- The scale and magnitude of persistent environmental decline in dryland Africa has been overestimated.
- The role of livestock grazing in these changes has been overestimated.
- The pattern of anthropogenic land degradation is much more severe around permanent settlement sites than it is in open rangelands because of concentration of pressure (deforestation, over-cultivation, and over-grazing) (Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000).

Cullis and Watson (2005) suggest that the mobility afforded livestock on communal rangelands is more conducive to sustainable range management in the highly variable rainfall of Sub-Saharan Africa's semi-arid and arid areas than fencing or permanently settled areas that reduce and/or eliminate this mobility and can result in various phenomena, such as bush encroachment. Bush encroachment may be defined as

"the suppression of palatable grasses and herbs by encroaching woody species often unpalatable to domestic livestock. Therefore, bush encroachment reduces the carrying capacity for livestock" (Ward, 2005).

In the 1980s, the principal author visited a missionary friend in Linguere, Senegal, on the edge of the Ferlo during the peak of a drought. The ground was barren of any grasses with little or no wildlife to be seen. During the next year, the rains were prolific and what had appeared to be desert the year before was now covered in grasses and blooming bush, lush with francolin and warthog that had been virtually absent for years.

The concept of fixed carrying capacity in savanna environments has been disproved. De Haan, *et al.* (1997) give an example of a program in Senegal undertaken by GTZ that proved this point. Six plots of 200 ha each with fixed stocking rates were monitored for 12 years. The fixed stocking rate concept proved incompatible with the highly variable rainfall and thus forage, resulting in stocking rates being balanced with forage in two of the 12 years, three years being over-stocked and four years being under-stocked: "...the impact on vegetation was more negative than positive, owing to under-utilization, a decline in quality of pasture, and a thinning out of drought-resistant fodder species. Third, while animal production was good in the best years, animal vulnerability increased in bad years". This demonstrated the limits of the concept of carrying capacity in a system not at equilibrium and the difficulties of applying a closed system model over large areas, the reduction in traditional animal mobility and the reduction in symbiotic relations between herbivores and the plant community that occurs in an open system (de Haan, *et al.*, 1977).

6.1.3 Traditional Pastoralism in Sub-Saharan Africa

"The term 'pastoralist' is defined as a mode of production where livestock make up 50% or more of the economic portfolio of a smallholder" (Sandford, 1983 *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000). "The term 'transhumance' refers to regular seasonal movements of livestock between well-defined pasture areas (dry to wet season, or low to highland). It can cover a wide range of pastoral production systems, ranging from fully transhumant systems, such as among the northern Mauritians and Namibians, to systems such as used by the Nilotic tribes of east Africa, the Berber of the High Atlas, and herders in Morocco and Ethiopia. Transhumance also applies to settled populations who send their livestock short distances to pasture, such as in Zimbabwe. All these systems have several elements in common:

- They rely on common property (pastures, forests, and natural waters).

- They normally occupy arid lands with less than 400 millimeters of annual rainfall.
- Mobility is managed by herders, rather than by fencing" (*In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

The recognition of the importance of mobility for pastoral systems is not new, but what is new is a convergence of several scientific fields (ecology, anthropology, economics and institutions) into a more or less holistic paradigm (Niamir-Fuller, 2000 *In: McCarthy, et al., 2000*). Pastoralists traditionally used mobility and other herd management strategies, adapting to seasonal and erratic rainfall of the savannas (Moore, *et al.*, 2000; Swift & Hamilton, 2001).

"The evidence shows that there is no sustainable alternative, economically or ecologically, to the pastoral herders' opportunistic strategies for managing natural resources in arid and semi-arid zones" (Behnke & Scoones 1991; Behnke, Scoones, & Kerven, 1993; Grell, 1994; Scoones, 1995; Thébaud, Grell & Miehe, 1995; de Haan, 1996; de Haan, *et al.*, 1997 all *In: Grell & Kirk, 1997 In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

"The classical paradigm for livestock development in Africa, based on sedentarization, privatization and intensification, has, after 20 years, benefited only a very small minority of elite pastoralists...This new paradigm postulates that the greater the unpredictability and variability of a natural resource, the more suited it is to being held and managed communally...The new paradigm not only argues that transhumance is not an archaic remnant of the past, but even asserts that it is a necessary precondition to sustainable development in arid lands" (Niamir-Fuller, 1996 *In: Grell & Kirk, 2000 In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

Thus, "where rural producers live in high-risk environments, such as drylands, and where income streams are uncertain, communal-property systems may be more appropriate as they allow access to other areas: tenure systems that allow flexible and mobile response

to uncertainty provide insurance against environmental risk” (Moorehead, 1994 In: Grell & Kirk, 1997 In: McCarthy, *et al.*, 1997, Excerpted with permission from the International Food Policy Research Institute) (see Chapter 5, Section 9.7.2.1, Devolution through policy reform, land and resource tenure).

“In fact, the drier the ecosystem is, the greater is the incentive to manage the natural resource communally. In arid lands, uncertainty is high, and the risks of production and survival are higher. The risk burden is too much for an individual to bear; therefore, common-property regimes are devised to share the risk and spread the burden. The productivity of arid and semi-arid lands is both marginal and variable, and therefore these areas have a benefit-cost ratio that discourages investment in exclusionary, private, mechanisms” (Dyson-Hudson & Smith, 1978; Bromley, 1989; Ostrom, 1990; Behnke, *et al.*, 1993 all In: Niamir-Fuller, 2000 In: McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

Traditionally, pasture was managed as a “Common Property Resource”. Pastoralists varied herd composition depending on the type of long-term environmental adaptation required, drought and markets (see Chapter 2 for detailed discussions). Adams (2003 In: Adams & Mulligan, 2003) believes that this traditional knowledge over range management still exists. “Agropastoral societies have developed their own strategies for reducing their exposure to losses from droughts and for coping when droughts occur” (Hazell, 2000 In: McCarthy, *et al.*, 2000). These strategies include (Hazell, 2000 In: McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute):

- “Diversifying into crops and livestock, particularly around settlement areas, and diversifying into different animal species (for example, goats, sheep, cattle, donkeys, and camels) and different breeds.
- Carrying extra animals that can be liquidated easily during a drought, for either food or cash.
- Adopting mobile or transhumant grazing practices that reduce the risk of having insufficient forage in any one location.

- Adopting opportunistic grazing practices whereby herd sizes and stocking rates are adjusted as the rainy season unfolds to best match available grazing resources.
- Maintaining reciprocal grazing arrangements with more distant communities for use in drought years.
- Maintaining feed reserves or purchasing supplementary feed, such as hay or concentrate.
- Investing in wells and cisterns.
- Diversifying into non-agriculture, particularly seasonal migration and non-farm employment.

Traditional risk-management strategies have proved effective in managing drought risk and have enabled pastoral societies to survive harsh environments for many millennia. The interplay between drought and traditional management systems also helped keep total herd sizes in equilibrium with the inherent productivity of the pastures, avoiding any long-term degradation of grazing areas. Stocking rates would trend upward between droughts, as herders bred more animals, but then would be knocked down again when the next drought occurred. Fluctuations in herd size closely followed rainfall patterns, and peak stocking rates rarely reached unsustainable levels”.

“The literature on western common-property regimes usually assumes that clearly defined boundaries are a necessary condition for long-enduring institutions of common-property regimes” (e.g., Ostrom 1993 *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000). “Pastoral territorial boundaries today are still characterized by the flexibility of their boundaries” (Moorehead, 1993; Salzman, 1994 both *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute) and access to resources that must be negotiated.

“The inclusive (or porous) nature of transhumant tenure institutions has often been misread as evidence for the lack of institutions governing resource access—for example, a resource open to all. Such conclusions confuse a lack of rigid exclusion (a defined membership) with the lack of exclusionary powers. In fact, outsiders can only use resources with the permission of the group with usufruct rights” (Tubiana & Tubiana 1977; El-Arifi 1979 both *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

For instance, in the Sahel, during the rainy season, Tuareg and Fulani pastoralists traditionally moved animals away from the cultivated zone or floodplains into the drier areas of the semi-arid and arid zones to take advantage of the flush of high quality forage produced by grasses on rangelands and to prevent damage to food crops. At this time, livestock made use of water available from surface ponds. During the dry season, livestock was moved back to the cultivated zone to graze crop residues on harvested fields and/or to natural pasturage on the floodplains (Chapter 2, Section 2.3.2, Pasture and Water). As the dry season progressed further, the vegetation on fallow fields was used as temporary pasture (DeGeorges, 1992; Williams, 1998). Access to dry season grazing land on farmers' fields was negotiated.

"Local-resource scarcity has always been a major constraint to pastoral production in dryland areas and has been the major driving force for development of access options based on institutional and market relations. Pastoral communities have always been aware that their local grazing resources will not suffice for more than three to four months and that they need to secure feed for their herds for the remaining eight to nine months. As such, pastoral communities have developed production strategies based on 'free grazing' obtained mainly through reciprocal grazing arrangements, which act as risk-coping strategies" (Ngaido, 2000 *In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

In Niger, the south–north–south transhumance routes depend on rainfall, with herders from Nigeria coming to graze in the pastoral zone of Niger in the rainy seasons. A reciprocal arrangement exists for the dry season, when herders from Niger graze in the pastoral zone of Nigeria. In recent years, however, socio-economic and environmental changes and increasing demands over pastoral land resources have affected the possibility of pastoral institutions solely relying on such arrangements and ensuring the livelihood of their members. Pastures and pastoral resources are increasingly being appropriated by individual members or

encroached on by herders and farming communities. This is resulting in the loss of local institutions' capacities to provide secure production strategies for their members and is weakening the capacity of communities to enforce resource-management rules and win the support of their members. "This loss of institutional capacity and strength is translated in the rural areas into increasing disputes over common-property resources, increasing environmental degradation, and increasing reliance of pastoralists on the market for the upkeep of their animals" (Ngaido, 2000 *In: McCarthy, et al.*, 2000) (see Chapter 5, See Section 5.11.2, Over-population, Desertification and Instability, Nigeria). To a large degree, this may be related to the human and livestock population explosions of the 20th century and to land/resource tenure issues from centralization policies that have largely disrupted the traditional management regimes of pre-colonial Sub-Saharan Africa (see Section 6.1.4, Impacts of Colonialism and Post-Colonialism on Pastoralism and African Ecology).

The seasonal use of "Common Property Resources" also created opportunities for mutually beneficial exchange relationships between various user groups. The exchanges of grain, crop residue and water owned by farmers for the manure produced by pastoralists' livestock linked crop and livestock production for centuries in the Sahel and served to increase land productivity (Williams, 1998). Similarly, livestock grazing on the floodplains helped recycle nutrients back into the aquatic system with the annual flood, helping to increase fish production in a manner similar to the hippo feeding on both aquatic and terrestrial vegetation. Similar cycles were followed by the Maasai (Adams & McShane, 1992; Mbarnoti, 2003), Tswana herders in the Northwest Province, South Africa (Undisclosed Source, *pers. comm.*), at cattle posts in Botswana (Hitchcock, 2003) and in fact across Sub-Saharan Africa. Colonial and post-colonial governments, for a number of reasons, have failed and/or refused to acknowledge the appropriateness of such relationships requiring mobility and flexibility among

stakeholders as a means of assuring sustainability of both livelihoods and the environment.

“Production of protein/ha of traditional nomadic pastoralists in Mali and Botswana is two- or three-fold higher (and at much lower cost in non-renewable fuel resources) than production from sedentary production systems or ranching under similar climatic conditions in Australia and the USA respectively (Breman & de Wit, 1983; de Ridder & Wagenaar, 1984 both *In: de Haan, et al., 1997*). In addition, arid grazing systems are often multiple-use systems, with wildlife and other plant products being important additional products (*de Haan, et al., 1997*)”.

“Studies in Zimbabwe, Botswana, Uganda, and Mali show that overall returns per hectare (counting all products, not just meat) are higher in mobile pastoral systems than in agro-pastoral or commercial systems (Sandford, 1983; Scoones, 1994 both *In: Niamir-Fuller, 2000 In: McCarthy, et al., 2000*). However, productivity per animal is lower, primarily because of the lack of external supplementation and low veterinary input. Another benefit of mobility is its deliberate use for contributing to pasture sustainability and improvement. The mobility of neighboring pastoral herds is a form of spatial and temporal choreography determined by the nutritional needs of the livestock portfolio, informal rules that determine precedence, degree of concentration and length of grazing (that is, effective grazing pressure), and ‘safe’ distance or dispersion between herds (disease or social relationships) (*Niamir-Fuller, 2000 In: McCarthy, et al., 2000, Excerpted with permission from the International Food Policy Research Institute*)”.

“As an example: risk-management strategies put pastoral communities under different property-rights systems and decision-making spheres. For example, when herders in Niger stay in the pastoral zone, Fulani or Tuareg, tribal leaders facilitate their access to pastoral resources, whereas when they are using grazing corridors and areas in the cropping areas, they rely on village and canton chiefs to give them access (*Ngaido, 2000 In: McCarthy, et al., 2000, Excerpted with permission from the International Food Policy Research Institute*)”.

Perkins (1996) also concludes that traditional cattle posts used by local communities have been shown to be more productive than commercial fenced cattle ranches if all livestock products (milk, meat and draught power) are considered on a per hectare basis. Nor does fenced rotational grazing protect vegetation any better than traditional cattle posts that allowed for some mobility. Unfortunately, through Botswana government support to elites, cattle posts have been usurped from traditional resource users, turning traditional herders into permanent residents around the cattle posts who live on handouts. This has resulted in misuse of the areas (e.g., illegal drilling, increased density of boreholes, over-stocking, depletion of communal grazing reserves by elites prior to moving cattle to their private cattle posts or ranches) (see Section 6.1.4.3, Impacts on pastoralism and range ecology from boreholes and Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana).

Traditional pastoralists manage their herds with different goals in mind than Westerners or Western trained technicians and this must be recognized. Adams (2003 *In: Adams & Mulligan, 2003*) states that a traditional pastoralist, a commercial rancher and a conservationist may manage for different goals. The pastoralist will aim for high numbers of lower weight livestock that serve as capital and a source of blood and milk, a rancher will have lower numbers of larger higher meat yielding cattle to serve the market place and the conservationist will be looking to maintain the “integrity” of the ecosystem. It may therefore be rational for a pastoralist to run a larger biomass/number of livestock than a rancher or conservationist would in terms of wildlife. This is acceptable as long as the habitat is not degraded or grazed beyond its ability to recuperate. The carrying capacity in numbers of livestock or game varies with the range resources, which in turn will tend to vary with the climatic cycles of Africa (Adams, 2003 *In: Adams & Mulligan, 2003*).

The harmony and balance, in which nomadic pastoralists had co-existed with nature for millennia, was destroyed in less than a 100 years, mostly during the 20th century (GEF, 1998).

6.1.4 Impacts of Colonialism and Post-Colonialism on Pastoralism and African Ecology

The six major factors influencing African savanna ecology and pastoralism are:

- Centralization of control over-grazing rights.
- Compression from appropriation of land for both European settlers and the creation of parks and protected areas.
- Boreholes.
- Sedentarization policies.
- Human and livestock population increases.
- Loss of floodplain habitat from modified downstream hydrology by dams and from attempted conversion to irrigated perimeters.

6.1.4.1 Impacts on pastoralism and range ecology from centralization of control over-grazing rights

As discussed in Chapter 2, access to pasture, like many resources, tended to be controlled by a lineage within a specified territory. Centralization of control over resources associated with colonialism turned managed “Common Property Resources” into unmanaged “Open Access Resources”.

Throughout Sub-Saharan Africa, the colonial state focused its land policy on crop-production systems, with the pastoral sector being left comparatively untouched and neglected. The current resource tenure structures in Sub-Saharan countries are still based on colonial philosophies. “Existing unwritten customary

rights became subject to and intertwined with written land legislation, causing and accelerating a general insecurity of tenure...particularly for those groups that repeatedly had to prove their customary and secondary right..." Despite differing legal systems in the "mother countries", the effects of French colonial land policy were very similar to those of British colonial land policy (Bassett, 1993; Kirk, 1999 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000). In legal terms, cultivated/occupied land differed fundamentally from "obviously free", unoccupied areas (Feder & Noronha, 1987 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000).

Private ownership rights existed for cultivated land, while uncultivated land, such as pastures, was considered "land without master" (*sans maître*) or "abandoned land" (*terres vacantes*) due to the French's misunderstanding of the spatial requirements of extensive production systems. Uncultivated land could be released for settlement, be transformed into plantations or be converted into areas for mechanized farming (Kirk, 1994; Le Roy, 1985 both *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000).

"The colonial state could also take possession of the land as state land 'in the public interest' without consulting or compensating former holders of rights to the land...As the centralist colonial state did not appreciate the economic importance that mobility has for livestock production in arid and semi-arid areas...the conceptual problem that common-property regimes were mistakenly seen to be systems of open access was the root cause for colonial policies concentrating primarily on the avoidance of what is now called the 'tragedy of the commons' and its negative impact on resource allocation, management efficiency, and sustainability" (Lane & Moorehead, 1995 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

"Under the conquest principle, colonial domination was compared with the conquest of a country: land that was property of chiefs or kings accrues to the French state as a result of conquest or

contracts and becomes part of eminent domain (*domaine éminent*). This approach was, in fact, based on a wrong assessment of the position of the chiefs, who in fact only exercised the function of trusteeship. The principle of abandoned land is based on the French Code Civil and says that the state exercises control over such land as part of the state's *domaine privé* (Coulibaly, Keita, Cissé, Traoré & Soumaré, 1991 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute)".

"In fact, since 1935, all land that had not been used (farmed) for more than 10 years became state land" (Kirk 1999 *In:* McCarthy, *et al.*, 2000) in Francophone Africa. "Thus, resource tenure regulations were put into effect that ignored the logic of opportunistic mobile pastoral livestock keeping and substantiated legal insecurity when, for example, agropastoralists suddenly had to prove their rights to rangeland that had been used temporarily only" (McCarthy, *et al.*, 2000). "The consequences were disastrous for the African population..." (Noronha, 1990 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

Independence tended to be a continuation of colonialism.

"After independence, many African countries continued to work with the institutional environment inherited from the colonial powers without major modifications...policy makers and administrators (often an urban elite who never had and/or who had lost contact with their origins, de-linking themselves from their rural roots, and who had been trained in Western production systems that are often inappropriate for Africa's savannas) identified indigenous pastoral common property and pastoralists' resource management as inadequate for promoting higher levels of commercial offtake, for limiting stock numbers to the carrying capacity, and for protecting the land from being overused" (Lane & Moorehead, 1995 *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

As in colonial times, due to a lack of understanding for traditional pastoral management systems and tenure,

"the implicit theoretical justification was the social dilemma created by common property, which became well known as the 'tragedy of the commons'...The large majority of countries adopted the colonial principle of state ownership of all land that was either without formal title or constituted 'abandoned land'" (CILSS, 1988; Coulibaly, *et al.*, 1991; Lane & Moorehead 1995; Lawry 1989 all *In:* Kirk, 2000 *In:* McCarthy, *et al.*, 2000). "In remarkable continuity with colonial ideals, the state showed an ongoing interest in enforcing state ownership over land communally used until then. Definitely, more land was transformed into state land than into private property" (Lawry, 1989 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

The nationalization of arid rangelands introduced by many governments in the post-colonial period in Africa and Asia (IFAD, 1995 *In:* de Haan, *et al.*, 1997) undermined the intricate fabric of customary practice. An ecologically well-balanced system of communal land use degenerated into a "free for all" "open access" system in much of Sub-Saharan Africa and India (de Haan, *et al.*, 1997; Steinfeld, de Haan & Blackburn, 1997 all *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000) that "undermined the intricate fabric of customary practice" (Steinfeld, *et al.*, 1997 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000). Moorehead (1994 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute) points out,

"Ironically, nationalization of rangelands has created the very conditions that policy was intended to avoid: ranges are now accessible to people who never had such rights before and who are often not pastoralists, in conditions where there is much less control than former communal ownership systems exercised".

In other cases, traditional management areas were

"replaced by individual farms, such as in Algeria, Botswana and Zimbabwe. Individual farms were too small to permit an efficient use of the erratic rainfall patterns inherent in these areas. In

communal areas, the traditional collective internal discipline in the management of the resources disappeared and over-grazing and land degradation followed" (de Haan, *et al.*, 1997).

Perkins (1996) raises similar issues over fenced ranches in Botswana.

"Government policies since colonial times have favored crops over livestock. High import duties aimed at protecting domestic cereal prices, and subsidies on fertilizers and fuel (acting as an indirect subsidy on tractors), have stimulated the expansion of crops into rangelands" (Little, Horowitz & Nyerges, 1987; Lane, 1991; Niamir, Lugando & Kundy, 1994; Steinfeld, *et al.* 1997 all *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

The more productive pastures are the first to go (Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000). In addition, continuing after independence, the

"colonial state's agricultural policies that tolerated or even supported a creeping expansion of crop cultivation into pastoralists' grazing grounds—and was intensified by the installation of large-scale irrigation perimeters in Mali, Sudan, or Senegal—had a far-reaching indirect impact on property-rights regimes of pastoralists", while the introduction of veterinary services resulted in the build-up of herds" (Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

This is exasperated by the human population explosion of the 20th century, declining fallow periods and the movement of farmers onto marginal lands, often key pastoral areas of transhumants. These policies have upset the economic balance that existed between crops and livestock (Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000) (see Chapter 5, Section 5.5.2.2, Nutrient depletion as a constraint to agricultural production; Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal; Section 5.7.1.3, Improperly planned land tenure and

impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya; Section 5.9.1, Over-population, Land Scarcity and Decreasing Agricultural Production in Sub-Saharan Africa; Section 5.9.3.1, The Sahel, over-population and declining fallow periods and Section 5.11, CONFLICT LINKED TO OVER-POPULATION AND DESERTIFICATION – SCARCE RESOURCES).

Large-scale irrigation schemes tended to take place on floodplains that displaced herders and small-scale farmers and tended to require dams that greatly modified the annual flood cycle that for eons had supported a diverse array of resources. These had included dry season forage, necessary for the survival of this ecosystem and the people, livestock, fish, wildlife, water birds and vegetation integrally linked to the floodplains and floods (see Chapter 7).

“In Senegal, Nigeria, or Sudan, large-scale irrigation systems went hand in hand with the expropriation of autochthonous, jointly administered pasture land and its nationalization, which was followed by the allocation of usage rights over irrigated areas to settlers in the form of formal leasehold” (Kirk, 1994 *In: McCarthy, et al.*, 1997). “Again, livestock corridors were obstructed, water points for animals were converted into sources for irrigation, and exchange relations based on reciprocal property rights between agriculturalists and pastoralists were reallocated in favor of agriculturalists” (Kirk, 2000 *In: McCarthy, et al.*, 1997, Excerpted with permission from the International Food Policy Research Institute).

The exclusion of livestock from traditional dry season grazing areas is discussed in more detail in the case study of irrigation and dams on the Senegal River in Chapter 7 (Section 7.9.3.1, Senegal River) that nearly sparked a war between Senegal and Mauritania.

On the Borana Plateau of southern Ethiopia, traditional pastoralists are rapidly losing their land to peasant farmers.

“Until the socialist revolution of 1974, rulemaking and rule enforcing was the sole preserve of the traditional Borana elders. These elders were resistant to the spread of cultivation and to the privatization of land rights. Thus, even though cultivation started in about 5% of the communities some 40 years ago, it never really took off until the formation of the peasant associations in 1975....Across the 40 communities, an average of 22% of the land is privatized, of which 17% is enclosed cultivated fields and 5% is private calf-enclosures. About 80% of the communities in the sample had some cultivation in the 1997/98 agricultural year. Forty-two percent (42%) of the communities had some cultivation 10 years ago, 28% had some cultivation 20 years ago, and 10% had some cultivation 30 years ago...Peasant associations are local administrative units that are supported by the national government. Peasant associations in Borana follow laws promulgated at the national and regional levels that support the allocation of private use-rights to households wishing to cultivate. In at least one instance, a single peasant association was recently given jurisdiction over two *ardas*¹⁰⁹ and individuals from each *arda* rushed to claim rights to individual plots of land. Increases in cultivation were also stimulated by the national government’s special support program for cultivation. Improved seeds, fertilizer, and extension assistance were made available in the 1980s” (Swallow & Kamara, 2000 *In: McCarthy, et al*, 2000, Excerpted with permission from the International Food Policy Research Institute).

In Mali, nationalization of resources by the colonial authorities and the post-colonial governments provided all Malians equal use rights to these resources. However, over time, the complex rules governing access began to unravel, eventually leading to over-exploitation of pasture and other resources (DeGeorges, 1992; Williams, 1998). This included a breakdown of the integrate management system for pasturage and other resources in the Inner Niger Delta

¹⁰⁹ Subdivision of land set aside for pasture, see Chapter 2, Section 2.3.2, Pasture and Water, for a description.

(Williams, 1998; Hesseling, 1994 both *In: Kirk, 2000 In: McCarthy, et al., 2000*), as described in Chapter 2. This phenomenon has been common across the continent, where the colonial powers and present-day governments own the land and the resources, as well as most of the derived wealth. This gives little incentive for local communities to sustainably manage anything. In fact, as the local communities feel the loss of control over pasture and other resources, it encourages mining the resources for short-term gains – creating an “open access” environment.

6.1.4.2 Land compression from expropriation of land for both European settlers and the creation of parks and protected areas

This was discussed extensively in Chapter 3 and has mainly been a phenomenon of settler colonies in East and Southern Africa. Europe’s idea of “Wild Africa” was created by the establishment of parks such as Amboseli and Maasai Mara in Kenya, and Serengeti, Ngorongoro, Manyara and Tarangire in Tanzania. These parks and game reserves were formed by displacing indigenous people and compressing them into smaller and smaller areas. These protected areas had traditionally served as critical dry season grazing areas for local inhabitants’ livestock. The formation of parks combined with expropriation of land by white settlers has greatly reduced the livestock carrying capacity for traditional pastoralists, while impacting on their traditional migratory movements between wet and dry season ranges.

The Orma population, standing at 40,000, currently occupies an area to the west of the Tana River, Kenya, which has an average annual rainfall of 400 to 600 mm spread over two rainy seasons (Jaetzold & Schmidt, 1983 *In: Swallow & Kamara, 2000 In: McCarthy, et al, 2000*).

“Until the middle of this century, the Orma had abundant grazing resources that were governed by a loosely defined set of norms. These resources became increasingly scarce as the Kenyan government expropriated large tracts of land to establish irrigation schemes, game reserves, and government ranches in the 1950s (Swallow & Kamara, 2000 *In: McCarthy, et al, 2000, Excerpted with permission from the International Food Policy Research Institute*”,

as well as due to encroachment by Turkana herders because of drought. As a result:

“the Orma devised a system of restrictions on the use of pastures near their villages. This effectively excluded transhumant herds and established a local commons. The Orma Council of Elders oversaw the management and use of the common pastures. This Council was a decentralized form of government that relied on consensus of community members. Individual community members enforced the decisions of the Council” (Swallow & Kamara, 2000 *In: McCarthy, et al, 2000, Excerpted with permission from the International Food Policy Research Institute*).

Displacement of Khoikhoi pastoralists by Dutch settlers began in 1652, converting their lands to fenced farms for crops and continual grazing. This disrupted their traditional production systems through bringing them into a barter system, exchanging livestock for trade goods, including alcohol. These developments, together with the elimination of internecine wars and the eruption of the small pox epidemic of 1713, which killed up to 30% of the population, resulted in the Peninsula Khoi of the Western Cape South Africa, no longer being self-sufficient: they became unviable both socially and economically. Following a skirmish in 1659, a captured Khoikhoi responding to a question about why they were at war with the Dutch asked why the Dutch had ploughed and sowed corn on their best pasture lands (Smith, 1992). The Khoikhoi were eventually forced to work as hired hands or pushed into urban centers by the beginning of the 18th century.

The idea of depicting Africa's savannas as wilderness untouched by human hands is fundamentally flawed (Adams, 2003 *In: Adams & Mulligan, 2003*). In fact, humans have played a key role in the maintenance of savannas through the burning and harvesting of woody species for charcoal and firewood. In large parts of the subcontinent, humans overplayed their role, which led to desertification and was compounded by the human and livestock explosion in the 20th century and colonial/post-colonial policies. The process of land confiscation and compression, especially in the creation of parks and protected areas, continues in the 21st century, as is discussed in Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers. This process is taking place through the investment of Western money and is driven by Western "ecological missionaries", mostly NGOs, who collude with African government elites and the private sector (e.g., tour and safari operators, logging companies, etc.). The NGOs act for ideological reasons in the name of biodiversity conservation, governments as a way of enriching the elite, and the latter as a cover to plunder Africa's real wealth – its natural resources while the majority of rural Africans remain poor, uneducated and are pushed into geographically limited areas that cannot support them ecologically or economically.

6.1.4.3 Impacts on pastoralism and range ecology from boreholes

What cash crops have done to Sahelian farmland, deep borehole wells have done to savanna pastures. A thousand feet or more beneath the Sahel lay vast reservoirs of water that could be tapped by deep wells. The effect of the boreholes was simply to make pasture instead of water the limiting factor on cattle numbers, so that the inevitable population collapse, when it came, was all the more ferocious (Hardin, 1977). This has been true across Sub-Saharan Africa.

Beginning in the colonial era of the 20th century, in the dry rangelands of the Sahel from Senegal to Chad, “Western rangeland experts” determined that the limiting factor to increasing livestock carrying capacity was water. Across the Sahel, boreholes were constructed. Perennial boreholes replaced traditional temporary shallow watering holes, encouraging sedentarization. Concomitantly, as human populations increased and fallow periods began disappearing, farming expanded further and further into rangelands. Extensive pastoralists, who moved between wet and dry season grazing areas, were placed into an intensive management situation for which they were ill-prepared, both culturally and technically (Princeton University, 1986). Continuing into the 21st century, across arid Africa, countries have subsidized (often with foreign aid money) the drilling of boreholes, creating 1000s of mini oases. Peasants and nomads flock to these boreholes to take advantage of the “free” (unowned and unpriced) water and land. This allows livestock numbers to build up, encourages sedentarization, results in habitat degradation and displaces wildlife.

Between 1947 and 1961, France spent over 50,000 old francs on the Sahelian area of Mauritania, Senegal, Mali, Niger and Chad, providing boreholes and artificial or controlled natural ponds for cattle herds. All these areas became over-grazed (Dumont, 1966; Dumont, 1968 *In: de Vos, 1975*). Great Britain did the same to appease the Maasai for the land they had confiscated for settlers and to create parks and reserves (Adams & McShane, 1992).

“The provision of 1000s of ‘public’ wells and boreholes in dryland areas after independence further contributed to the destruction of the autonomous, efficient allocation of scarce water resources. The new public facilities offered all groups increased access to new pasture grounds, and access by foreign herders became uncontrollable for the local groups. In Mauritania and in Sudan, this process of undermining locally based property rights was aggravated by applying Islamic resource laws, which provided

much broader access to water and grazing resources than many customary systems did" (Lane & Moorehead, 1995; Kirk, 1994 both *In: McCarthy, et al.*, 1997, Excerpted with permission from the International Food Policy Research Institute).

In the Sahel, the installation of boreholes was undertaken with little or no understanding for the impacts on traditional management systems or pasture quality. Culturally, livestock, as opposed to money, were seen as wealth. Thus, few if any livestock were taken off the range. With the year-round availability of water and improved veterinary care, herd sizes were increased, adding to the pressure on the range.

Livestock cannot walk more than 15-20 km/day between grazing areas and water while maintaining their condition. Linked to this, boreholes must be carefully managed (opened or closed) in order to control grazing pressure (de Vos, 1975). This is something that was rarely addressed by donors and developers after they had dropped this technology on local pastoralists. As migratory Sahelian herders were untrained in intensive grazing practices, they became sedentary around boreholes in rainy season grazing areas, because of the availability of year-round water supplies, rather than opening and closing boreholes and moving livestock as range was grazed down. Each day, livestock migrated out from the boreholes to feed, until 20 km circles of degraded rangeland were created (Princeton University, 1986).

In the Sahel of Africa, traditionally,

"heavy grazing during the dry season resulted in areas of denudation up to about 30 km from a well, but wells were spaced at large intervals so most of the land was ungrazed. With bores (boreholes) now at less than 30 km intervals most of the land area is denuded by the end of the dry season" (Glantz 1977 *In: Landsberg, James, Morton, Hobbs, Stol, Drew & Tongway, 1997*).

Le Houerou (1979 *In: Smith*, 1992) states that

“putting high yielding boreholes into operation to water cattle allows enormous concentrations of herds during the dry season. In the Sahel and particularly in Niger, it has been known for boreholes to water 40,000 to 50,000 head. Because the animals cannot go more than 20 km from water sources during the hot dry season, in a very few years the pasture is entirely destroyed”.

It is estimated that between 1957 and 1968, 1,000 boreholes were installed in Sudan, which led to the stripping of 200,000 km² of its grass cover (Rosenblum & Williamson, 1990). Rapp (1976 *In: Landsberg, et al.*, 1997) reports that “cattle grazing around artificial water in northern Sudan has resulted in the denudation of vegetation and soil compaction over areas of up to 100 km diameter” (Landsberg, *et al.*, 1997). Where boreholes were close enough together and the concentric circles connected, deserts were formed. If one flies across the Sahel today, these interconnected circles of desertification become obvious (Princeton University, 1986). This continued during the drought of the 1960s/70s (Williams, 1998) and into the present with support from:

- Western donors in Niger (Salopek, 2001) and Namibia (Devereux, Rimmer, LeBeau & Pendleton, 1993 *In: Devereux*, 2001 *In: Devereux & Maxwell*, 2001);
- Missionaries in Maasailand, Tanzania (principal author personal observations); and
- Governments, Botswana (Hitchcock, 2003) and individuals (Hitchcock, 2003).

In the Sahel, foreign aid programs brought in more wells and boreholes, which increased concentrations of people and animals. Extensive animal health campaigns resulted in vastly increased numbers of stock. The desertification

process was started (van Voorthuizen, 1978). These actions were often taken in an attempt to slow the movement of pastoralists southward during the drought of the 1970s, as a means of stopping them from encroaching on small-scale farmers. In the end, this only worsened the impacts of the drought and often resulted in ethnic conflicts (Martin & O'Meara, 1995). For example, the Illabakan Tuareg of Nord Tahoua, Niger initially responded favorably to deep boreholes until other Tuareg groups and Fulani started basing themselves around the borehole at In Waggeur, heavily over-grazing the pasture. In reaction, the Illabakan Tuareg requested that the pump be turned off (Bernus, 1974 *In:* Smith, 1992).

In Botswana, deep boreholes dating back to colonial times in the 1930s opened up vast areas of the country previously unavailable to livestock except during the rainy season. Permanent access to grazing lands increased from 20% in 1936 to 45% in 1986, while the cattle herd increased from 1.2 million in 1934 to 3 million by 1998.

“Since the boreholes were mostly owned by individuals or syndicates, the grazing around them began to be seen as belonging to the borehole owners, thus laying the seeds for the privatization of communal grazing land in the years to come” (Cullis & Watson, 2005).

In Botswana, the de facto privatization of water sources and rangelands, through the Tribal Grazing and Land Policy of 1975, was aimed at the commercialization of extensive livestock keeping through private ranches. This was based on the conviction that fenced ranching is more productive than communal rangeland development (Bruce, Freudenberger & Ngaido, 1995; Lane & Moorehead, 1995; Le Roy, Karsenty & Bertrand, 1996 all *In:* McCarthy, *et al.*, 1997). Boreholes close to cattle posts have reduced the seasonal movement to traditional rainy season grazing areas, with the result that there is severe local over-grazing and degradation close to population centers. Privately dug wells and boreholes upset

Tswana traditions where water was to be made freely available to whoever needed it, allowing private ownership of the water and de facto ownership of the grazing land around the water supply (Hitchcock, 2003). Boreholes mainly went to wealthy livestock keepers, the associated pastures being regarded as private land.

“The largest part of the remaining area stayed communal land. The distributive consequences of planned fencing should have been predictable: the establishment of private property for more wealthy borehole and livestock owners, and the deprivation of the poorer segment and a neglect of minority rights” (Kirk, 2000 *In: McCarthy, et al.*, 1997, Excerpted with permission from the International Food Policy Research Institute) (see Chapter 3, Section 3.4.2.3, The legal exclusion of the African hunter from his wildlife, Loss Of Hunting And Territorial Rights By “San” Bushmen, Botswana).

Drilling of public boreholes in drier areas of rural Botswana (e.g., the Kalahari) facilitated expansion in the number of livestock that could be kept year-round in what had been rainy season grazing areas. The rising numbers of livestock and the reduction of their mobility contributed to a process of over-grazing and environmental degradation. Consequently, both chiefs and the Protectorate administration began to call for the privatization of land in order to counteract what they saw as problems of communal land and water access. A major problem in the livestock sector of Botswana is that although land use planning efforts are expanding both in number and sophistication, the ad hoc drilling of boreholes continues without any real controls being implemented to ensure better range management. Efforts are now being made to coordinate activities between the Department of Water Affairs, the Department of Geological Survey and the Water Utilities Corporation (Hitchcock, 2003).

In attempting to quantify the impacts of cattle around boreholes in the Kalahari¹¹⁰, Perkins and Thomas (1993) and Perkins (1996) describe the zonation of the piosphere with distance from the borehole as:

- 0-50 meters, considerable nutrient enrichment from Extreme Herbivore Use Intensity (HUI).
- 0-400 meters, Sacrifice Zone, vegetation destroyed, surface disruption by wind erosion.
- 200-800 meters, Nutritious Grass Zone, negligible soil changes, dominance of palatable nutritious grasses.
- 200-2,000 meters, Bush Encroachment Zone.
- >2,000 meters, Grazing Reserve of climax unpalatable tufted perennial grasses.

Thus, Perkins and Thomas (1993) and Perkins (1996) state that in the Kalahari, impacts on the natural environment do not exceed a 2 km radius from the borehole. Bush encroachment is believed to occur in over-grazed areas from reduced competition by grasses, increasing the availability of water to woody species. Species such as *Acacia spp.* are favored because of their shallow roots that are able to pick up irregular and sporadic rain that wets only the surface soil. In addition, in the nutrient poor savanna soils, *Rhizobium spp.* bacteria are able to form symbiotic nodules on the roots of the *Acacia* that can fix atmospheric nitrogen, making it available for use by the *Acacia* (Skarpe, 1990). Perkins (1996) explains that the bush encroached zone can probably revert back to open savanna via fire effects in the long-term. However, the bush encroached zone can also expand outward with time, depending on stocking rates and borehole density (Perkins & Thomas, 1993). Perkins (1996) and Perkins and Thomas (1993) argue

¹¹⁰ 75% of Botswana is occupied by the Kalahari Desert sandveld with about 400-500 mm of rainfall/year (Perkins & Thomas, 1993), whereas the Sahel ranges between 200-400 mm of rainfall/year (see Chapter 1, Figure 1.3).

that the browse from bush encroachment serves as food for goats during normal times and as a food reserve for cattle during drought periods, helps prevent wind erosion and in its shade provides a seed bank of grasses along with the grazing reserve to recolonize the area once rains return. Periodic droughts, heat stress and physiological limitations result in cattle being unable to graze extensively in the unpalatable grazing reserve and make it impossible to maintain high stocking rates on drought-depleted rangelands for long-periods of time. This helps to maintain the integrity of the grazing reserve. Thus, water from boreholes during the dry season/droughts and rainfall during normal times remain the key limiting factors controlling grazing availability and livestock production (Perkins & Thomas, 1993; Perkins, 1996). This seems to contradict observations by Rosenblum and Williamson (1990) around boreholes in the Kalahari of Botswana, where it is claimed that one borehole can destroy a circular piosphere of 777 km² (300 square miles), a radius of about 15.7 kilometers, resulting in human-made desertification. There really is no contradiction, with rainfall and humans, as is discussed below, being the determining factors as to the ecological response to over-grazing. The density of boreholes that may eliminate rainy season grazing reserves by connecting piospheres may be one of the major culprits in range degradation.

For comparison, in Australia, it is estimated that cattle can walk 20 km a day, but most grazing occurs within a 10 km radius of the piosphere. Sheep that dominate southern rangelands may walk up to 10 km a day, but the majority of the grazing is within 5 km of the piosphere (Landsberg, *et al.*, 1997). In southern rangelands under hot conditions, foraging by sheep may be reduced to 3 km (James, Landsberg & Morton, 1999). Half of the grazing pressure in the southern rangelands of Australia (northern New South Wales and southern Queensland) comes from kangaroos and goats that may walk a minimum of 20 km/day. The main feral animals of northern Australia, horses, donkeys and camels, can walk at

least 20 km/day (Landsberg, *et al.*, 1997). Camels can go for periods of four days in summer to 89 days in winter without drinking (James, *et al.*, 1999). Thus, 10 km is considered an average piosphere well within the range of these animals (Landsberg, *et al.*, 1997). Zonation similar to the Kalahari studies was observed; shrub cover was low in the sacrifice zone within 400 m of the water point, increased rapidly around 1 km and reached a stable maximum percentage cover 2–3 km from water.

“Within 2 km of artificial water some generalizations are apparent. When heavy grazing removes competition from palatable species, or those sensitive to trampling damage, ‘increaser’ species¹¹¹ establish. These are typically species with ‘annual’ life histories that flourish after rain, or unpalatable perennial shrubs” (Landsberg, *et al.*, 1997).

“There is also evidence that in some areas under-grazing of remote pastures, as a result of sedentarization, is a more serious problem than over-grazing” (Galaty, 1988; Warren & Rajasekaran, 1993 both *In: Niamir-Fuller, 2000 In: McCarthy, et al, 2000, Excerpted with permission from the International Food Policy Research Institute*).

“For example, piosphere (vegetal zones related to watering points) studies around agropastoral villages in northeastern Senegal show that undergrazing of distant pastures results in lower palatability of primary productivity, lower phosphorus content of topsoil, lower herbaceous density, and lower biomass production” (Niamir, 1987 *In: Niamir-Fuller, 2000 In: McCarthy, et al, 2000, Excerpted with permission from the International Food Policy Research Institute*).

“Thus the new range ecology postulates that, for grazing to have little or no negative impact on arid rangelands, it must follow or ‘track’ climatic variability” (Niamir-Fuller, 2000 *In: McCarthy, et al, 2000, Excerpted with permission from*

¹¹¹ “Increaser” species are indicators of over-grazing and take over as the dominant species from more palatable “decreaser” species that are selectively preferred by grazers and reduced/eliminated (see Section 6.1.4.5, Impacts of boreholes, over-grazing and over-use of fire on palatable grasses).

the International Food Policy Research Institute), that is imitate traditional wet/dry season transhumance movement of livestock that maximizes utilization of rangelands on the subcontinent.

The placement of boreholes and watering points in rainy season grazing areas continued into the mid-1980s, even in Heuning Vlei, Northwest Province of sophisticated South Africa (Undisclosed Source, *pers. comm.*), with good intentions, but in complete ignorance about the likely outcome: over-grazing, bush encroachment and trampling. Likewise, in Namibia, during the 1992-93 drought, the government drilled 100s of boreholes and provided fodder to protect herders' assets (livestock) even though ecologists were concerned that these artificially preserved large herds would cause accelerated degradation around water points (Moorehead & Wolmer, 2001 *In:* Devereux & Maxwell, 2001).

With regards to wildlife, Senzota and Mtahko (1990) state that in the Mikumi National Park, Tanzania, the impacts of browsers on grass cover were significant only within 100 meters of a dam, with 80% of the zebra and 90% of the wildebeest spending less than three minutes there, most likely because waterholes tend to be sites of predation.

Why the variation in observations as to the impacts from boreholes on vegetation?
There are a number of possible explanations:

Rainfall

Jeltsch, Milton, Dean and van Rooyen (1997) argue that the classic piosphere description as given for the Kalahari and Australia did not occur in low rainfall events, with the increase in shrub cover (bush encroachment) being limited. This lack of bush encroachment has been noted by Hanan, *et al.* (1991 *In:* Jeltsch, *et*

al., 1997) in the Sahel and van Rooyen, Bredenkamp, Theron, Bothma and le Riche (1994 *In:* Jeltsch, *et al.*, 1997) in the Kalahari Gemsbok National Park. Jeltsch, *et al.* (1997) state that under a higher rainfall scenario, regardless of stocking rate, the classically described piosphere developed with bush encroachment. Jeltsch, *et al.* (1997) have found highly resilient shrub encroachment in higher rainfall areas in piosphere zones with virtually no recovery over a 100 year period, which was modeled. It is assumed that this is without humans in the equation (see Section 6.1.4.4, Bush encroachment versus desertification). Under the low rainfall scenario, the higher formation of bare soil causes soil erosion, which eventually is more permanent and less reversible than shrub encroachment (Jeltsch, *et al.*, 1997). In South Africa, Ward (2005) also found that “rainfall amount and frequency, coupled with specific soil nutrient levels, may drive this phenomenon” bush encroachment as much, or more so than over-grazing and fire.

In Southern Australia, and it is assumed that this would hold for the low rainfall areas of Sub-Saharan Africa,

“soils in arid environments worldwide are generally nitrogen and phosphorous deficient, and soils in arid Australia are generally more deficient than those in other countries. Most nitrogen available to plants is held in the top 10 cm of soil as a result of breakdown of organic matter (Charley & Cowling, 1968 *In:* Landesberg, *et al.*, 1997) and nitrogen-fixing algae in cryptogamic crusts (Mayland & MacIntosh, 1966 *In:* Landesberg, *et al.*, 1997), but see Snyder and Wullstein (1973 *In:* Landesberg, *et al.*, 1997) for an alternative view on the role of cryptogamic crusts in providing nitrogen.

Heavy traffic by stock breaks up the cryptogamic crust (Eldridge, 1996 *In:* Landesberg, *et al.*, 1997) which has two consequences: 1) the nitrogen-fixing action of the cryptogams is disrupted; and 2) the soil surface is loosened allowing wind and water erosion to remove surface layers. Charley and Cowling (1968 *In:* Landesberg, *et al.*, 1997) suggested that removal of this vital surface layer

prevented regeneration of degraded chenopod shrublands in southern Australia (Landesberg, *et al.*, 1997)".

This same phenomenon occurring in Sub-Saharan Africa in low rainfall (e.g., under 400 mm/year) areas without the mitigative effects of bush encroachment would ultimately result in desertification such as with the Harmattan winds of the Sahel blowing away the top soils of over-grazed rangelands, resulting in increased desertification with little or reduced vegetational cover of low palatability during the rainy season.

Distance between Boreholes/Borehole Density

A major factor impacting vegetation is the distance between watering points. In Western Australia, the average distance between boreholes/water was 7 km and 11.2 km for sheep and cattle lands, respectively. The average spacing of water points in mulga (*Acacia aneura*) woodland habitats of northern New South Wales and eastern South Australia was 5.5 km on sheep properties and 11.0 km on cattle properties. In a similar biome in southwest Queensland, the average distance between watering points was 5 km. For cattle in central Australia, mesic periods (moderately moist) when forage is of high quality result in cattle movements of only 4 km from water (Hodder & Low, 1978 *In: James, et al.*, 1999). Under dry conditions, when feed is sparse or of poor quality, movements up to 10 km result (Hodder & Low, 1978 *In: James, et al.*, 1999), and in very poor quality habitat, or during winter, cattle may occasionally move over 20 km from water (James, *et al.*, 1999). Thus, if watering holes are too close, livestock can graze between piospheres, extending the zones of bush encroachment or desertification depending on the rainfall levels.

In the Kruger National Park, South Africa, Thrash, Nel, Theron and Bothma (1991a; 1991b *In: James, et al.*, 1999) and Thrash (1998 *In: James, et al.*, 1999)

state that while the measurable effects of grazing around artificial water points were only evident for a few kilometers, there was loss of habitat diversity at greater distances due to the increased density of water points, hence the increase in the amount of area that is available to grazing animals during the dry season. Thus, if piospheres overlap, the potential exists to have massive areas of degradation. As already noted above, overlapping piospheres from too closely placed boreholes can result in massive degradation (Section 6.1.4.3, Impacts on pastoralism and range ecology from boreholes).

Harvest of Bush for Firewood and Charcoal

Humans co-evolved with the mega-fauna and savannas of Africa and play an important role in their maintenance. The elimination of humans from this equation by a Western-driven conservation movement fails to understand and/or ignores their role in the biome. Seeing humans as the problem rather than part of the solution to the management of savanna ecosystems is a major cause of the problems, which are discussed below in Section 6.1.4.4, Bush encroachment versus desertification.

Fire

Throughout the Sahel and West Africa, the savannas are burned annually. As is discussed below in Section 6.1.4.4, Bush encroachment versus desertification, there is a general tendency in East and Southern Africa not to burn and to even discourage burning. This no-burn policy appears to be a remnant of British colonial policies applying inappropriate Eurocentric temperate climate ecological principles to African savannas. The United States, that had an inappropriate “Smokey The Bear” don’t burn policy in the 1950-1970s, today, with better understanding of ecology, is changing to controlled and even natural burning

(Hess, 1993), especially in the arid and semi-arid West. Similarly, African savanna ecologists are just beginning to understand the functioning of these ecosystems for which humans and fire play a dynamic role in the maintenance of savannas. Fire suppression results in bush encroachment, while in areas with annual burning this will tend to hold back the bush. According to Funston and Brits (*pers. comm.*), the organic load in the Kalahari is too low and burning rarely takes place, so that fire is not part of the equation in this system. Bush encroachment will likely occur in higher rainfall areas with little or no fire and low population densities, while desertification will likely occur in lower rainfall areas.

On the Borana Plateau of southern Ethiopia, “the ban on bush fires imposed by the national government in the 1970s led to a dramatic increase in bush encroachment and subsequent loss of grazing areas” (Swallow & Kamara *In:* McCarthy, *et al.*, 2000).

Concerning the ban on burning in the Ngorongoro Crater, “the ban on burning promoted the observed ecological changes in the Crater’s that favor buffalo over wildebeest and Thomson’s gazelle, black-backed over golden jackals and so on. No other factors considered during the present study appear of equal importance” (Estes, Atwood & Estes, 2006).

Animal Densities

The amount and intensity of grazing will determine the degree of degradation around watering points. Wildlife that co-evolves with humans in African savannas tends to self-regulate, unless artificially stocked like livestock as on Southern African game ranches. A combination of no-burn policies, human and livestock population explosions in the 20th century, and compression from land expropriation for cultivation, parks and protected areas, spacing of boreholes and artificial subsidies, such as those coming from the Lomé Convention, increased

the concentration of livestock across Sub-Saharan Africa. This has resulted in over-utilization and degradation of Africa's savannas, be it bush encroachment and/or desertification.

6.1.4.4 Bush encroachment versus desertification

Why does over-grazing tend to result in desertification in much of West Africa, while in the fenced parks and game ranches of South Africa we see so much bush encroachment? The principal author never observed obvious bush encroachment in West Africa. The bush came back to some degree around fallow fields, though with reduced fallow, there was less and less secondary bush, and on the Ranch du Doli, a cattle ranch in Senegal, where cattle numbers were carefully controlled, and man's involvement was minimized – especially for charcoal and firewood production. In the 1980s, this ranch stood out on satellite and aerial photos on an otherwise barren landscape.

Blankenship, Parker and Qvortrup (1990) note that around Lake Elimenteita, prior to European colonization, "Maasai periodically burned the plains and perhaps kept the bush from further encroachment into the grasslands". In fact, conservationists are just beginning to realize that without the Maasai and their cattle, the Serengeti grassland ecosystem is suffering from bush encroachment (Colchester, 2003). Kjekshus (1977) notes that burning and the woodman's ax pushed back the bush in Tanzania (see Chapter 2, Section 2.1.2, Controlling Wildlife Distribution by Habitat Management) that was reclaimed as the result of a catastrophic series of events in the 1890s, which drastically reduced both human and livestock populations (Chapter 3, Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya) as nature temporarily won out. Along with the return of the bush came the tsetse fly and sleeping sickness (see Chapter 3, Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya).

The British colonial policy in East Africa discouraged burning (Kjekshus, 1977). In Kenya, with the coming of the European settlers, fire was “better controlled” and with the help of grazing from livestock, bush (woody component) became more predominant in much of the area (Blankenship, Parker & Qvortrup 1990).

The first time bush encroachment from over-grazing was pointed out to the principal author was around Lake Mburo National Park, Uganda, where during the dry season up to 80,000 cattle graze within the park (see Chapter 11, Section 11.11.2, Donor driven conservation, Lake Mburo National Park (LMNP), Uganda).

Meanwhile, in the Limpopo and Northern Provinces on game ranches and even in the Kruger National Park, bush encroachment is a major problem. Yet, historical accounts by early explorers and hunters indicate that much of northern South Africa and neighboring Namibia, both suffering major bush encroachment on their farms, were open savanna 100 or more years ago. Even in Kruger, the (what some consider too) many elephants (11,000 in 2004), known for their propensity for creating savanna, cannot seem to hold the bush back. According to Kruger Veterinarian, Roy Bengis (*pers. comm.*), a problem with the idea of elephant holding back the bush is that they are selective feeders and thus cannot serve to completely hold back the bush on their own. It is mainly the bulls that push down the biggest trees (Thomson, 2003; Bengis, *pers. comm.*) and ring-bark trunks, especially bull herds (Thomson, 2003), which results in the death of trees. Once one bull starts breaking down a tree, it stimulates other bulls to do the same. Thomson (2003) believes that this phenomenon is especially true in larger bull herds, where demonstrating strength helps to reinforce position in the hierarchy. Cows and juveniles feed mainly on tree seedlings, the under-story plants in woodlands or on ground plants in open scrublands. Bulls also feed on this vegetation, but spend an inordinate time on larger trees. Thus, there is more

habitat damage by bulls than breeding herds since bulls damage older trees that take longer to replace (Thomson, 2003). However, over-populations of elephants can have major impacts on vegetation, impacting both habitat and biodiversity (see Chapter 3, Section 3.9.1, Eco-Genocide and the Elephant People and Chapter 10, Section 10.4.5, Does CITES Help Southern African Elephant Conservation? and Section 10.4.5.1, Hwange National Park, Zimbabwe) (Figure 6.1). This is especially true where increasing elephant populations, because of human and/or physical fences, cannot easily disperse. Ultimately, whether this is considered positive or negative depends on management objectives.

It appears that two of the major differences between Southern Africa and West Africa may very well have to do with the exclusion of humans from the system with annual fires, chopping down the bush as fodder for livestock that browse once the grasses are consumed, and the intense harvesting of the bush for charcoal and firewood. Fire in West Africa is undertaken for a variety of reasons: 1) *feu précoce*, precautionary fires early in the dry season to protect villages from burning down as a result of uncontrolled wild fires, and which open the village up visually so that predators can be easily observed, 2) burning about two months into the dry season to obtain a second flush of grass for livestock and wildlife, though this often takes place too late into the dry season, resulting in hot fires that kill the growing part of the trees/shrubs the crowns, which results in the death of this vegetation, 3) opening up the bush for better visibility by hunters and 4) tsetse fly control. Some range and pasture management experts argue that if productivity is the main objective, burning at this time is not prudent since it uses up vital nutrients normally stored in the root system of perennial grasses until the next rainy season. It is suggested that burning take place just before or just after the first rains, while the grass is still dormant (Krynauw, *pers. comm.*). Nevertheless, in East Africa where suppression of fires has been encouraged by well meaning but misinformed resource managers,

“the Maasai regularly burn high-rainfall areas in the (Ngorongoro) Crater Highlands, for the stated reasons of controlling tick-borne diseases and providing pasture with a high nutritional value. ‘This strategy would appear to be successful, as the incidence of ticks was very low in the rangelands utilized by domestic livestock outside the Crater. In comparison to extensive areas of the Crater dominated by *Chloris gayana* (Rhodes grass) the grasslands (in Maasai area) were generally not overgrown and moribund’ ” (Trollope & Trollope, 2001 *In: Estes, et al.*, 2006).

Maasai burn just before the first short rains in October (Mbarnoti, *pers. comm.*).¹¹²

The principal author vividly remembers what appeared to be manicured mango trees in villages all over West Africa. Where once grass was consumed, cattle began eating leaves as a means of survival. By cutting down the bush under such conditions, humans can feed their livestock, obtain firewood for their home and obtain cash income from selling charcoal to the cities. West African goats become arboreal during the dry season, spending much of their days in trees feeding on leaves and seedpods that cannot be reached from the ground.

Bell (1971 *In: Smith* 1992) states that both fire and pastoralism permitted the expansion of the grazing conditions from edaphic grasslands into higher rainfall and higher productivity areas where trees originally predominated. In the highlands of Cameroon (e.g., Bamileké Plateau and Adamoua Plateau), grass fields had largely replaced forests 2,000 to 3,000 years ago (1,000 BC to 0 A.D.), one of the reasons for the Bantu migrations (Chapter 1, Section 1.7, BANTU AFRICA) (Vande weghe, 2004). In over-populated Rwanda and Burundi, as farmers cleared forests, farmed and then abandoned this land for freshly cleared land from virgin forests further up the mountain, pastoralists kept forests from

¹¹² Edward L. Mbarnoti, Maasai Elder, Loibor Siret, Simanjiro, Tanzania, 2004 graduate and B-Tech candidate, Dept. of Nature Conservation, Tshwane University of Technology (TUT), Pretoria, South Africa. Currently, alarmalimuli@yahoo.com.

returning by maintaining permanent grassland, where grassland had not naturally existed in the past (Vande weghe, 2004). Likewise, Smith (1992) suggests that as agriculturists cleared the bush, pushing back the tsetse fly, war-like pastoralists may have displaced these agro-pastoralists/agriculturalists, thereby continually pushing the Bantu iron-using people southward through East and Southern Africa (Chapter 1, Section 1.7, BANTU AFRICA), where they eventually arrived at the Fish River, East Cape Province, South Africa. They were, however, stopped from advancing due to having only summer-rainfall crops in a winter- rainfall environment (see Chapter 1, Section, 1.1, PRE-HISTORIC AFRICA – THE CRADLE OF MANKIND).

Thus, humans and livestock help maintain grasslands and develop grasslands or savannas dominated by grasses where they did not traditionally occur. On the other hand, without continued maintenance, much grassland/savanna would revert to closed canopy woodland with concomitant tsetse fly infestation (Smith, 1992), as is discussed in Chapter 2, Section 2.1.2, Controlling Wildlife Distribution by Habitat Management and Chapter 3, Section 3.1.8.1, Ecology of an empire in Tanganyika and Kenya; thus, taking away humans and livestock results in bush encroachment. It also appears, as on South African farms, that over-stocked cattle alone cannot hold back the bush and in fact cause bush encroachment by eliminating the build-up of biomass from over-grazing, which can result in hot burns that kill the bush. The grazing of cattle, in combination with humans and their management of the bush through regular burning and the harvest of the woody component for firewood and charcoal can result in the opposite impact if taken to the extreme, namely desertification, especially in low rainfall areas.

Dr. Paul Funston (*pers. comm.*), a lion researcher at Tshwane University of Technology's (TUT) Department of Nature Conservation, gave a very well received but controversial presentation at a workshop in the Kruger National Park.

He explained that bush encroachment in the northern part of the Kruger National Park, in addition to other factors, which are discussed below, impacted the viability of roan and sable populations among others. He argued that many areas, in which he had been conducting research, were closing up and that unless humans and/or the simulation of human activities were reintegrated back into the management of the park; there would be a major loss of habitat in the future (Figure 6.2).

At the April 2004 Wild-Expo Game Ranching Symposium in Pretoria, South Africa, Jordaan (*pers. comm.*) concluded that bush encroachment on game ranches in South Africa is a major problem, resulting from over-grazing by livestock when many of these farms used to be cattle farms combined with a no burn policy. Today, there is not enough grass in much of South Africa's bush encroached Limpopo and Northern Provinces to sustain viable livestock populations. This is a major reason, in addition to economics, why many ranches are being converted to wildlife, which make more diverse use of the vegetation, including browsing. An additional constraint is that many game ranches are too small to be well managed or economically viable. The average game ranch in the Limpopo Province is about 800 ha (Botha, *pers. comm.*). In many cases, these farms are over-stocked and if a portion of the farm is burned, the resulting new flush of grass is over-utilized by the grazing game, which causes habitat degradation. There is also a reluctance to use fire as a management tool on small farms for fear of the fire spreading to adjacent farms, resulting in a de facto no-burn policy. Also, on small farms used for tourism, burns appear unsightly to the tourists and are thus not favored as a management tool. Jordaan (*pers. comm.*) is concerned that unless fire is reintroduced, in essence recreating both humans and nature, and bush encroachment is controlled on these game ranches, the future for wildlife on many of South Africa's bushveld game ranches may be bleak, as carrying capacity may be significantly reduced.

Thus, the currently experienced problems in management of Southern Africa's savannas may arise in the exclusion of humans in low densities. The historical presence of humans in savannas has had a co-evolutionary effect on the ultimate nature and content of savannas in the pre-conceived "parkland" landscape, viewed as the ideal by current wildlife managers.

In free-ranging, low rainfall, over-populated areas of Southern Africa, one can observe similar conditions to the Sahel. Figures 6.3 and 5.10 were taken by the principal author in the winter (August) of 2003, in Mozambique, along the road from Tete to the Chimoio Highway leading into Zimbabwe (see Chapter 5, Section 5.9.4.7, Deforestation in savanna environments - Deforestation in Senegal linked to charcoal making, over-population and declining fallow periods). This looked just like the Sahel, over-grazed bare ground with open bush. It is obvious that fire, over-grazing and harvesting of the bush have minimized the impacts of bush encroachment observed on South Africa's fenced game ranches and parks. In the foreground of Figure 5.10, charcoal is for sale. Similar to the Sahel, these areas in Mozambique have very low rainfall, which likely contributes to the "behavior of the bush" from overuse by humans. According to de Haan, *et al.* (1997), in the case of the Borana region of southern Ethiopia, but true for much of Sub-Saharan Africa

"the larger number of people in the region means that fuelwood is being cut at an ever greater rate. The inevitable result of all these pressures is land degradation. Drought often exacerbates such situations and, indeed, the ability to recover after drought is one of the main indicators of long-term environmental and social sustainability of arid grazing systems".

Humans are the difference and the future may very well be how to integrate, not exclude, them and their traditional use of Africa's natural resources in a manner that results in a positive benefit to both humans and nature.

Interestingly enough, on the Lord Delemere Estate in Kenya (personal observation in the early 1990s) and on the Kekopey Ranch where one of the first FAO/UNDP game cropping studies was undertaken in the late 1960s (Blankenship, *et al.*, 1990), bush encroachment was controlled by bringing in local communities to clear the bush in order to make charcoal. This was a win-win relationship with the ranches getting their bush cleared for free and the local people making money from charcoal. On the Kekopey Ranch, at the time, about 21% of the bush had been converted back to grasslands using this method that was also instrumental in improving range and pasture conditions for both wild and domestic ungulates (Blankenship, *et al.*, 1990). Modern range managers must learn to apply techniques used by Africans for centuries, but which until recently and even today were/are believed to be harmful to maintenance of the savannas. Whether they are beneficial or harmful will depend on how, how often, when and where such traditional management techniques are applied, as modern Africans are required to more intensively manage decreasing per capita resources, in this case the savannas needed to maintain wildlife, livestock and humans.

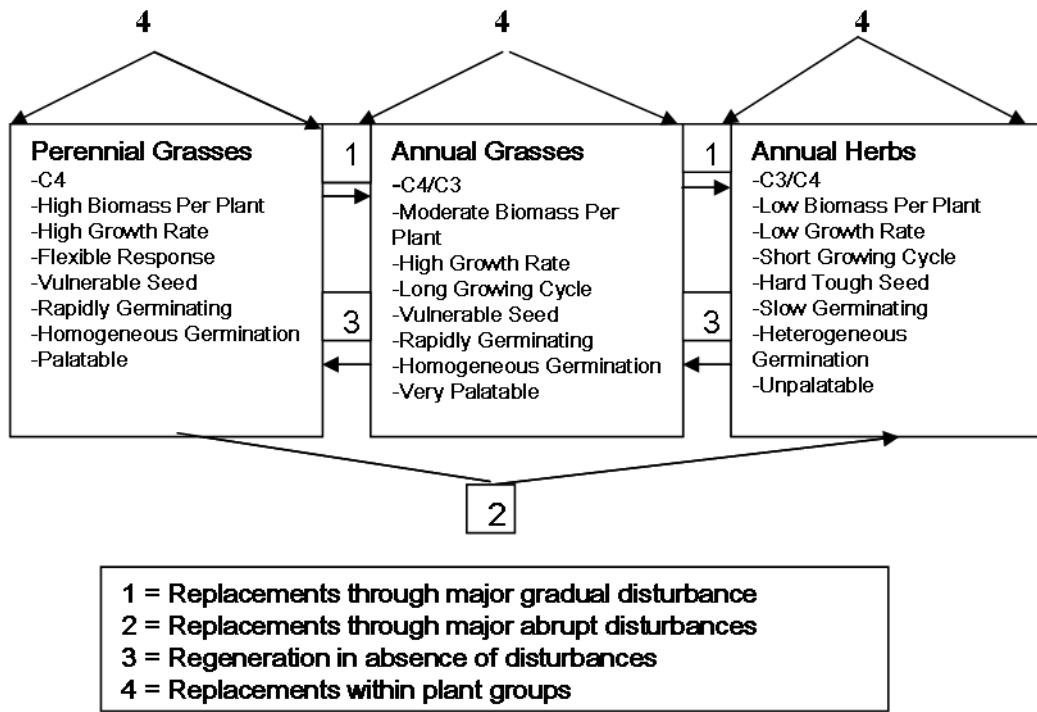

A key conclusion that must be drawn here is that the maintenance of savanna is anthropogenic (human-induced) through fire, harvesting of wood and in combination with grazing of livestock, while wildlife, especially elephant, to some degree play a role in opening up forests. There has always been a delicate balance between humans and savannas dominated by grasses versus dominated by forests (bush component). Take humans out of the equation (e.g., no fire, no harvesting of charcoal and firewood) while maintaining and/or eliminating livestock, and bush encroachment occurs, as on Southern African fenced ranches,

and in the Kruger National Park, among other places. Change humans' traditional nomadism, by, for example, introducing boreholes so that they become sedentary or through the over-population of the 20th century where itinerant farmers, as fallow land disappears, moved into traditional nomadic grazing areas, and savannas are turned into deserts in low-rainfall areas as in the Sahel or portions of Botswana, or bush encroaches in higher rainfall zones. In both cases, the savanna is degraded by modifying the manner in which humans traditionally managed this environment.

6.1.4.5 Impacts of boreholes, over-grazing and over-use of fire on palatable grasses

The structure, species composition and quality of vegetation are related to the rainfall quantity and distribution, as well as soil fertility (see Chapter 5, Section 5.5.2.3, Nutrients, pH, acidity and carrying capacity). Over-grazing by livestock of sedentary herders, combined with heavy burning well into the dry season to try for a second flush of grass, favors poorer quality annual grasses - increasers (Hardin, 1977; Owen-Smith & Danckwerts, 1997 *In: Cowling, et al., 1997*) (e.g., as opposed to perennials. Over-grazing is the result of selective feeding by livestock on the more palatable and nutritious grasses (decreasers), often perennial grasses, resulting in less desirable grasses (often annuals) dominating, and eventually bush encroachment (Figure 6.4). Other adverse consequences of over-grazing are a reduction in carrying capacity for livestock and eventually the land becoming barren. This is especially true during the dry season or droughts, the land becoming subject to severe soil erosion, both from wind and rain. With the vegetation removed and the soil pulverized by the cattle's hooves, the earth is eroded by the wind and the finer particles (silt) collect and are washed by rains to the bottom of slopes where they dry out into an impermeable cement (Hardin, 1977), reducing the land's ability to retain moisture. When it does rain, the

chances of the range recovering are correspondingly reduced (Nana-Sinkam, 1995).

Source: Redrawn from Breman, Cissé and Djitéye, 1982; Rietkerk 1998 both (*In: Lycklama à Nijeholt, et al.*, 2001) with permission, World Wide Fund for Nature (WWF).

Figure 6.4: Dynamics of herbaceous savanna vegetation in response to disturbances

This degradation, associated with boreholes and over-grazing, has permanently impaired the rangeland's potential for recovery and decreased its carrying capacity (Nana-Sinkam, 1995) across much of Sub-Saharan Africa. Over-grazing also favors the increase in invertebrates such as locusts, often resulting in outbreaks of these populations (especially after a few drought years when rains return), as well as certain rodents and hares (de Vos, 1975).

Unfortunately, the above mistakes continue. Well-known South African sport hunter and businessman, Peter Flack noted in a 2003 hunt to Chad that

“the German development company Deutsche Gesellschaft für Technische Zusammenarbeit (GTZ), in yet another well-meaning, unscientifically-researched project, has, once again, used European tax payers’ money to implement a program which devastated the local environment. They have dug dams and drilled a series of boreholes down the eastern side of Chad. This has attracted nomads from far and wide, including Sudan, and has meant that they no longer move on at 3-5 day intervals, but camp around the wells and dams until the water runs out. They have destroyed the vegetation for kilometers around the water points and, in particular, cut down all the dry forest trees, particularly the *Acacia senegalensis*, to feed their herds when the grazing runs out. I saw 1000s of trees felled by nomads. Reduced rainfall and desertification follows this destruction. In addition, it has brought the nomads into conflict with the local people. On one occasion when the nomads loosed their flocks and herds among the ripening crops of the Dadjo people of Dar-Silla, a month before our arrival, over 140 people were killed by gunfire, spear and poisoned arrow, some 40 km from the village. In words of the famous protest song – ‘When will they ever learn, when will they ever learn’! The end result was vast areas of flat, dusty dung-filled, fly-ridden plains, tiny blackened hamlets of conical shaped thatched huts, and domestic livestock everywhere” (Flack, 2003) that pushed out and displaced wildlife.

6.1.4.6 Impacts on pastoralism and range ecology from sedentarization and privatization policies

Spontaneous sedentarization has been driven by a combination of factors that interact and reinforce each other (Niamir-Fuller, 2000 *In: McCarthy, et al., 2000*):

- Major droughts;
- Differential government support of agriculture;
- Lack of government support for transhumance;
- The “benign neglect” syndrome of pastoralism (Swift, 1993 *In: Niamir-Fuller, 2000 In: McCarthy, et al., 2000*);
- Population- and policy-driven extension of cultivation into rangelands;

- Increased competition and conflicts over land, both between pastoral groups and between pastoralists and itinerant farmers;
- Increased individualization and disruption of political structures within pastoral societies;
- Central government claims to “vacant” pastoral land (government-owned farms and national parks);
- Increased ownership by investors outside of the pastoral sector; privatization; and
- Growing economic vulnerability of transhumant groups.

“The major droughts of the 1970s and 1980s forced a mass movement of herders in the Sahel toward the south, with most converting into agro-pastoralists and some completely settling, but it is not known how many have been able to return to their previous transhumance system since then” (Niamir-Fuller, 2000 *In: McCarthy, et al.*, 2000). According to Thébaud (1998 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000), “if after 10 years a sedentarized household has not been able to amass enough capital to reinvest in livestock, it will probably never be able to return to transhumance” (Excerpted with permission from the International Food Policy Research Institute).

Nomadic pastoralists are even induced by governments into becoming sedentary to be more easily controlled by the state (Morris, 1995; GEF, 1998; Moore, Kabore, Gnoumou & Bertelsen, 1999). The independence of the Tuareg in Niger, Mali, Upper Volta and the nomadic Maasai in Kenya and Tanzania frighten their respective governments, who would prefer to see them sedentary and hence politically under government control. Consequently, to keep them in place, there are permanent pumping stations in the Sahel and the “ranches” of East Africa, destroying irreplaceable elements of the human and vegetational mosaic and creating new human-made deserts, all in the name of progress (van Voorthuizen, 1978). Other reasons given for sedentarization of nomads are (Moore, *et al.*, 1999; Adams, 2003 *In: Adams & Mulligan, 2003*):

- Nomads are seen as an ecological and an economic liability;
- The sedentarization of nomads improves both tax collection and use of infrastructure (marketing channels, veterinary posts, water points) (Likewise, Smith (1992) concludes that sedentarization policies allow governments to more easily tax pastoralists.);
- Nomadic pastoralists are seen as wasteful, unproductive, self-destructive and incompatible with modern agriculture;
- The pastoral way of life is viewed as conflicting or as incompatible with the standard of civilized behavior, manners and values; and
- The meat supply shortage in the coastal countries of West Africa was seen as the justification for improvement of livestock policies through sedentarization.

The net result in the Sahel and elsewhere has been environmental degradation (e.g., over-grazing) and conflicts between pastoralists and farmers (Moore, *et al.*, 1999; Niamir-Fuller, 2000 *In: McCarthy, et al.*, 2000; Adams, 2003 *In: Adams & Mulligan*, 2003). Sedentarization policies have failed on both economic and ecological grounds (Sandford, 1983; Homewood & Rogers, 1987; de Haan, 1994 all *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000). Whether forced or spontaneous, these policies have resulted in severe land degradation in semi-arid areas of Sub-Saharan Africa, including reduced vegetation diversity, soil degradation and invasive less palatable grasses in distant pastures from reduced grazing pressure (Niamir-Fuller, 2000 *In: McCarthy, et al.*, 2000). Settlement also results in a loss of traditional knowledge about and controls on range use, leading to less efficient management of the arid resources (Jacobs, 1980; Farah, 1993 both *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000).

“Sedentarization does have positive results—such as providing access to local authorities, education, and health—but the benefits are not as evident for all. Only those elites with means can escape the negative impacts of sedentarization. Customary sociopolitical systems have been subsumed under the hegemony of the central state (nation), leading to a weakening of the traditional leadership, and a fragmentation of authority. The customary judicial system has been relegated to deal with relatively minor internal conflicts. Communally held land (the ownership of which was generally vested in a deity) has been abrogated by the nation-state, often under the pretense that they are not being put to productive use, resulting in a breakdown of common-property regimes” (Niamir-Fuller, 2000 *In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

“The continuing decline in living standards among most mobile pastoralists is manifested by the high rate of out migration toward smaller towns and cities” (Ole Kuney & Lendiy, 1994 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000) or towards large-scale sedentarization, as in Tunisia (Bedrani, 1987 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000) or as in Southern Maasailand increasing sedentarization (see Chapter 9, Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

In Sub-Saharan Africa, a “trend since the 1970s is the increasing concentration of wealth in the hands of a few. It is common to find that about 15% of the population controls 80% of the livestock” (Little, 1985; Sutter, 1987; Ndagala 1991 all *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000) (see Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana). “Increasingly, the large owners are investors from outside the traditional transhumant sector, who entrust livestock to mobile families or hire herders for a wage” (Little, 1985; Turner, 1992; Bassett, 1994 all *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000).

“Often these new owners, to maintain oversight of their wealth, place limits on the mobility of the herd. The gradual disintegration of customary institutions responsible for managing natural resources has provided the opportunity for proponents of privatization to push through their particular agenda of land reform, resulting in widespread alienation of land (Niamir-Fuller, 2000 *In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute)”.

Evidence can be cited from Uganda, in Bazaar (1994 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000); Kenya, in Fratkin (1994 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000) (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya); and Namibia, in Cox, Kerven, Werner and Behnke (1998 *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000). “The rate of land expropriation is so severe now that it has been labeled a ‘land crisis’. Many pastoral advocates and organizations are calling for an immediate moratorium on land titling until land rights can be equitably regularized” (e.g., Niamir, 1994; Salzman, 1994 both *In: Niamir-Fuller, 2000 In: McCarthy, et al.*, 2000) (see Chapter 5, Section 5.7.1, Property Rights and Land Tenure, Constraints to Soil Fertility and Agricultural Production.

Along with introducing sedentarization policies, colonialism greatly reduced slavery and raiding of grain by nomads from farmers, especially in West Africa. This forced an increase in cattle numbers as a “cash crop” to sell and barter for grains and other needs (Smith, 1992). This is believed to also have happened to some degree in East Africa, for instance in Kenya, where European settlers were used to create a buffer between the Maasai and various groups they traditionally raided. In fact, some believe that the pastoral strategy so successfully practiced in the past is no longer possible because of the current inability to undertake traditional transhumance movements due to sedentarization policies (e.g., group ranches in Kenya, loss of floodplains from dams across Sub-Saharan Africa,

encroachment by small-scale farmers on traditional pasture and inability to freely cross borders). With modern-day medicine and veterinary care, the periodic devastation of human and livestock populations is rare (e.g., rinderpest of the 19th century), except in extreme drought conditions and if these are present, food aid keeps people going, often resulting in aggressive confrontational raiding for food, livestock, women, grazing and watering rights or political control (see Chapter 5, Section 5.11.2, Over-population, Desertification and Instability, Nigeria; Section 5.11.4, Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics; Chapter 11, Section 11.8.6, Food Aid and NGOs in Sudan and Section, 11.8.7 Food Aid and War in Somalia).

The *Ujamaa* (*Ujama'a*) village groups of the early 1970s in Tanzania were based “on the re-creation of a ‘self-determination’ type of African socialism based, at least in part, on traditional informal customs, rules, and conventions” (Bruce, *et al.*, 1995; Kirk, 1998; Shivji, 1997 all *In*: Kirk, 2000 *In*: McCarthy, *et al.*, 1997) resulting in a “peaceful transformation of autochthonous land-tenure systems, based on common property and a family economy (homestead), into collective agriculture practiced on state land (*Ujamaa*) by village groups” (Shivji, 1997; United Republic of Tanzania, 1994 both *In*: Kirk, 2000 *In*: McCarthy, *et al.*, 1997). “About 250,000 of them lost the best of their lands and were confronted with restrictions in movement as a risk-coping strategy; village boundaries dividing communal pastures into discrete administrative units excluded them from access to wells and pastures” and had still not been resolved by 1998 (Kirk, 2000 *In*: McCarthy, *et al.*, 1997) (see Chapter 11 Section, 11.8.4, Food Aid and *Ujama'a* Villages In Tanzania).

A real danger lies in pushing pastoralists into becoming sedentary as mixed agriculturalists with livestock. Cultivation allows a population to grow well beyond the limit that simple pastoralism can support, taking grazing land out of

production and increasing grazing pressure on the remaining pasture. This establishes a vicious cycle of human and environmental degradation in marginal areas (de Vos, 1975). The net result is over-grazing, a decline in livestock quality, increased deficiency diseases linked to mal-/undernourishment and parasitic infections (Darling & Farvar, 1972 *In: de Vos, 1975*), and the threat of disease epidemiology in livestock (e.g., rinderpest). By the end of the 20th century, this was happening among the Maasai in both Kenya and Tanzania, since factors like group ranches in Kenya and land confiscation in both Kenya and Tanzania have squeezed and compressed Maasai into areas too small to support traditional nomadism, and which in many cases lack sufficient dry season grazing, if any, to support viable herds.

“The ranching model (Kenya) encouraged sedentarization, destocking, and water development. However, these were unsuccessful in increasing livestock productivity, at best, and in some cases were very destructive in the long run” (Sandford 1983 *In: Niamir-Fuller, 2000 In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

The result is over-grazing and creation of dry season dust bowls, as readily seen in Northern Maasailand on the main road between Arusha and the Kenyan border, and/or the conversion of land into small farms by Maasai or even the questionable sale of land to small or commercial farmers in Southern Maasailand, as well as around Amboseli (small-scale farmers) and Maasai Mara (commercial wheat schemes) (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya and Chapter 9, Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

Since 1961, the area farmed in Chad, Burkina Faso, Mali and Niger increased by over 4 million ha. This expansion involved mainly the conversion of large areas of “Common Property Resources”, such as forests, wetlands and rangelands into

cropland, with farmers overriding and ignoring the traditional use rights of other groups to these resources. Politically powerful groups and elites with preferential links to various organs of the state (e.g. civil servants, wealthy traders and religious leaders) frequently appropriated “Common Property Resources” for their own use and in the process introduced new use and management structures. In Senegal, there are several accounts dating back to the 1950s of how the powerful Mouride Islamic brotherhood had been able, with government backing, to convert large tracts of communal rangelands into peanut fields. In 1991 alone, the Senegalese government gave permission for 45,000 ha of forests (forested savanna) to be converted to peanut fields (GEF, 1998; Williams, 1998). Much of this was critical grazing lands for pastoralists (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal). This pressure continues in the 21st century as the Mouride brotherhood attempts to take over 44,000 ha of the 87,500 ha Ranch du Doli, most likely to be deforested and converted into more peanut fields (Gning, 2004). Smith (1992) believes that the expropriation of traditional pastoral lands by the governing elite is a problem across Sub-Saharan Africa, with pastoralists being the last to have a say over central government policies. Smith (1992) also believes that by ignoring traditional land use management practices, absentee herd-owners and their stock may be exacerbating range degradation – very likely mining range resources for short-term gain of secondary incomes (see Chapter 3, Section 3.4.2.3, The legal exclusion of the African hunter from his wildlife, Loss of Hunting and Territorial Rights by “San” Bushmen, Botswana and Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana). One could argue that this problem exists with other resources, including wildlife, timber, fishery and mineral.

Furthermore, as livestock management became more intensive, wildlife became increasingly unwelcome, competing for pasture as well as becoming a reservoir

for disease (e.g., rinderpest, foot and mouth, bovine pleuro-pneumonia, sleeping sickness, etc.) (Adams, 2003 *In:* Adams & Mulligan, 2003) (see Chapter 9, Section 9.7.8.2 “Politics of despair”, Southern Maasailand “Tarangire Ecosystem” and Chapter 11, Section 11.11.9.2, Impact of donor driven conservation on private lands, Clive Aggate, Kifluku, Laikipia, Kenya).

6.1.4.7 Impacts on pastoralism and range ecology from increases of human and livestock populations in the 20th century

It is estimated that the human population in Sub-Saharan Africa has increased 5.5-6.5 times from between 95.9-114 million to 622 million between 1900 and 2000. Between 2000 and 2050, the human population is expected to increase 2.4-2.8 times reaching between 1.497 and 1.753 billion. Between 2000 and 2100, the human population is expected to increase 3.1-4.4 times to between 1.944 and 2.750 billion (see Chapter 5, Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY). All of the above policies and misused technological interventions have been compounded by this population explosion, both human and livestock, from improved medical and veterinary care linked to colonialism.

Along with improved veterinary care, increasing human populations demanded more livestock. Livestock for many cultures was required for “bride price”, as a means of barter, as a sign of wealth and most importantly, for nutrition (e.g., fresh milk, curd/*lait caillé* and blood depending on the pastoral group). In addition, it was convertible to food (e.g., rarely slaughtered on special occasions or during extreme drought, or traded for grains and other necessities), or even currency in times of extreme deprivation such as during a drought. Thus, there is a resistance to reduce livestock numbers, as they are the savings in a pastoralist’s “traditional bush bank account”.

In Sub-Saharan Africa, when we speak of over-grazing by domestic stock, we are often referring to a human population, which has exceeded the carrying capacity of its environment. Each individual family, in order to survive, must keep a certain number of livestock. Therefore, as the human population goes up, so does the livestock population and the pressure on the grasslands. If the population of livestock is high at the beginning of a wet period, the livestock will breed up, grossly exceeding the carrying capacity of the range, and unless there is an offtake, habitat degradation will occur. When a dry cycle returns, a massive die-off takes place, sometimes amounting to as much as 40% of the livestock (Brown, 1971 *In: de Vos, 1975*).

The FAO estimated that Africa's cattle population of 170 million in 1986 would grow to 200 million by 2010. In 1986, they estimated that the overstocking rate in many places was 50 to 100%. It is estimated that Tanzania's pre-rinderpest pre-1890s cattle population of 4.5 million had grown to more than 15 million by the late 1980s and Botswana's national herd increased 2.5 times to 3 million between 1965 and 1976. The World Resources Institute in the mid-1980s estimated that 90% of the Sahel-Sudan grasslands and 80% of the Southern Africa's grasslands were over-grazed (Rosenblum & Williamson, 1990). Total livestock populations for Sub-Saharan Africa from 1961-2003 are estimated in Table 6.2, the total number increase averaging 2.3 times from 276 to 622 million animals with an annual population growth rate of 2.3% between 1961-2003.

While in 2003, camels made up only 2% of Sub-Saharan Africa's livestock population, they are crucial to the survival of herders in extremely arid areas. Among the Gabbra of the Kenya/Ethiopia border, they can supply as much as 60% of the milk during the peak of the dry season. They can satisfy their water needs from vegetation once the rains have come, going months without drinking. As the quality of the vegetation decreases during the dry season, they will need to drink more often (Smith, 1992). In northern Kenya, innovator rancher Jasper

Evans in the early 1990s introduced high milk yielding camels from India to groups such as the Samburu, as a means of providing them with milk. At the same time, the hope was that by introducing these browsers, the reduction in numbers of grazers (e.g., cattle, goats and sheep) to sustainable levels would be encouraged, thereby taking pressure off the grasslands as a means of decreasing habitat degradation in tribal areas.

Small stock (sheep, goats and pigs) make up about 63% (62% in 2003, Table 6.2) of the livestock population in Sub-Saharan Africa and are owned by the poor who cannot afford cattle (Smith, 1992). The tremendous increase in these small stock (pigs/4.9 times, goats/2.6 times and sheep/2.3 times) between 1961 and 2003 (Table 6.2) could be an indication of the increasing number of rural and even urban poor in relation to wealthier cattle owners. Also, as grazing lands become degraded, cattle will continue to browse although they are primarily bulk grazers, while small stock are better browsers (e.g., sheep 21.6% browse in their diet and goats 47.5% browse) and require less water (Smith, 1992) and thus are able to survive under degraded conditions. Thus, this increase in browsers relative to cattle could also be an indication of range degradation.

As discussed, as human populations increase and the availability of prime agricultural land and fallow periods disappears more and more, dry season pasture and water resources have been taken over by agriculturalists. Rainfed agriculture is being extended into lower and lower rainfall zones, former rainy and dry season pastures, often accelerating severe land degradation (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal and Section 5.9.4.7, Deforestation in savanna environments). Meredith (2004) estimates that between 1973 and 1988, Africa lost 6.1 million ha (15 million acres) of pasture.

Table 6.2: Livestock numbers Sub-Saharan Africa, 1961-2003

Date	Cattle	Sheep	Goats	Horses	Asses	Mules	Pigs	Camels	TOTAL
2003	208,352,575	164,777,455	202,072,659	2,879,762	9,036,695	293,070	20,074,510	14,557,108	622,043,834
% Of Total 2003	34%	27%	33%	0.5%	1.5%	0.05%	3%	2%	
1986	159,030,517	113,942,082	136,344,214	3,630,146	8,622,960-	545,440	11,865,890	13,136,095	447,117,344
1961	103,877,126	71,228,652	77,629,399	2,289,396	7,508,281	1,330,444	4,100,825	7,661,448	275,625,571
Times Increase 1961-2003	2.0	2.3	2.6	1.3	1.2	Decline	4.9	1.9	2.3
% Annual Population Growth Rate	1.7	2.0	2.3	0.5	0.5	-	3.8	1.52	1.9

Note: Percent Annual Population Growth Rate: (Years x r) = $[\ln(N_t) - \ln(N_0)] \times 100$, Where N = Population at Time "Zero" and Time "t," and "r" = Percent annual population growth rate

Access to dry season water points becomes more and more restricted, as the water and the surrounding lands are utilized or occupied by farmers. In addition, more and more farmers that used to allow pastoralists to use their crop residues for their livestock are now using all the residues for their own small stock (GEF, 1998) and/or for fuel supplies. In the past, this residue along with manure from cows feeding on the residue helped fertilize the land in the form of green or cow manure (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel; Section 5.9.4.6, Deforestation in afromontane forests, Rwanda, Over-Population and Land Degradation Linked to Deforestation for Agriculture and Political Destabilization; Section 5.12.1.1, Integrated nutrient management (INM); Mitigation of Nutrient Mining in the Groundnut Basin of Senegambia, West Africa Section and 5.13.2, Net Results of Colonial and Post-Independence Periods on Sub-Saharan Agriculture).

The take over of their land combined with drought and habitat degradation is forcing many pastoralists southward. The drought of the mid-1970s and mid-1980s stimulated a significant migration of pastoralists and livestock from the arid to the sub-humid parts of West Africa.

“Countries with large percentages of arid land have witnessed reductions in their cattle populations, while countries with large percentages of more humid land have witnessed substantial increases in their cattle population. For example, between 1975 and 1987, cattle populations decreased in Senegal ($-1.8\%/\text{year}$); stayed constant in Mauritania; increased slowly in Mali ($1.6\%/\text{year}$), Niger ($2.3\%/\text{year}$), and Chad ($1.3\%/\text{year}$); and increased rapidly in Cameroon ($4.1\%/\text{year}$), Central African Republic ($8.7\%/\text{year}$), and Cote d’Ivoire ($5.8\%/\text{year}$)” (ILCA, 1993 *In: Swallow & McCarthy, 2000 In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

Fulani herders from the Sahel began permanently moving southward in the middle of the 20th century, invading countries such as northern Ghana because of degraded habitat associated with boreholes, increased human populations, loss of dry season grazing land on floodplains and compounded by the drought of the 1970s/80s. The last three decades have also been characterized by a further change in the pastoral migratory pattern. Fulani herdsmen have moved even further southwards (beyond the savanna zone) to the fringes of the humid tropical forest. These movements towards the forest zone have been observed in all the coastal countries of West Africa. Fulani herd owners from Burkina Faso and Mali have been attracted to the Ivory Coast by the lure of better pasture, lower population densities, proximity to markets, the availability of veterinary care and subsidies provided by the Ivorian state livestock parastatal (Chapter 5, Section 5.7.4.4, Land reform and civil war in the Ivory Coast). In addition to the environmental and ecological factors, the ability of the migrant Fulani herdsmen to establish reciprocal relations with the host population largely explains their migration and settlement in northern Ghana (Tonah, 2002). The principal author has seen Fulani (Bororo) herders as far south as the tropical lowland forests of Southeastern Cameroon, literally side by side with the Pygmies and gorillas. Similarly, Greig (*pers. comm.*) has seen Fulani herders crossing the CAR border into Congo Brazzaville as forest roads are opened. De Haan, *et al.*, 1997 note that

“in the eastern area of the Central African Republic, the incursion of Fulani pastoralists with their cattle in the tree parklands of the Zande people leads to:

- Increased openings in the forest cover.
- Decrease in animal biodiversity.
- Degradation of the hunting potential of the Zande, and thus the quality of their diet.
- Loss of the traditional values of the Zande people”.

This is also resulting in armed conflicts. In February 2004, 50 Christians were reported killed by Muslim warriors in the town of Yelaw in central Nigeria. This

appears to be in retaliation for Christian attacks on Muslims and friction over-grazing rights (Giardino, 2004) (see Chapter 5, Section 5.11.2, Over-population, Desertification and Instability, Nigeria). As land resources become scarcer, these conflicts are expected to increase in the 21st century in the savannas of Africa between pastoralist groups and between pastoralists and small-scale farmers as farmers move into marginal lands. Guest (2004) also explains, similarly to what is discussed in Chapter 13 (Section 13.8.6, Former Cold War allies vying for power in the Great Lakes Region and Section 13.10.1.6, Oil-scorched earth Sudan), that the British/European system of “divide and rule” favored Christian missionaries and universities in the south, while keeping the Moslem Fulani and Hausa in the north of Nigeria backwards and uneducated. This increased religious and ethnic tension eventually resulted in a “northernization” program of training and attempts to bar southerners from holding public administrative posts, winning public works contracts, running shops or owning land in the north, all of this adding fuel to the fire. The conflict in Darfur is occurring for similar reasons (Chapter 5, Section 5.11.4, Darfur, Sudan, over-population, desertification, ethnicity, conflict and politics).

6.1.5 Possible Way Forward

Given that in the savannas of Sub-Saharan Africa, traditional pastoralism along with wildlife is ecologically considered the best land use,

“The main tenure implications are the devolution of authority to local groups, the ability to respond quickly, simple rules, and the need for access to or incorporation of a range of agro-ecological areas into the tenure system” (Lane & Moorehead, 1994 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute) (see Section 6.1.2, Carrying Capacity and Sub-Saharan African Savannas).

As with wildlife and other resources, there is a movement afoot to take a step backwards in order to ultimately go forward, devolving tenure and control over pasture management back down to the local level (Table 6.3).

Table 6.3: Comparison between the "conventional" colonialism/independence and the "opportunistic" approaches to pastoral tenure in dryland Africa

AREA	CONVENTIONAL APPROACH	OPPORTUNISTIC APPROACH
Tenure	Fixed tenure regimes: privatization (or exclusive communal)	Flexible tenure: complete mix of overlapping and integrated regimes
	Conflict issues largely ignored	Focus on negotiation, mediation and arbitration
Objectives	Registration, land title	Alternative and innovative mechanisms for securing overlapping claims
	Secure investments in open range improvements (legumes, fodder trees, paddocks, fences and water	Secure access rights to pastoral key resources (including home area and drought preparedness)
Costs	High - for the surveying, registering and administering of titles required with private property	Low – for effective allocation under communal-tenure systems
Driving Forces	National government policies: <ul style="list-style-type: none"> • Nationalization of resources • Sedentarization of the herders • Privatization of the range 	Interests of pastoralists: <ul style="list-style-type: none"> • Flexibility in resource use • No restriction to mobility • Reciprocity in access rights
Underlying Theories of Land Tenure	The “ <u>tragedy of the commons</u> ” theory	The property rights school New Institutional Economics

Source: Grell & Kirk (2000, Table 2.1 *In: McCarthy, et al., 2000*) with permission, (IFPRI).

Today, there are movements afoot to combine the best of both worlds, namely traditional controls integrated into more intensive management systems. In general, Oxby (1975 *In: Smith, 1992*) suggests that many African governments are unwilling to recognize traditional pastoralism as a viable way of life and contributor to the wealth of a nation. He recommends that the following needs of voiceless pastoralists be recognized (Oxby, 1975 *In: Smith, 1992*):

- Control over encroachment by sedentary agriculturists onto land used by pastoralists.
- Protection for rights of way through cultivated areas.
- International agreements to allow the movement of herds and herders to traditional pasture and markets, implying free movement across national borders necessary for their survival.
- Ensuring pastoralists receive a reasonable share of proceeds from sale of their animals for meat.
- Phasing out deep wells and boreholes in favor of smaller shallow wells maintained by pastoralists themselves.
- More emphasis on pasture and fodder projects, rather than water.
- Giving pastoralists access to mobile support services, discouraging concentration around central points. This includes *écoles nomads* (mobile schools including adult education), mobile clinics/paramedics and roving veterinarians.

6.1.5.1 Cross-border transhumance agreements between the Ivory Coast, Burkina Faso and Niger

“Bilateral agreements have been developed between Ivory Coast, Benin, Burkina Faso and Niger that fix regulations for transhumance and the principle of authorization of transhumance between the countries. Specifically they include the following” (van der Linde, Oglethorpe, Sandwith, Snellson & Tessema, 2001):

- “Foreign herders will receive the protection of the host authorities and their rights are guaranteed by the judicial structures of the host country.
- Herders have to respect the laws of the host country.
- Herds have to be guarded continuously by a sufficient number of herders.
- Herders are required to keep, and produce upon request, an international transhumance certificate (showing origin, destination, composition of the herd and the vaccinations received).

- Every country has to specify the places where animals can officially enter and leave the country.
- The host country has to fix the period, duration and number of animals authorized for a stay in the country during the transhumance circuit (van der Linde, Oglethorpe, Sandwith, Snelson & Tessema, 2001)”.

Transhumance cross-border movements are occurring with or without official agreements across Sub-Saharan Africa. Agreements, as above, may provide some legal protection to pastoralists and also help in a collaborative effort with local herders to better manage grazing lands on the subcontinent.

6.1.5.2 Decentralization and creation of pastoral associations in West Africa

As part of the decentralization process, pastoral organizations (PO) have been organized throughout West Africa as a new type of community-based NRM institution.

“The POs treat all types of institutional arrangements that regulate individual and collective actions by pastoralists in an attempt to safeguard and promote their economic, social, cultural and political interests. They are legally organized by the government and dependent on the state for technical assistance, supplies and financial resources (Vedeld, 1992 *In: Moore, et al., 2000*). The functions of the POs are related to acquiring secure land tenure, resource management, provision of services, communication of information, external relations and the building and maintenance of community coherence and morale. Key factors that determine the viability of POs include food security, water security, land security, herd ownership, credit, veterinary services, marketing, economic self-sufficiency and literacy (Shanmugaratnam, *et. al.*, 1992 *In: Moore, et al., 2000*). Although POs have been successful in organizing pastoral communities, integrating the POs with the GT (*Gestion des Terroirs*) and other management systems remains problematic” (Moore, *et al.*, 2000) (see, Chapter 5, Section 5.12.3, Decentralization and Chapter 9, Section 9.8.9 *Gestion des Terroirs*, West Africa).

"In Niger, it has taken the form of a legislative reform of land tenure and natural resource management policy conducted over a 10-year period from 1985 to 1994. In Burkina Faso and Mali, land use planning based on the concept of "village territories" (or gestion des terroirs) has become very popular. In all cases, governments have sought to clarify tenure issues and reinforce the rights of local communities to manage their resources through granting of legal recognition and decision-making authority...While experience with implementing these new programs is still limited, they nevertheless represent a departure from the top-down, centralized resource management policy of the past. However, simply assigning authority to local users, without ascertaining the range of uses of a resource, the diversity of interests among users and the capability of existing local institutions to take on additional responsibilities, will only complicate rather than solve the problems associated with the appropriation and management of CPRs (Common Property Resources). This is because CPRs in the region have multiple functions and are exploited by a wide variety of user groups...Failure to recognize the rights of all existing users will lead to the appropriation of key resources by the more powerful groups or those practicing a particular system of production, which may eventually result in social conflicts or inefficient utilization of the diverse set of CPRs. This is one reason why the village territory approach has come under criticism. Because the concept is more applicable to settled farming villages with a clearly defined territory and set of resources, it has been argued that there is a danger that the approach may empower sedentary farmers to exclude transhumance pastoralists from grazing resources they previously had access to, especially where the farmers themselves are beginning to manage their own animals" (Lane & Moorehead, 1994 *In: Williams*, 1998).

Moore, *et al.* (1999) draw similar conclusions. Grell and Kirk (2000 *In: McCarthy, et al.*, 2000) also note that even today

"the perception of pastoral tenure in the Francophone countries is much biased toward centralization, with priority being given to agricultural land use and the conventional approach of exclusive private property". "A herder (Peulh/Peul/Fulani) can never take possession of land' was the statement of a village chief at a workshop held in 1996 on conflict management in Bobo-

Dioulasso” (PRASET, 1996 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

Ouédraogo (1997 *In:* Bouderbala, Cavérvrière & Ouédraogo, 1997 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute) “referring to pastoral-tenure rights, points out that West African herders in all workshops have always insisted that the goal of pastoralists is not to lay claim to private pastoral property, but rather to participate in property regimes and to secure access-rights for herders”.

“However, as they (pastoralists) are not present on a permanent basis, their specific interests often are forgotten when decisions are being made on the village level. This has been recognized as a weakness of the ‘gestion des terroirs’ approach (Marty, 1996a *In:* Lycklama à Nijeholt, de Bie & Geerling., 2001), and efforts are being made to improve the position of herders in the village level decision making process and to secure their access to resources in different ecological zones” (Lycklama à Nijeholt, *et al.*, 2001).

“The typical approach of *gestion des terroirs*, or land use planning, is oriented toward a geographically well-defined area in which the land use planning takes place. This is the right approach in environments with sufficient rainfall, and where land use systems are based on farming or ranching. However, non-equilibrium environments differ essentially in that the mobility of herds is the crucial factor for sustaining livelihoods” (Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

The following shortcomings have been identified in the literature on the subject (Marty, 1993; Painter, Sumberg & Price, 1994; Engberg-Pedersen, 1995 all *In:* Niamir-Fuller, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute):

- “Existing informal local institutions for decision making are often overlooked.

- Significant differences between the interests of leaders and non-leaders are ignored.
- There are inconsistencies between the approaches' goals for natural-resource management and villagers' goals for infrastructure and social development.
- Government was unable to provide adequate incentives for people to undertake resource-conservation activities that are labor intensive and have noticeable returns only in the long run.
- The high spatio-temporal variability of resource endowment in dryland areas is underappreciated, as evidenced by the focus on promoting exclusionary mechanisms in land-tenure systems.
- The focus on the village (or groups of villages) is spatially myopic.
- Mobile pastoralists are ignored or delegated to a secondary 'receptive,' rather than proactive, position".

Elbow (1996 *In:* van der Linde 2000 *In:* McCarthy, *et al.*, 2000) has found that *terroir* land use planning is favored by French development agencies and by governments of former French colonies in the Sahel.

"The concept of *terroir* is originally an analytical unit describing the physical space on which sedentary villagers get most of their means of subsistence. This analytical unit is now used as an intervention unit in a drive to give rural communities greater responsibility in the management of their resources. Although it may be early to assess the impact of the *terroir* approach on land tenure, some elements need to be highlighted here. Because it has essentially been used as a concept linked with sedentary agriculture, the concept of *terroir* is not compatible with highly mobile lifestyles (Painter, *et al.*, 1994; Marty, 1996b both *In:* van der Linde, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

"Since the *terroir* approach as it now stands may lead to the risk of further marginalization of herders" (Marty, 1993; Toulmin, 1993; GTZ 1995; Winckler, Rochette, Reij, Toulmin & Toé, 1995 all *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000), "one proposition is to concentrate on access rights to key resources or focal-point management", which according to Behnke (1994 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute) will:

- “Concentrate management attention on the essential resources of the production system and devote much less effort to the clarification of property rights.
- Allow producers who control key natural resources to exploit more peripheral resources and exercise de facto control over these resources.
- Permit the continuation of customary tenure arrangements that encourage the shared use of resources that are not in high demand by de-emphasizing the need for strict boundary maintenance”.

According to Grell and Kirk (2000 *In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute),

“The answer is community-based natural-resource management/CBNRM (*gestion des ressources naturelles à base communautaire*), which combines both the land and the resource dimension in an approach based on common-property rights. The focus is on key-resource management and the necessary institutional arrangements that allow all user groups to participate...However, very few of these projects have tackled the ‘problem’ of mobility. Only a few projects have attempted to implement this approach among mobile pastoralists...The Community Based Resource Management approach is far better suited to mobile pastoralism than any other approach; however, it must deal with the issue of scale. Mobile pastoralism requires large-scale management of contiguous land” (Niamir-Fuller, 2000 *In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute).

Grell and Kirk (2000 *In: McCarthy, et al., 2000*, Excerpted with permission from the International Food Policy Research Institute) go on to recommend:

- Division of responsibilities and decision-making must be clearly spelled out and devolution as in CBNRM in general must be to the lowest possible level, while being wary of the concept of homogeneous groups of pastoralists or any other user groups with the likelihood of

privatization of resources and increased disparities between individuals and groups as population pressures grow and resources become commercialized.

- Democratic legitimization of pastoral organizations with the question of internal democracy at a number of levels is still an issue (Mortimore, 1997 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).
- Herders' attitudes must change from an opportunistic management strategy of what they can get to rather what they can do (Ly, 1998 *In:* Grell & Kirk, 2000 *In:* McCarthy, *et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute). Pastoral reform is currently still being driven by outside researchers and donor advisors rather than the herders themselves who cry for help but are not proactive.

de Haan, *et al.* (1997) recommends the following conditions in reestablishing local management over pastures:

- Increasing the costs of grazing in order to reduce animal pressure promoting earlier off-take.
- Levying grazing fees for communal areas.
- Full cost recovery especially for water supply and animal health services; water often seen as a free resource supplied by the public sector (e.g., in form of boreholes and their maintenance).
- Removal of price distortions for other agricultural inputs to reduce the conversion of key pastoral resources into marginal crop land.

“Decentralization alone will not solve the problem of transhumance, which affects more than one local administration and several areas” (Mortimore, 1997 *In:* Grell & Kirk, 2000 *In:*

McCarthy, *et al.*, 2000). “Pastoral mobility must be ensured through negotiation and renewable accords supported by reorganization of the territories, delimitation of administrative boundaries, and the empowerment of local institutions” (Grell & Kirk, 2000 *In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).

There is a need to provide support for the formation or strengthening of local organizations where they are non-existent or weak. Institutional strengthening and training can be provided by government agencies in such areas as management and leadership skills and program planning. In addition, local users generally possess inadequate scientific knowledge to complement their own indigenous knowledge as they move into more intensive management situations. Yet, access to reliable information on resource conditions and the effects of different resource use patterns is essential for the long-term management of “Common Property Resources” and the sustenance of livelihoods that depend on them. State institutions can assist local users by carrying out environmental assessments of resource use patterns and determining resources, which are being degraded or at risk, and providing training on improved management techniques (GEF, 1998; Williams, 1998) and resource monitoring. This implies a need to select youth from these areas for advanced vocational training at a secondary and tertiary level. If boreholes are present or planned, the movement of livestock and the opening and closing of these boreholes must be carefully planned and managed by trained technicians from the communities. To date the reality on the ground in key countries is:

- **Niger:** The Rural Code of 1993 is biased in favor of agricultural land and does not correspond to the reality of pastoral-resource management, which is directed toward access rights to natural resources and not to private ownership of land (Grell & Kirk, 2000 *In: McCarthy, et al.*, 2000,

Excerpted with permission from the International Food Policy Research Institute).

- **Mali:** The legal recognition of herder organizations and the pastoral vocation of land (*domaine pastoral*) is part of the actual process of decentralization being land-oriented rather than resource-oriented, with 10,752 villages having formed 682 rural communes where expectations for local development are high (Michel, 1998 *In: Grell & Kirk, 2000 In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute). Concern exists that “cutting up the country between the communes will increase sedentarization of herders in home areas (*terroirs d’attaches*) and lead to further weakening of the existing, traditional pastoral tenure with regard to transhumance movements” (Soumaré, 1997 *In: Grell & Kirk, 2000 In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).
- **Burkina Faso:** The land organization reform, *Reforme Agraire Foncière*, was adopted finally in 1997, but concrete acts on procedures for property rights, especially common-property rights on pasture lands, have not been passed...However, the official approach on pastoral land-tenure is still orientated toward grazing reserves, or zone pastorals (Sanon, 1996 *In: Grell & Kirk, 2000 In: McCarthy, et al.*, 2000), and sedentarization of herders, with a coercive regulatory approach (Zeba, 1996 *In: Grell & Kirk, 2000 In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).
- **Guinea-Conakry:** Guinea-Conakry is the first country in West Africa that has adopted a Pastoral Code (*Loi du 29 Août 1995 Portant Code*

Pastoral). In general, access to pastoral areas is free (Article 14). The law recognizes the pastoral use of natural resources (*à des fins pastorales*) and defines access rights (*droits réels particuliers*) with the restrictions of not overusing the resources and of respecting customary rights of other users (Articles 75–76) (Grell & Kirk, 2000 *In: McCarthy, et al.*, 2000).

- **Ethiopia:** “National institutions are afraid that they may inadvertently open a loophole for the displacement of farmers from their holdings through the implementation of certain tenure policies” (Grell & Kirk, 2000 *In: McCarthy, et al.*, 2000, Excerpted with permission from the International Food Policy Research Institute).
- **Namibia:** All people of Namibia have the constitutional right to settle themselves at any place in the country. Together with the uncertainty about rights and the authority of traditional leaders and local government, this fact contributes to an uncontrolled exploitation of rangelands and resources of local communities by outsiders. A possible solution might be to distinguish between the ‘right to settle’ and the ‘right to use’ the resources (Kruger & Kressierer, 1995 *In: Grell & Kirk*, 2000 *In: McCarthy, et al.*, 2000). With regard to pastoral tenure, this entails, under the specific conditions present in Namibia, a combination of a private-property (ranching) model and a common-property model in areas where priority in access to pastoral resources is given to the local herders (Grell & Kirk, 2000 *In: McCarthy, et al.*, 2000) (see Chapter 9, Section 9.7.2.1, Devolution through policy reform, land and resource tenure).

6.1.5.3 The old and the new on Ol Maisor Ranch, Laikipia, Kenya

The Laikipia ranch area is unique in a number of ways. This area contains about 31 major ranches ranging from some as small as 3,644 ha (9,000 acres) to others as large as 48,583 ha (120,000 acres). While black Kenyans own some of the ranches (e.g. retired General Lenges of the Kenyan Army, the Ol Doinyo Lemboro Ranch (Samburu), one owned by a Maasai), most are white-owned, and a number are owned by non-resident Europeans or Americans who do not rely on these ranches for survival. These ranches are bordered in the north by Samburu Mukogodo Maasai Tribal Lands and are slowly being encroached upon on their southern borders by smallholder farmers coming from the over-crowded Kikuyu Highlands, who are being permitted to buy land that should never be put into farming because of the low rainfall and poor soils (see Chapter 3, Section 3.11.1, Population, Kikuyu and the Mau Mau and Chapter 11, Section 11.11.9, Kenya Wildlife Service (KWS) – Living on donor handouts, negative impact on Kenya's wildlife outside parks). The area contains significant populations of wildlife, including the second largest elephant herd in Kenya: 3,436 elephants compared to nearly 8,056 in the Tsavo region (King, Kahumbu, Omondi & Douglas-Hamilton, 1999). The Laikipia area is extremely important with regard to the future of wildlife outside of Kenyan parks and reserves, not only because of the numbers of wildlife found on private lands, but also because of the practical knowledge base that ranchers have with regard to wildlife, livestock and range management. In addition to elephant, wildlife found on the Laikipia ranches includes but is not limited to Grevy's zebra (*Equus grevyi*), Thompson's gazelle (*Gazella thomsonii thomsonii*), Northern Grant's gazelle (*Gazella granti notata*), Cape buffalo (*Syncerus caffer caffer*), East African impala (*Aepyceros melampus rendilis*), lion (*Panthera leo*) and cheetah (*Acinonyx jubatus*) (Evans, *pers. comm.* In: DeGeorges & Pellek, 1991). This wildlife will serve as an important nucleus to restock traditional group ranches in the area, once Kenya gets its wildlife laws and

policies corrected (see Chapter 9, Section, 9.6.1.2, Kifluku Farm, Laikipia, Kenya and Section 9.8.7, Ngwesi Lodge, Mukogodo Pilot Tourist Program, Kenya, as well as Chapter 11, Section 11.11.9, Kenya Wildlife Service (KWS) – Living on donor handouts, negative impact on Kenya's wildlife outside parks).

Because of East Coast Fever, cattle have to be dipped weekly or every ten days. Soils and forage grasses/plants in the area are deficient in magnesium, iodine, copper, phosphorous and calcium. A formula with these minerals is prepared and put into drinking troughs for the livestock. Low calcium and phosphorous in the diet can result in stillborn animals and broken bones (DeGeorges & Pellek, 1991).

Ol Maisor is an unfenced 12,146 ha (30,000-acre) ranch in Rumuruti (Laikipia Highlands) owned by innovator farmer Jasper Evans. This ranch has no dry season grazing habitat. Evans has developed an African solution to an African problem. This solution takes Western management concepts but uses traditional knowledge of the Turkana (DeGeorges & Pellek, 1991; Powys, 2003) and Samburu herdsmen (DeGeorges & Pellek, 1991) as to when grazing pressure is to the point that the livestock should be moved. Instead of expensive wire fencing, Acacia branch night *bomas* protect the livestock from predation, since fencing is continually stolen. Fifty small minimal maintenance rainfed catchments strategically located about the ranch have been turned into ponds/watering points created by using a locally designed “dam scoop” attached to a camel or cow. In the early 1990s, 2-3,000 cattle were maintained on the ranch at a stocking rate of one cow per 4.1 ha (10 acres) (DeGeorges & Pellek, 1991). Powys (2003) believes that one cow/7.3 ha (18 acres) is more accurate. Herds are generally organized into 100-200 animals. Each herd spends six to eight weeks grazing in the vicinity of a dam and is then moved onto a new dam site and thus grazing area. This movement is based on a decision made jointly between the ranch manager and the herder. This ranch also runs approximately 2,500 head of sheep

and goats and 500 camels. Unless there are very dry years, both water and grass are adequate to maintain the herds on Ol Maisor. Techniques such as buying undernourished extensively grazed cattle from the tribal areas and then intensively grazing them for a couple of months prior to selling them to the abattoir are other innovative ways of maximizing the carrying capacity on marginal lands that are employed by Jasper. Rotational burning takes place every three years to eliminate moribund grasses, stimulating grass growth/production and livestock production (Evans, *pers. comm.* In: DeGeorges & Pellek, 1991).

6.2 BOREHOLES AND WILDLIFE

Wildlife reacts similarly to livestock with regard to ill-placed boreholes and watering points by over-grazing. On the other hand, properly placed watering points can be used to spread out the game, as with cattle, diffusing pressure on habitat that might otherwise be over-grazed, when game like cattle concentrate around a few sources of water. All of this implies active management, going so far as to open and close watering points as a means of moving the game about to take advantage of the complete array of habitat.

6.2.1 Boreholes and Wildlife, Kruger National Park, South Africa

Nowhere is the impact of watering points and boreholes on wildlife better demonstrated than in the intensively managed parks and game reserves of South Africa. These examples demonstrate how little is known about the interrelationship between species and how species relate to various changes in biotic and abiotic parameters within the environment.

The Kruger National Park covers an area of 20,000 km² in the eastern lowveld of South Africa. When the Kruger National Park was established in 1926, areas between perennial rivers were largely devoid of permanent water.

“Reasons given for the stabilization of the water supply included: making the more arid areas accessible to game in order to spread the animals more evenly over the whole KNP; discouraging the emigration of animals out of the KNP before it was fenced; blocking of migration routes after it was fenced; prolonged droughts; and the deteriorating state of perennial rivers” (Pienaar, Biggs, Deacon, Gertenbach, Joubert, Nel, Van Rooyen & Venter 1998 *In: Brits, 1999*).

By 1970, five medium-sized dams and 32 water points, supplied from boreholes by wind mills were constructed in the northern 1,300 km² range of the roan antelope. By 1976, there were nine dams and 46 wind mills, and by 1994, 11 dams and 59 wind mills in the northern portion of the park (Harrington, Owen-Smith, Viljoen, Mason, & Funston, 1998; 1999). The Kruger National Park as a whole has “at present 283 artificial watering points where drinking water for large herbivores is supplied in troughs, 42 concrete dams and 51 earthen dams, giving a density of artificial watering points of about one per 5,000 ha” (Pienaar *et al.*, 1998 *In: Brits, 1999*). Thus, over 96 % of the Kruger National Park, the average distance between permanent surface water is about 7 km (Pienaar *et al.*, 1998 *In: Brits, 1999; Brits, van Rooyen & van Rooyen, 2002*).

“Water-dependent herbivores are forced to congregate within walking distance from the watering points in the dry season” (Young, 1970 *In: Brits, 1999*). “This range has been estimated as 10 to 15 km in the Amboseli ecosystem (Western, 1975 *In: Brits, 1999*) and 12 to 16 km in the Kruger National Park” (Van der Schijff, 1957 *In: Brits, 1999*). A recent study in Kruger National Park concludes that grazers, including blue wildebeest, zebra, tsessebe, roan, sable, white rhino and buffalo that do not obtain adequate moisture from their food during the dry

season, tend to be positively associated with waterholes. Browsers such as kudu and giraffe are neutral in this relationship, and along with mixed feeders (excluding eland) are positively correlated with rivers. Similarly, water dependent elephant and waterbuck are more associated with rivers where it appears they are able to meet all their needs including habitat and forage. The major difference in nutrient rich basaltic soil areas compared to nutrient poor granitic soil areas with regard to the relationship between these species and water is that herbivores in the granitic areas must travel further from the water source to meet nutritional requirements. It also concludes that “grazers are therefore the feeding group that will be most affected by any changes in the water provision policy of the KNP” (Smit, Grant & Devereux, 2007).

“Most of the rangeland in the Kruger National Park is approximately 7 km from water and is therefore within reach of mobile water-dependent herbivores. Ecological carrying capacity for these animals is thus no longer affected by water availability, but is solely determined by the productivity of the vegetation” (Zambatis, 1985 *In:* Brits, 1999).

“Underutilized rangeland is an agricultural rather than a conservation concept. Although it is not desirable that underutilized rangeland dominates a conservation area, it should be viewed as habitat that should be preserved” (Collinson, 1983 *In:* Brits, 1999). “However, since few areas in the KNP are now farther than 10 km away from water, these underutilized habitats, with the herbivores and plants that are adapted to them, are now disappearing” (Thrash, 1993 *In:* Brits, 1999).

Likewise, the spacing and location of watering points is impacting wildlife distribution and speciation.

In the Kruger National Park, historically, roan antelope (*Hippotragus equinus*) have been almost entirely confined to the northern, drier half of the park with a

mean rainfall of 450-500 mm. The Kruger National Park population represents the southern margin of distribution for the roan species (Harrington, *et al.*, 1998).

Following the year-round provision of water in the northern portion of the park, populations of zebra and wildebeest numbers increased by 30%. Predators followed their prey species north with dire consequences for the roan (Harrington, *et al.*, 1998).

The population of roan had oscillated between 150-300 for about 60 years since the proclamation of the Kruger National Park (Grant, Davidson, Funston, & Pienaar, 2001; 2002). High rainfall (1986) and an abundance of palatable grasses followed by lower than average rainfall resulted in first an increase and then a decrease in roan numbers (Harrington, *et al.*, 1998; 1999; Grant, *et al.*, 2001; 2002) (Table 6.4):

The locally endangered roan antelope population of less than 50 roan was not viable according to genetics criteria (Harrington, *et al.*, 1998; 1999). Two other rare antelope species also showed population declines, the sable (*Hippotragus niger*) down to 85 by the end of the 1992 drought, five seen in 1997, three in 1998 and the Tsessebe (*Damaliscus lunatus*) down from 136 in 1992 to 35-40 by 1998 (Grant, 1999).

Table 6.4: Decline of roan antelope, Kruger National Park

Date	Roan Numbers
1977-1985	300
1986	450
1988-1991	150
1992	70
1993	44

Source: Harrington, *et al.* (1998) and Grant, *et al.* (2002) with permission, Koedoe.

Owen-Smith believes that both loss of food from over-grazing by zebra and wildebeest and increased lion populations were the key to the decline in roan populations (Owen-Smith, 1996). It is hypothesized that lions probably established territories around the artificial water points where prey concentrated. Roan coming to drink would face a greatly increased risk of predation (Harrington, *et al.*, 1998; 1999). The central cause for the ecological changes noted above is believed to be the provision of numerous artificial water points in the roan range, which attracted the influx of zebra and wildebeest during drought conditions in 1982/83, setting off this chain of events (Harrington, *et al.*, 1998; 1999). As noted earlier, bush encroachment appears to be another major factor impacting on roan and sable populations (see Section 6.1.4.4, Bush encroachment versus desertification), as well as decreasing rainfall (Owen-Smith & Ogutu, 2004 *In: Cumming, 2004 In: Child 2004*).

By March 1994, most of the windmills (12) in the prime roan habitat (Mills, Biggs, Funston, van der Walt, Viljoen & Viljoen, 1995) were closed on the Northern Basalt Plains (NBP) in an effort to decrease the zebra numbers (Grant, 1999). Zebra and wildebeest populations decreased due to the closing of the windmills and increased rainfall, allowing them to disperse, and in the case of the zebra, high predation rates. While the roan population appears to be in the process of recovery in the area where water points have been closed, it has been virtually eliminated in regions where water points remain (Funston, 1997; Harrington, *et al.*, 1998; 1999). This demonstrates that improperly placed and managed water points can pose a threat to biodiversity. The more common water-dependent species may increase at the expense of rare species, with the latter adversely affected by changed habitat conditions and predation pressure.

6.2.2 Boreholes and Wildlife, Klaserie Private Nature Reserve, South Africa

Similarly, in the 600 km² Klaserie Private Nature Reserve, a conservancy adjoining the central district of the Kruger National Park, the total biomass of ungulates was 40% greater than in the adjacent section of the Kruger National Park. After the 1982/83 drought, the ungulate biomass was 40% lower in the Klaserie Private Nature Reserve than in the Kruger National Park. In Klaserie, wildebeest, zebra, buffalo and waterbuck suffered 80-90% mortality, impala declined by 75%, four sables remained from a population of 50, and only four of 13 white rhinos survived. In neighboring Kruger, wildebeest and zebra declined by less than 10%, sable by 15%, waterbuck and buffalo by 30%, impala by 35% and white rhino were unaffected. The difference in herbivore mortality appears to be a result of differences in mean water point spacing: 2 km in Klaserie versus greater than 10 km (other references claim 7 km) in Kruger. In Klaserie, water points were so close together that no reserve grazing remained and animals starved to death (Owen-Smith, 1996).

6.2.3 Boreholes and Wildlife, Hwange National Park, Zimbabwe

In the Hwange National Park, Zimbabwe, the only perennial pools originally were in the Deka River floodplain along the northern boundary of the park. In 1962, Hwange's carrying capacity was 5,000 elephants (Thomson, 2003). About 50 boreholes were drilled to provide water to selected seasonal pans, resulting in a buildup of elephant, buffalo and zebra within the boundaries of this 14,000 km² park, mainly in the north and northeast tourist areas. Dams on seasonal rivers were also constructed. This resulted in 25% of the park being available to water-dependent herbivores during the dry season. By 1995, it was determined that even if the 22 critical boreholes could be maintained, this would supply only 20-40% of the water demand by elephant, which in turn was 80% of the total demand by all

wildlife (Owen-Smith, 1996). By 1991, the Hwange elephant population was estimated at 31,978. Unless more pumps could be maintained, the elephant population would need to be drastically reduced or the elephant would be forced out of the park, resulting in major human-elephant conflicts (Owen-Smith, 1996). Thomson (2003), former chief warden of Hwange, discusses the die-off of elephant, buffalo, etc., counting 778 head of dead game alone along one 20.7 km (8 mile) stretch of road leading to a remote dam during the 1962 drought. He goes on to conclude that a properly managed game reserve must be managed for a drought year, meaning that during normal and good rainfall/vegetation years, the number of animals being carried must be kept below the habitat carrying capacity for game during those “good years”, which will be much higher than the carrying capacity of drought years. This will “result in the habitats having a sufficient nutrient cushion (thus vegetation) to consistently absorb the effects of below-average-rainfall years” (Thomson, 2003). Today, Hwange is an ecological basket case. Hwange’s elephant population in 2000 was estimated at from 50-60,000, well above the 5,000 required to maintain biodiversity (Thomson, 2003). In 2000, Zimbabwe’s entire national park estate was estimated to have a dry season carrying capacity of 30,000 elephant, while the national population of approximately 84,000 elephant was about 45,000 beyond dry season carrying capacity (Machena & Chimuti, *pers. comm.*) (see Chapter 10, Section 10.4.5, Does CITES Help Southern African Elephant Conservation?).

6.2.4 Boreholes and Wildlife, Botswana

Eland moving westwards into the Kalahari Gemsbok Park, South Africa, during very dry conditions in 1985 suffered 35% mortality. This was ascribed to the provision of artificial water points at the end of the dry end of the population range where food availability was inadequate. Migration corridors may be needed

if these declines are to be reversed (Owen-Smith, 1996) (see Chapter 11, 11.7.7.1, Lomé Convention and subsidized beef in Botswana).

In the Chobe National Park and adjoining regions of northern Botswana, perennial water was until recently available only from the Chobe and Linyanti Rivers on the northern boundary and a few pans pumped erratically from boreholes. Extremely high elephant densities ($5-13/\text{km}^2$) developed along the Chobe and Linyanti riverfronts after seasonal pans ran dry. Because of concern about elephant impacts on riparian vegetation, numerous boreholes were drilled to supply water to the interior throughout the year (Owen-Smith, 1996). It would be interesting to know what, if any, unplanned adverse impacts occurred from this manipulation of nature, and if these boreholes have been actively managed to move elephant and other game around the Chobe area. Thomson (1997) describes the current conditions at Chobe,

“approximately 95% of the very narrow (but very important) riverine forest has already been destroyed and, devoid of vegetation cover, most of the topsoil on the steep bank has already washed away...the once rich Acacia/Combretum woodland habitats...on the broad alluvial planes immediately behind the riverine forest strip are virtually all gone...replaced by just 4 species of largely unpalatable woody scrub...away from the Chobe River the teak forest complexes, which grow...are in various stages of progressive, sometimes serious degradation. The syndrome started with too many elephant, over many years, opening up the top canopy of the forest...permits extra sunlight to penetrate the ground below – which promotes heavy grass growth where no grass grew before...so uncontrolled bushfires complete the cycle of destruction, scorching the under storey plants and tree saplings, and making conditions better for even more grass to grow. Now uncontrolled bush fires have become the most important agent in habitat change in the teak forest complexes of Chobe. In scientific terms, when one habitat modifying force (elephants) is replaced by another (fire) – as has happened at Chobe – it is said the ecological circumstances of the habitat have

'flipped'. The Chobe National Park, therefore, is now well advanced towards becoming a desert..."

Certainly, placing unmanaged boreholes into the interior away from the Chobe River facilitated, though it may not have stopped this process, given the out-of-balance elephant population. The estimated elephant population in northern Botswana's Chobe/Okavango Delta Complex was at 80,000 in 1998 (Gibson, Craig, Masogo, 1998), the management objective being 46,500 to 63,000 elephants for this area (DWNP, 1991) (see Chapter 10, Section 10.4.5, Does CITES Help Southern African Elephant Conservation?).

6.3 GUIDELINES FOR WATERING POINTS

Norman Owen-Smith has established a set of guidelines for water points in extensive protected areas. Though developed for wildlife, they can be equally applied to livestock. In both cases, by injecting year-round sources of water in rainy season dispersal areas, intensive management of available water will likely be obligatory as a means of controlling grazing pressure, by moving the grazers to other less-grazed areas. As demonstrated above, too often the active management of these perennial water supplies has been ignored, resulting in severe habitat degradation and in severe droughts and wildlife/livestock population crashes from inadequate food supplies.

Owen-Smith explains that populations of water-dependent herbivores typically show a dry season concentration near permanent water and wet season dispersal into areas removed from rivers or other perennial water sources. In most African wildlife systems, migratory species comprise the bulk of the large herbivore biomass. During the rainy season, they have traditionally dispersed into areas that are waterless during the dry season. This helps relieve the vegetation near

permanent water bodies (e.g., floodplains and other riparian habitat). Exceptions are waterbuck, impala, puku/kob, hartebeest and hippo, which tend to remain sedentary near permanent water holes (Owen-Smith, 1996). Traditional movement of nomadic pastoralists and their livestock followed similar movements, often side by side with the game.

Adding water points away from rivers or other perennial water sources reduces the extent of the wet season dispersal area relative to the dry season concentration area. In extreme circumstances, the entire area becomes accessible to water-dependent herbivores throughout the dry season. In such cases, plants lack a recovery period and areas of vegetation degradation coalesce, combining to form human-made deserts (Owen-Smith, 1996) and/or degraded bush encroached habitat.

Vegetation near water points needs to be relieved of herbivore grazing pressure during the wet season, so that plants can recover from severe grazing and trampling that they experience during the dry season. The distribution of water points determines where vegetation impacts occur and the seasonal duration of these impacts (Owen-Smith, 1996). Thus, both humans and their livestock, and wildlife react to these boreholes in similar ways and with similar impacts on the natural system. Owen-Smith (1996) suggests the following guidelines

1. Surface water availability forms the primary limitation on the distribution of large herbivore populations in semi-arid environments.
2. Species that predominate in biomass, notably elephant, buffalo, wildebeest and zebra are most affected by water distribution.
3. Some ungulate species can survive long periods without drinking, except during severe droughts.

4. Abundant water points favor common ungulates at the expense of rarer species through predator-mediated interactions, as well as vegetation impacts.
5. Excessively close spacing between water points increases starvation-induced mortality during droughts.
6. Temporary water sources alleviate pressures on vegetation near permanent water by reducing the period of concentration in these regions.
7. Because of seasonal water supplies, water dependent wildlife in Southern Africa may spend only about four months of the year near perennial water sources, meaning that the wet season grazing area could be twice that of the dry season. This is assuming that the productive potential of the two areas is similar.¹¹³
8. If the above is true, then the extent of the wet season range in area should be 2 times that of the dry season range to achieve equivalent grazing pressure.
9. It may be more acceptable to have more severe defoliation during the dry season when plants are dormant, than during the wet season period of growth. The critical period is early in the wet season when grasses are recovering from the previous season's defoliation.
10. For point sources such as boreholes, to achieve a 2:1 ratio of wet/dry season range, water points should be separated at least 3 times the potential travel distance of animals from water to grazing areas. Daily journeys of up to 5 km are typical for medium sized ungulates like

¹¹³ Note: In the Sahel, wildlife and livestock may spend more time than 4 months at perennial water sources, where rainy seasons are 4-5 months in duration and dry season floodplains are, or were extensive before massive hydropower dams that have drastically reduced floodplain ecosystems all over Africa, the traditional production systems for millions of rural Africans, their livestock and wildlife (e.g. See Chapter 7, Section 7.8.9.5, Waza Logone Floodplain, Cameroon, Impacts on Elephant and Livestock Populations, Waza National Park – where livestock remain on floodplains for six to eight months a year).

wildebeest and zebra, though buffalo and elephant can travel further. Thus, 15 km spacing is suggested between perennial water points.¹¹⁴

11. For linear water sources such as rivers, the minimal spacing needed is 6 times the daily travel distance to achieve the 2:1 ratio. Establishing perennial water sources between rivers should not be considered unless spacing between rivers exceeds 30 km. Stabilizing seasonal pans between rivers is not recommended if the distance between rivers is less than 60 km.

Factors such as uneven grazing pressure because of preferences for certain vegetation types and the possible active management of opening and closing water holes to move wildlife and or livestock around need to be considered.

6.4 CONCLUSION

Boreholes continue to be placed across Africa's savanna lands by well-meaning governments, donors, missionaries and other NGOs with little or no regard for the consequences Jasper Evans in Laikipia has proved that livestock can be managed and that wildlife can even be integrated onto lands with no dry season grazing through applying intensive management principles. As discussed in previous chapters, the lives of many nomadic pastoralists have forever changed in the 20th century through land compression to make way for European settlers and parks/hunting blocks, the population explosion, land tenure (e.g., centralization and privatization) and ill-placed boreholes. The net result has been the disruption of traditional management systems, the consequence of this being over-grazing that results in desertification or bush encroachment, depending on factors such as rainfall and intervention by man. When a drought occurs and pasture production worsens, massive die-offs occur, which to some degree probably always took

¹¹⁴ Similarly in KNP, Smit, *et al.* (2007) recommend at least 12 km between waterholes for similar reasons.

place during such times, but now may be worse since there is little reserve pasture. Large areas of Africa are already over-grazed, displacing perennial with less nutritious annual grasses.

What is missing? Processes that devolve ownership of land back to communities and re-empower them to manage their pasture lands on a communal basis make a lot of sense, just as they do for wildlife, fish and forests. However, pastoralists have been moved from extensive into intensive management systems, where boreholes must be opened and closed and/or cattle and wildlife actively/passively moved from watering point to watering point to avoid over-grazing in any one area, since with modern technology it is pasture, not water, that is limiting and this must be intensively managed. To be successful, pastoralists will need training to understand concepts such as 1) active management of boreholes, 2) concepts of dynamic carrying capacity linked to highly variable rainfall and 3) temporal/spatial relations to water in the non-equilibrium savanna systems of Sub-Saharan Africa. This will require integrating modern range management concepts into traditional pastoral management systems with flexible boundaries. A key to success appears to be selecting youth from these rural communities and sending them off to learn modern management principles [e.g., estimating carrying capacity (wet versus dry season), identifying and understanding the concept of increaser/decreaser plants, borehole management linked to habitat management, resource monitoring]. In many instances, it may require relearning traditional knowledge. Afterwards, they must be placed back into their community, where they will integrate this training into traditional management and control systems. With regards to wildlife, South Africa has made a number of mistakes and a number of corrections in terms of managing wildlife around watering points. There are many lessons to be learned by the rest of Africa from South Africa as regards developing relationships with parks and protected area management staff and academic institutions.
