Chapter 7

7.0 IMPACTS OF DAMS ON CONSERVATION AND DEVELOPMENT IN SUB-SAHARAN AFRICA

What is an African dam (Adams, 2000a)?

- “It is a dam which harms the livelihoods of river-dwellers; most African rivers have floodplains, and losing the annual flood below the dam is a disaster for traditional floodplain farming, fishing and grazing.
- It is a dam, which yields few compensatory benefits to peasant farmers; smallholders on irrigation schemes often find themselves unable to afford the extra costs of irrigated farming, and rent out or sell their land.
- It is a dam whose short-term gains to the national economy, through commercial farming of import-substitution crops or the production of electricity for industrial purposes, are elusive for want of a substantial entrepreneurial class.
- It is a dam built in countries where the institutions of civil society are weak, with no strong tradition of farmers’ organizations or non-violent protest” (Adams, 2000a).
- “It is a dam the only clear benefit of which, paid for dearly, is to shore up State prestige, so that dam critics in Africa do well to learn a verse from the Rubaiyat of Omar Khayyam: ‘When the King says it is midnight at noon, the wise man says behold the moon’ ” (McCully, 1996 *In:* Adams, 2000a).

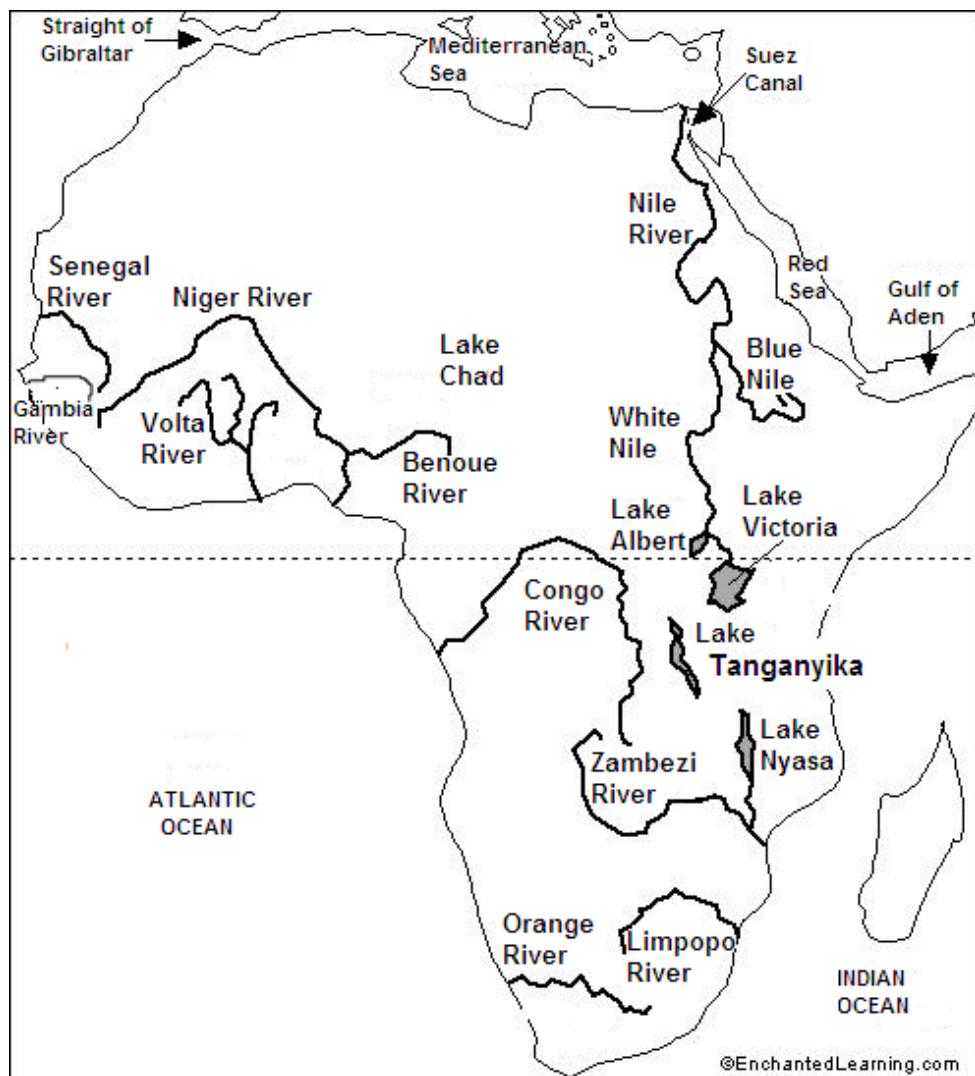

The net result of foreign aid and dams on the Senegal River “ ‘has enriched foreigners, entrenched corrupt states and alienated peasants’ ”. For the same amount of money, 200 small dams could have helped agriculture develop in 40,000 villages from Senegal to Chad (Dumont¹¹⁵ *In:* Rosenblum & Williamson, 1987).

¹¹⁵ René Dumont quoted from A Very Bad Finish

“It is clear that in the case of Cahora Bassa there was no serious attempt to ecologically optimize the dam prior to construction...furthermore, after dam closure, proposals put forward by the ecological assessment team were not implemented and there has been no regular monitoring of the dam’s downstream effects during its lifespan. As a result, Cahora Bassa has the dubious distinction of being the least studied and possibly least environmentally acceptable major dam project in Africa” (Bernacsek & Lopez 1984, Report to the U.N. Food Organization *In: Zambezi Valley News* 2003b).

According to the U.N. in 2000, worldwide, more than a billion people lacked access to clean drinking water and 2.5 billion had inadequate sanitation. Preventable water-borne diseases killed 10,000-20,000 children a day. Two billion people lacked access to electricity. More than half of all deaths from natural catastrophes were from natural floods. By 2050, there will be an additional 1.3-4.7 billion people, with many ecosystems already out of balance and unable to sustain the existing human populations (McCully, 2001).

While the African continent has only 11% of the runoff in the world (Figure 7.1), it has 13% of the human population, about 780 million people in 53 countries. As we enter the beginning of the 21st century, about 300 million people live in water-stressed countries, lacking sufficient water to meet basic human needs (see Chapter 13.11, AFRICA’S POTENTIAL WATER WARS). United Nations projections are that by 2025, 1.1 billion people or 75% of Africa’s population will be without adequate water. In Africa, the 60 international river basins shared by two or more countries make up 62% of the continent’s surface area, the highest percentage on any continent (Hitchcock, 2001 *In: Miller, Cioc & Showers, 2001*).

Modified from: Enchanted Learning (2007) with permission, Enchanted Learning.
Figure 7.1: Major rivers of Africa

With erratic rainfall, short rainy seasons and long dry seasons being typical of the majority of Africa's savanna lands and deserts, dams to store water and produce hydropower would seem to be the way to go, just as in the United States. The following provides an overview of dam development in Africa. It shares with the reader both the politics of dam building – much of which is tainted and destructive - and the environmental consequences of dams in Africa on the

people, their traditional production systems and the ecology. The big question is identifying the benefits versus the costs, especially to the environment, traditional food production systems and society, most of which have been ignored. The principal author's personal experiences are highlighted from having worked in river basin planning from 1977 to 1988 on both the Senegal and Gambia River Basin development schemes and peripherally in the Lake Chad Basin. The case study of the Senegal River is summed up in DeGeorges & Reilly (2006a; 2006b), while that of the Gambia River in DeGeorges & Reilly (2007).

It is hoped that this chapter will help change the West's approach to how it is dealing with the "Dark Continent", especially the politics and "plundering mentality" behind dam construction to date in Africa. At the same time, African decision makers must wake up to the reality of what dam building has done to their food production systems, their economies and their people. These monuments to modern technology have more often than not become legacies of failed governance and greed.

7.1 BIG DAM ERA IN THE WESTERN UNITED STATES

The first World Commission on Dams (WCD) report concluded that there were between 45,000 and 48,000 large dams in the world. All but 5,000 were built since 1950. A large dam is defined as measuring 15 meters or more in height from foundation to crest on the dam face – taller than a four-storey building. The world rate for dam commissioning peaked at 5,400/decade in the 1970s but has since fallen to just over 2,000. Peaks for dam commissioning were the 1960s in Europe and North America, 1970s for Asia and South America and the 1980s for Africa. It was estimated that during the 20th century, US\$ 2 trillion was spent on dams, the expenditure on large dams being between US\$ 32-46 billion/year in the 1990s.

On average, dams cost 30% more to build than projected. Benefits were found to be exaggerated (WCD, 2000; McCully, 2001):

- Of 63 large dams with hydropower, 55% generated less power than projected.
- The 58 irrigation dams assessed fell short of targets in area irrigated.
- Only 70% of irrigation area targets were met after five years and only 75% of the targets were met after 15 years.

The average cost overrun of the 81 large dam projects included in the WCD Cross-Check Survey was 56% (WCD, 2000).

In the dry western United States, in half a century, the Bureau of Reclamation alone built 355 dams with reservoirs, 254 diversion dams, 41,440 km (16,000 miles) of canals and 53 hydro plants (Ward, 2002). By 1962, nearly all of the major rivers of the United States – long reaches of the Mississippi, the Snake, the Columbia, the Illinois, the Missouri, the Sacramento, the Susquehanna, the Red, the Delaware, the Tennessee, the Apalachicola and the Savannah had been dredged, realigned, straight jacketed, rip rapped, diked, levied and stabilized for both flood control and navigation by the U.S. Army Corps of Engineers (Reisner, 1986). By the time it was all over, there were about 5,500 big dams and more than 2 million smaller ones in the USA (Ward, 2002), 99% built in the 20th century and just about all built by the Bureau and U.S. Army Corps of Engineers. Most of these dams, dikes and channels were subsidized, along with water, by the U.S. Government (Reisner, 1986) (see Chapter 12, Section 12.2.4.2, Agricultural subsidies, America's Agricultural Subsidies).

7.2 END OF THE BIG DAM ERA IN THE WEST

By the 1990s, environmental and social activists, as well as economics (construction costs as well as mitigative/opportunity costs of adverse social and environmental impacts) had all but ended the building of big dams in northern countries (McCully, 2001). Subsidized dams built by the U.S. Army Corps of Engineers and the U.S. Bureau of Reclamation for irrigation and hydropower had opened up the west of the United States, though many question their sustainability (Reisner, 1986). In America, President Ronald Regan in 1981 was the first to stop federal subsidies for dams, signing a bill to de-authorize 7 dams that would have cost the taxpayer US\$ 2 billion. By the time William (Bill) Jefferson Clinton took office in 1991, budget cuts and environmental laws all but killed big dams in America (McCully, 2001).

7.3 ECONOMIC RETURNS FROM BIG DAMS

On average, large dams are marginally economically viable. Multipurpose dams (e.g., more than one use such as irrigation, hydropower, navigation) are even less viable. The hidden long-term environmental and social costs when factored into costs and benefits make dams even less economically viable (McCully, 2001).

7.4 PEOPLE AFFECTED BY DAMS

As a result of the First International Meeting of People Affected by Dams, The Curitaba (Brazil) Declaration of 1997 called for an international independent commission to conduct a comprehensive review of large dams. The “Gland Agreement” of April 1997 laid the basic foundation for establishment of an independent “World Commission on Dams (WCD)”, first chaired by Kader Asmal, then the South African Minister of Water Affairs and Forestry (McCully, 2001).

In its Millennium Declaration, the General Assembly of the United Nations declared that the unsustainable exploitation of water resources would be stopped and that water management strategies to meet national, regional, and local needs, with a particular focus on equity and accessibility to the poor, would be introduced. Two and a half years later, the global landscape remained littered with examples of social and economic devastation due to the inappropriate management of freshwater resources and specifically, though not exclusively, the continuing development of large dams. The problem of access to water, food and energy is not a question of availability, but of access and distribution (McCully, 2001). For example, ESKOM South Africa produces 60% of Africa's electricity of which 46% is used for industry, 28% in transport, 10% in households, 9% in mining and 7% in agriculture. Yet over 70% of South Africa's population in 1989 was excluded from the network even though there was no shortage of electricity. Similarly, in South Africa, urban blacks consumed 10% of the electricity consumed by urban whites (Huntley, Siegfried & Sunter, 1989). It should be noted that South Africa is attempting to address these disparities without bankrupting the country (see Chapter 13, Section 13.14, NEPAD).

Interestingly enough, as this book goes to press, it should be noted that beginning in the second week of January 2008, failure to upgrade and build new power facilities, as recommended, is resulting in load shedding, with major adverse impacts on everything from mining, agriculture, retail sales, traffic, hospitals, trains, electricity available to neighboring countries as Zimbabwe, Zambia, Mozambique and Botswana supplied by South Africa, capital expansion in industry to foreign investment - a problem that will not be resolved before 2013. A major reason (excuse) given is that by 2008, the government had doubled "the numbers of people with access to electricity to 71% of the population, particularly in black townships and informal settlements" (McGreal, 2008). This could adversely impact the target of 6% economic growth by 2010 (BBC, 2008).

All over Sub-Saharan Africa, hydropower bypasses the majority of the rural and urban poor, serving a few elite in urban centers and industry. Power lines pass overhead of the millions whose lives have been forever altered, usually for the worse, by displacement due to reservoir inundation zones and floodplain losses. Many people feel that large dams fail to result in equitable access and distribution of these needs (McCully, 2001).

As the age of dam building in the West declined, dam construction and consulting companies linked to Western donors ventured into the tropics as a means of keeping these dam building/designing companies afloat (McCully, 2001).

7.5 FUNDING DAM BUILDING IN AFRICA

The World Bank is the largest financier of dams in the world; in many cases despite the obvious non-compliance with the institution's own policies. The UN Food and Agricultural Organization (FAO) and the United Nations Development Program (UNDP) have played a major role in promoting large dams and irrigation schemes. The U.S. Agency for International Development (USAID) and the Department for International Development (DFID), (in the past called the British Overseas Development Administration - ODA) are other important funders and planners of dams, often in partnership with other donors and in association with the private sector dam lobby. There is another worrying emerging trend whereby straightforward project lending is being substituted by a web of indirect financing that benefits domestic financial intermediaries and local hydropower utilities (McCully, 2001). Corruption and rule breaking, human rights abuses and environmental degradation have often accompanied the development and construction of the world's major dams (McCully, 2001).

“The World Bank owes a debt to the many millions of people whose lives it has destroyed through the financing and construction of large dams. The World Bank has lent more than US\$ 60 billion

for 538 large dams, including many of the world's largest and most controversial projects. Bank-funded dams have displaced more than 10 million people from their homes and land, caused severe environmental damage, and pushed borrowers further into debt. Despite its role in establishing and funding the World Commission on Dams (WCD), the World Bank has refused to implement the Commission's recommendations" (IRN, 2001a).

The World Bank's senior water advisor, South African John Briscoe, actively lobbied Southern governments to reject the findings of the WCD (2000) report (Bond, 2002).

7.5.1 Lesotho Highlands Water Project (LHWP)

Bond (2002), contends that the World Bank's recent funding of the Katse Dam, Africa's highest dam at 185 meters, as well as the Muela and the Mohale Dams, all completed by 2001, with another three to four dams¹¹⁶ in the planning phase as a part of the Lesotho Highlands Water Project (LHWP) (IUCN, 2002) to provide water for the Johannesburg-Pretoria area, "is a costly, corrupt, poorly-designed, badly-implemented, economically-damaging, ecologically-disastrous and distributionally-regressive megaproject" (Bond, 2002). The World Bank loaned \$150 million to the project to Phase IA (Katse and Muela Dams) in addition to loans from many other sources (IRN, 2000a).

In 1999, there was a court case in which 12 of the construction companies building the dam were charged with bribing the head of the project. At least six of the companies – from Switzerland, France, Italy and Germany – were linked to previous dam corruption scandals (IRN, 2000a). In 2002, the chief officer of the Lesotho Highlands Development Authority (LHDA) was sentenced to 18 years in jail (Bond, 2002; Transparency International, 2005). Over a nine-year period, he

¹¹⁶ Phase 2 pre-feasibility studies began in October 2005 (Engineering News, 2005), which includes the Mashai Dam scheduled for completion in 2007 (Engineering News, 2005) or 2008 (IRN, 2005).

received 46 bribes by multinational corporations for agreeing to “further their interest” (Bond, 2002).

“Following the conviction of LHDA’s CEO in June 2002, companies from Britain, Canada, France, Germany, Italy, South Africa and Switzerland were due to go on trial. The South African provincial government of Gauteng subsequently announced that, ‘if found guilty of bribery’, the companies concerned – which included major civil engineering groups in South Africa – would be disqualified from bidding for contracts in a proposed metropolitan railway” (Transparency International, 2003).

IRN (2005) lists the names of the companies and the alleged bribes. “The Lesotho High Court found in September 2002 that Acres International paid 681,316 Canadian dollars (US\$ 431,339) into Swiss bank accounts for the former head of the Lesotho Highlands Development Authority, Masupha Sole, between 1991 and 1998” (Mail & Guardian, 2005). People displaced by the LHWP dams are poorer because of so-called progress. Often compensation packages are late or not paid at all. “Each resettled family receives between 800 (US\$ 126) and 2,000 rand (US\$ 314) a year, and some say they have had to withdraw children from school as they are unable to feed themselves. Some say they no longer have land on which to bury their dead” (Lekhetho, 2005).

“Two of the Lesotho firms were involved in a Kenyan dam in the 1980s, which cost twice what it should but was approved because of bribes to the President and energy minister. Three firms were involved in the \$3 billion Yacyreta dam on the Paraguay-Argentina border, which had \$460 million in World Bank loans. In 1990 Argentine President Carlos Menem called the dam a ‘monument to corruption’. But it was built in the era of northern support for the military dictatorships of Latin America, and the World Bank turned a blind eye. Some of the money went into foreign bank accounts, while some went to the Argentine military. Some World Bank staff call Yacyreta ‘the dam that financed the Falklands war’ ” (Hanlon & Pettifor, 2002).

“According to one recent estimate, between US\$ 26 billion and US\$ 130 billion (5–25%) of the US\$ 525 billion lent by the World Bank since 1946 may have been misused or lost to corruption. The World Bank contests this estimate” (Transparency International, 2005). High levels of corruption in multinational development banks (MDB)-backed projects have been blamed on several factors, which include weaknesses in the MDBs themselves; institutional “pressure to lend”, with an emphasis on the quantity rather than the quality of projects, and weak internal controls at the banks, particularly in the supervision and auditing of projects (Transparency International, 2005). Bond (2002) believes that alternatives to dams in Lesotho would have been:

- Repairing faulty water distribution pipes in South Africa that result in the loss of 24-40% of the incoming water.
- Incentives to use water conservative toilets and showerheads.
- Pro rata tariffs as water consumption (industry, agriculture, middle and upper class in suburbs) goes up, to help subsidize water to the poor and to encourage water conservation.
- Convert farmers who use 50% of South Africa’s water to more efficient irrigation systems (e.g., drip irrigation) (see Chapter 5, Table 5.32: Water productivity gains when shifting from conventional surface irrigation to drip irrigation).

To cover the costs of these dams, the poor saw water tariffs increase by 30% and being unable to pay, many residents in the Gauteng townships of South Africa saw their water supplies cut by the municipalities. Thus, this “development” mainly benefited mines, industry and the middle-upper class suburbs to the detriment of the poor.

Thamae & Pottinger (2006) provide an excellent overview of the social and environmental consequences of the Lesotho Highlands Water Project. A recent study by Bosshard, Bruij, Horta, Lawrence and Welch (2003), “Gambling With Peoples Lives”, provides an overview of the World Bank’s debacles “High

Risk/High Reward Strategy”, a high risk for the environment and local people and great rewards for the consulting firms and construction companies from America and Europe. They are concerned that the Bank is returning to mega-projects such as big dams and that an “approval culture” in which appraisal becomes advocacy without adequate environmental and social analyses to assure minimum adverse impacts is becoming the norm. According to Transparency International (2005), “since 2003 the World Bank has started to re-prioritize infrastructure, and is set to increase its infrastructure lending from US\$ 5.4 billion to US\$ 7 billion by 2005”. On the positive side, the World Bank has begun the practice of debarring companies found guilty of fraud and corruption. The question that must be asked is, “How does this relate to misleading environmental assessments that lead/have led to ecologically and socially destructive projects, and will this be looked at retroactively”?

Dams do not have to be economically viable, since many of these loans to developing countries will be written off in five years. The dams are built and make a profit for international engineering and consulting firms, which do not bear the consequences if the objectives of the dams are not met or if the environmental and social impacts are negative. They return to their countries that much better off, often leaving behind a trail of destruction. The World Bank and other donor agency bureaucrats are promoted by moving large sums of money. Unlike private banks or commercial private sector investors, they have little incentive to assure that the outcomes are economically sustainable. In essence, foreign aid is political money (a small percentage of the developed world’s GNP/GNI, but a lot of money for the developing world), which is usually loaned to governments, who are rarely able to pay back their loans (see Chapter 11: “INDEPENDENCE”, “DEMOCRACY” AND FOREIGN AID DEPENDENCY, IMPACTS ON CONSERVATION AND DEVELOPMENT and Chapter 12, Section 12.5.3.1, Debt relief creates more debt).

Government officials in most borrowing countries use this dam money to feed political patronage systems and large procurement contracts may offer opportunities to siphon off funds. An important step that the World Bank must take to make good on its environmental and social claims is to release its staff from the pressure to move money quickly and reward them on the basis of the long-term beneficial impacts of their projects. Unfortunately, as the bank is expanding into the former communist countries and into the new field of so-called environmental projects, there has been little movement in this direction (Horta, 1994).

7.6 CONTRIBUTION OF DAMS TO FOOD PRODUCTION AND NUTRITION IN AFRICA

Of an estimated 270 million ha of irrigated land worldwide, about 30-40% is watered from dams. Dams contribute 12-16% of world food production, not the 33% purported by the dam industry. In Africa, when traditional “irrigation systems” such as recession agriculture on floodplains are accounted for, land under irrigation increases by 37%. FAO estimates that nearly 50% of the 5 million ha irrigated in Sub-Saharan Africa (see Chapter 5, Section 5.12.1.3, Irrigation potential) receives water from small- scale and traditional systems (McCully, 2001).

7.7 RIVER BASIN PLANNING AND DAMS IN AFRICA

The construction of the Kariba Dam on the Zambezi River in the 1950s ushered in an era of big dam building on the African continent. Most large dams in Africa were built on the U.S. Army Corps of Engineers’ “Integrated River Basin Planning Model”, epitomized by the creation of the Tennessee Valley Authority (TVA) in 1933 and the adoption of the TVA model by the United Nations in 1958

(Hitchcock, 2001 *In: Miller, et al.*, 2001; Ward, 2002). The idea was to approach river basin development in addressing the multifaceted development needs in an integrated manner. This was done by addressing the electricity, urban and rural development, navigation, agricultural, fishing, recreational and cultural needs of the people living within these river basins.

The problem is that many of these integrated river basin programs, based on big dams, became heavily politicized, either being show pieces in host-countries for politicians, big money for consulting firms and construction companies with large kick-backs to decision-makers, or part of the Cold War agenda of buying friends in the short-term regardless of the consequences to people or the environment. The result was that technical issues, especially both long-and short-term environmental and social consequences, were ignored and/or dealt with at a very superficial level. The idea was not a question of “will the dams be built”, but that they would be built at all costs regardless of how many human lives would be adversely impacted or how seriously traditional production systems (ecosystems) would be degraded. Mitigation was minimal if at all.

Very often, dams destroyed the lives of low-income people and often, “key benefits” such as electricity and irrigation benefited large corporations and wealthy households, but not the urban or rural poor (*Miller, et al.*, 2001).

It is believed that dams may be necessary, but technical as opposed to politicized planning and decision-making must be at the core of the selection process. This is necessary in order to assure that the most appropriate dam scenario is funded, which minimizes adverse short- and long-term impacts on the environment, permits adequate mitigation where critical to the survival of natural systems and the people who live from them, and which meets strategic development

objectives. Unfortunately, this has not been the history of dams in Sub-Saharan Africa to date.

Can this change; will Africa move forward? Is there a moral conscience in the 21st century, which will push the global community to help develop Africa as opposed to continually plundering its resources, making it vulnerable to economic manipulation to the benefit of the West?

The following (see Section 7.7.1, Planning at a Political Level, Section 7.7.2, Planning at the Technical Level Compromised by Political Agendas, Section 7.7.2.1, History of environmental planning in America and Section, 7.7.2.2, Africa is where the USA was prior to WWII) is taken from a presentation by the principal author at an IDEP¹¹⁷ conference on river basin development in Dakar, Senegal (DeGeorges, 1986). The principal author worked in the field of river basin planning in Africa from 1977 to 1988, on the development of the Senegal River, Gambia River and Lake Chad Basins. The basic premises are as true today as they were back in 1986.

7.7.1 Planning at a Political Level

Planning for agricultural development in river basins has been based primarily on an unrealistic goal of “food self-sufficiency”. Current and future population numbers have been projected. The quantity of food needed to feed these populations was estimated without much regard for the cost of achieving this goal or as to whether food security¹¹⁸ might be a more achievable goal. In turn, these

¹¹⁷ The United Nations African Institute for Economic Development and Planning, Headquartered in Dakar Senegal

¹¹⁸ Food Security in a global society assumes that a country uses its comparative economic and ecological advantage over the rest of the world to generate wealth, which could be food crops, but may also be timber, tourism, safari hunting, and transformation of natural resources (e.g., oil, timber, minerals, agricultural products) through industrialization. The idea is that if rice is cheaper to produce in Asia compared to West Africa, then West Africa will not try and take part in a losing

food projections were converted into the quantity of agricultural land needed to be placed in production over time in order to achieve this goal. Little effort was made to review the economic, social and environmental costs of attaining this production. Often the rate of programming this land into high tech irrigation production was unrealistic. The foundation stone of the pyramid needed to assure the success of such an undertaking, the rural community, was rarely consulted. The achievement of food self-sufficiency relied primarily on a very narrowed source of food production, primarily irrigated rice, in preference for better management of more diversified traditional food production systems (e.g., floodplain recession agriculture, rainfed agriculture, fisheries, forage, and wildlife) (DeGeorges, 1986; McCully, 2001).

Because emphasis was placed on one major agricultural system, the decision-makers tended to disregard those natural systems, which traditionally had been a major source of food, energy and economic livelihood for rural people. Many of these natural systems, already degraded because of drought and pressure from an ever-increasing human population and their associated domestic livestock, risked to be eliminated and/or highly degraded as a result of the level of political planning. In many instances, expensive and often uneconomical infrastructure (e.g., dams, large-scale irrigated perimeters) was attached to the goal of "food self-sufficiency".

Because rivers know no boundaries and because regional river basin development commissions have been established to coordinate development mandates of the commissions' member states (countries that have all or a portion of their political boundaries within a given river basin), these infrastructure projects often became much politicized. Instead of finding the most efficient, least expensive way of

competition that could and has destroyed much of its natural resource base/traditional production systems as on the Senegal River. At a minimum, irrigated rice should not be at the expense of traditional food production systems, but should compliment them.

development, which presented the smallest risk to the basin's residents and their renewable resource base, up until recently, most water resource development has been selected with a goal of modeling itself along the lines of agro-business style irrigated agriculture, as in the western United States and to a lesser degree in Europe. This has often been through inefficient government parastatals that have catered to the political elite rather than the small farmer.

Often financing and long-term recurrent costs of subsidizing this type of development by governments was overlooked. This often meant expensive dams for each country. Many developing countries are experiencing severe economic crises and are unable to pay back outstanding loans. Ever increasing human populations, many growing at 2-3% per year even with HIV/AIDS, combined with severe and unpredictable climatic conditions (e.g., continual cycles of drought in the Sahel) and ecosystems (e.g., savanna making up 70-75% of Sub-Saharan Africa – see Chapter 5) meant to sustainably support low population numbers (e.g., migratory pastoralism, slash and burn agriculture with long fallow periods lasting from a few years to as high as 20 years) are straining the already suffering economies and forcing donor agencies to take a closer look at how they are spending the little money they have for “development”.

7.7.2 Planning at the Technical Level Compromised by Political Agendas

Because river basin development organizations were established to carry out the political mandates of their member states, planning at a technical level has been met with resistance. They are often linked to international lending institutions and consulting/engineering firms with many kickbacks at all political levels, both nationally and internationally.

Planning units within river basin development organizations have been expected to plan within the realms of the political objectives established by the member states, whether these objectives are realistic or otherwise. Since normally a political solution has been selected, the planning unit is expected to justify this political decision and to study mitigative measures, where possible, to natural and human-made systems, which may be degraded or lost because of the proposed development project.

John Waterbury's (1979) *Hydropolitics of the Nile Valley* best sums up this problem:

“One of the gaps policy-makers have generally failed to bridge is also one that policy analysts have failed to bridge. It is the separation of the criteria for adoption of specific technologies from the criteria guiding the political and economic decision-making process. National policy-making elites are generally preoccupied with the latter, and they expect the technocrats to adapt their needs to the political decisions taken without regard to technological opportunity costs. Seldom do these two groups speak each other’s language. Seldom do they clearly perceive that close interaction of their two spheres, that a political decision may determine the adoption of a certain technology but once adopted that technology will then determine subsequent decisions...The result, both in terms of the decision-making process itself and the analysis of that process, has been a fragmented and incomplete picture in which many interrelationships are left unexplored. In this situation one cannot properly assess cause and effect, and that after all is what the exercise is all about. It may well be the case, and indeed in the conclusion we so argue, that policy-making groups and external creditors prefer an incomplete picture for then unanticipated errors can be written off to incomplete information and poorly defined responsibilities”.

The idea of planning at a technical level for river basin development was relatively new to Africa back in the 1970s and 80s. To a large degree, politics appears to continue taking precedent over technical concerns even in the 21st

century, (e.g., the Bujagali Dam at Jinja, Uganda - origin of the White Nile - Basalirwa, Babirye & Kidega 2000; IRN, 2000b); the Epupa Dam on the Cunene River (a wild and scenic river) along the Namibia/Angola border (IRN, 1999), the Namibian pipeline to extract water from the Okavango River upstream to supply the growing population in Windhoek, threatening the future of the Okavango Delta and the 6 meter high and 1 km wide Popa Falls Hydropower Plant less than 50 kilometers upstream from the Okavango Delta in Botswana (IRN, 2000c).

7.7.2.1 Africa is where the USA was prior to WWII

Africa, with the exception of South Africa, is where America was in the 1960s (highly degraded resources) and pre-WWII with regards to education. As in the United States in the 1960s, there is a growing awareness that the basis of Africa's economies and the life blood of its people, the natural environment, is being degraded as a result of both natural (drought – though this alone would be temporary) and human-made phenomena such as deforestation, over-grazing, mono-culture, decreased fallow periods, farming steep slopes, uncontrolled poorly thought out fires often late into the dry season and indiscriminate poaching of wildlife and fish stock.

Where the population of America organized to combat the degradation of their natural resource base, in Africa the population is not adequately organized, possibly fails to comprehend the global picture of what is happening and/or is alienated from centralized conservation policies (see Chapters 3-6, 9 and 11).

For the moment, the brunt of responding to and planning to overcome a continent-wide crisis falls on the shoulders of Africa's educated minority and the global community. The question is, "Do enough people care to make a difference"? The

power of public interest groups, such as the nascent Green Belt Movement of Kenya, will come later with a more educated populace.

7.7.3 Environmental Impact Assessment (EIA) Industry – No Hippocratic Oath

“The track record of EIA (Environmental Impact Assessments) for dams is dismal although it is not clear if there are few good examples or everyone writes about the bad ones” (Sadler, Verocai & Vanclay, 2000).

There are number of definitions for environmental assessments. For the purpose of this document, the following are discussed:

- **Environmental Impact Statements (EIS)** in which a “no action alternative” is compared to an often “politically preferred alternative”, along with a number of alternatives whose environmental, social and economical impacts are projected over a 20-50 year planning horizon and whose opportunity costs are determined (e.g., the additional cost required to achieve a given level of environmental or social protection such as controlled flooding).
- **Environmental Assessment (EA)** in which there is only one planned action, which is assessed for positive and negative environmental and social impacts. Only mitigation of negative impacts and enhancement of positive impacts is permitted. There is no comparison against a no action alternative or other development options, as often a decision has been made at a political level to go ahead regardless of the consequences.

Verocai (2000) states that most environmental assessments concerning dams in the early 1970s were as “EAs” undertaken at the request of International Finance

Institutions (IFIs), namely the World Bank, since the decision to build the dams had already been made, often in opposition to local and foreign environmentalists and scientific groups.

It is argued that although EIA (EA) procedures have improved,

“the effectiveness of EIA (EA) of dams in developing countries is that, in the great majority of cases, project proponents still consider the EIA (EA) process as a bureaucratic requirement to be fulfilled for project approval, isolated from the project planning and implementation cycle. EIA (EA) studies are often carried out after the decision on the site of the dam has been made and engineering studies and projects have been completed. The choice of site of a dam is usually determined by economic and engineering criteria, with little or no consideration for environmental (or social) issues. As a consequence, the opportunity is lost for considering dam site alternatives with less damaging environmental and social impacts” (Verocai, 2000).

There is little or no consultation with basin residents who will be directly or indirectly impacted by the dam (e.g., displaced within inundation zone, or farmers, herders, fishermen, etc. whose natural resources will be adversely impacted from loss of downstream flooding). Civil society is usually disorganized, unaware and often powerless in the face of what is happening until after the fact.

The two major case studies discussed in this chapter can be classified as follows. The Senegal River Basin environmental study was an EA, while the Gambia River Basin study started out as an EA and turned into an EIS as it became evident that the planned dam development scheme would be ecologically, socially and economically catastrophic to the basin.

The mandate for environmental planning must come from legislation passed by African countries. Since the 1970s, many countries have adopted various forms of environmental laws and have become signatories to many international environmental treaties. The problem today in river basin planning and in conservation and development is often not a lack of legislation but a lack of political will and the desire to make a quick profit. This can be on the part of national/local politicians or even international bodies/corporations. There are no innocents and many guilty parties in the environmental assessment and dam building fields for a number of reasons from Cold War politics in the past, to greed.

Until African countries are willing to apply proper environmental assessment techniques as part of their planning and decision-making process, real development will be put off for years. This will and is occurring, because in pursuit of achieving a quick-fix political solution to their problems, African countries and their people are being taken advantage of by the very political elites who run the countries, as well as expatriate and local entrepreneurs looking to make a quick profit with little regard for the consequences of their actions.

There is no Hippocratic Oath in the consulting industry. Environmental Impact Statements (EISs) and Environmental Impact Assessments/Environmental Assessments (EIAs/EAs) are often closely linked to Western Donors and consultants and consulting firms looking for their next contract. They feed the funding donor and host country politicians what they wish to hear; the justification of the development program and the spending of donor money. Since foreign aid is more political than developmental, there are no consequences for development failures, only for failure to move the money. After spending hundreds of thousands, if not millions of dollars, the last thing a donor wants is

for the “no action” alternative to come out as most desirable. This would make the donor bureaucrat look very foolish.

In turn, the dam lobby from the donor countries; engineering construction and consulting firms often heavily influence the donors. Often, there is no external review of these environmental assessments, which are self-serving with kickbacks to local politicians and even donor bureaucrats (McCully, 2001)

Thus, many consultants and consulting firms become highly paid scientific “prostitutes” in a capitalist system. Morality, ecosystems and people’s lives are important, as long as they do not get in the way of the bottom line - profits. McCully (2001) calls it the “EIA industry”.

The ultimate decision as to whether to go ahead with such a project is often more political than ecological or economical. In Sub-Saharan Africa, planning is top-down. There is no consultation of the local populations. Rather, these decisions are made by bureaucrats and politicians looking to further their careers and to benefit from lucrative local contracts and other kick-backs, and whose lives will be minimally impacted regardless as to whether the long-term consequences prove to be beneficial or not to local communities.

An often used argument is that the West destroyed much of its environment in developing and not until it reached a certain economic state did it begin to develop environmental conscientiousness. While this may be true, much of the Third World is rural and resource dependent, river arteries and their associated habitats being vital to their survival (McCully, 2001). These rural people cannot afford to degrade their natural resources deliberately, as their survival depends on their sustainable use.

If true mitigation of environmental and social consequences or irreversible unmitigative adverse impacts were costed into the cost/benefit analysis of many dams, they would never be built. This is the reason why as big dam building moves out of the public sector arena into the private sector arena, private investors are less than hungry to fund such projects (McCully, 2001). The only dams likely to be built on purely a private sector basis in the near future are small to medium-size run-of-river hydrodams. Large multipurpose dams such as the Aswan, which rarely fulfill all of their objectives, are even less appealing to investors than hydro-only dams.

High technology such as irrigation also has high initial costs such as construction, pumps, tractors, dams and tile fields where soil salinization is a problem, and high recurrent costs such as fertilizers, pesticides, spare parts, canal and perimeter maintenance. To date, these technologies have not proven that alone they are the solution to a cost-effective means of increasing food production and development (see Chapter 5, Section 5.12.1.3, Irrigation potential). They may compliment traditional production systems, but no one should be naïve or selfish enough to think that they can replace them with dams and irrigation.

The traditional production systems based on the renewable natural resource base are basically free and self-perpetuating if rationally exploited. They often provide a higher quality, wider variety and more nutritional source of food than irrigation that tends to be based on the mono-culture of rice. The roll of the modern day planner/technician should be to assure compatibility between the old and the new, between traditional and high tech. Natural systems management both compliments and becomes an alternative/escape in case either for technical, ecological or economic reasons, high tech proves unfeasible or takes longer to implement than is currently planned.

This is not to say that the status quo is acceptable. Africa's rural population is out-of-balance with the ability of its ecosystems to provide them with a sustainable livelihood, and remedies must be sought. However, the elimination of these traditional production systems through poorly thought out development plans and displacement/elimination of these traditional ecological and production systems by high technology that has yet to prove sustainable is also not the answer.

With this in mind, the following section looks at dams on African rivers, mistakes that were made, how planning might help find appropriate dam options, and how politics, nationally, regionally and internationally is often an impediment to proper planning.

7.7.4 Politics of Justifying Dams on the Senegal River

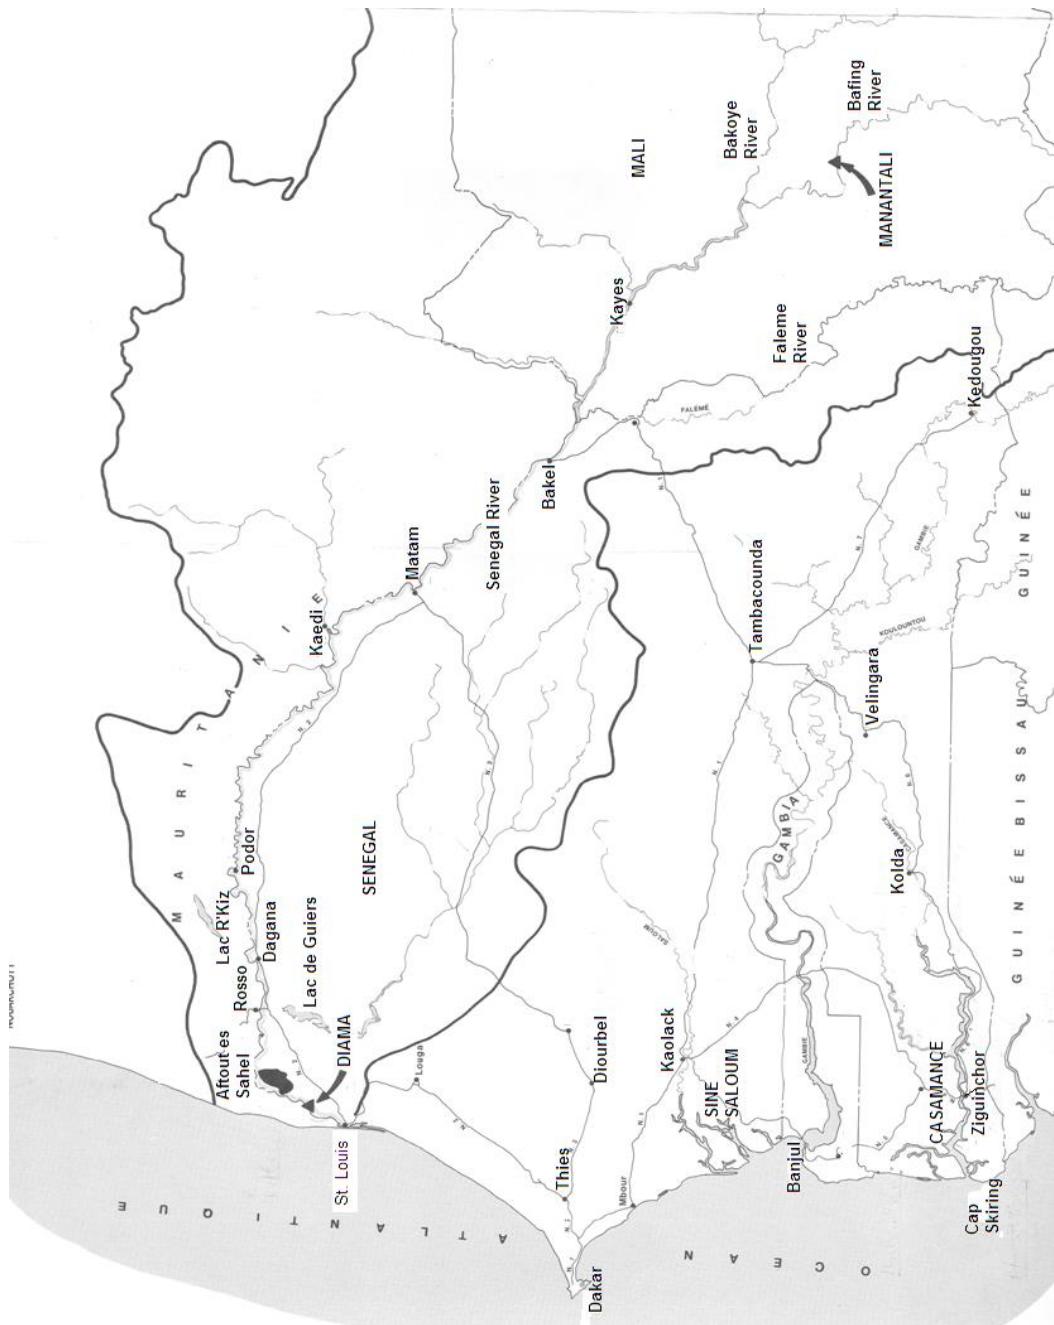

From 1977-1980, the principal author was brought in at the final stage of the Senegal River Basin Environmental Assessment awarded by USAID as a host country contract through the Senegal River Basin Development Organization/*Organisation pour la Mise en Valeur du Fleuve Sénégal* (OMVS) to the engineer consulting firm Gannett Fleming Corddry & Carpenter (GFCC).¹¹⁹ He first participated in putting together the water quality and fisheries reports (GFCC, 1979; 1980a) and then played a major role in putting together the final reports of the synthesis (GFCC, 1980b) and plan of action (GFCC, 1980c). From 1982-1988, he served as environmental advisor to the Gambia River Basin Development Organization/*Organisation pour la Mise en Valeur du Fleuve Gambie* (OMVG). The Senegal River is a floodplain ecosystem. The Gambia River relies to a lesser degree on floodplains and more on an extensive mangrove

¹¹⁹ Currently, Gannett Fleming Inc., 207 Senate Avenue, Camp Hill, Pennsylvania 17011, administration@gfnet.com, www.gfnet.com

ecosystem for its productivity. These river basins were the U.S. government's first large-scale environmental assessments in Africa. On the Senegal River, as the annual flood receded, hundreds of thousands of traditional farmers planted sorghum and millet, fishermen fished and nomadic pastoralists grazed their livestock along the river's floodplains.

The Senegal River Basin Environmental Assessment was a contract amounting to about US\$ 3.7 million (DeGeorges, 1980), sending multi-disciplinary teams of American engineers, agriculture, fishery, wildlife and public health specialists into the field to assess the impacts of planned dam development on the Senegal River. Hydrological modeling was undertaken to create artificial floods under various flow regimes once dams (Figure 7.2) were in place, as a means of maintaining freshwater and estuarine fishing, dry season forage and recession agriculture. The principal author was first brought in about two-thirds of the way through the study to work with the team assessing the impacts of the dams on the aquatic ecosystem, eventually being one of the key persons putting together the final project reports.

The Senegal River is the second longest river in West Africa, after the Niger River (4,200 km), with a length of 1,800 km and a watershed of 290,000 km². The upper basin in western Mali and Guinea-Conakry provides almost all of the river flow. No significant flows are added below the juncture with the Falémé River. Average annual precipitation is 2,000 mm in the headwaters (Guinean eco-climatic zone) and 250 mm in the northernmost area of the basin (Sahelian eco-climatic zone). The average annual discharge at Bakel, which measures accumulated flows from these headwaters, is 770 m³/sec. The average monthly maximum and minimum flows at Bakel are 3,500 m³/sec in September and 10 m³/sec in May (Gould, 1981).

Figure 7.2: Dams in the Senegal River Basin.

The rainy season in the upper watershed traditionally occurs between June and October and results in downstream flooding between July and November.

Traditionally, flooding occurred primarily downstream of Bakel in the Middle Valley, an alluvial plain 10-20 km wide and in the delta, the lower 200 km of the river (Gould, 1981). During the flood period, the main river channel exhibited typical riverine (lotic) characteristics from the beginning of the rains until February. During this period of active flow, isothermal conditions were approached due to the complete mixing of the water column by turbulence. Sediment entering from runoff in the upper watershed was transported downstream, greatly reducing the penetration of light into surface waters.

During the dry season, the river was navigable to Podor, 320 km upstream from the river mouth (Gould, 1981). From the onset of the dry season in November until the beginning of the rainy season in mid-July, the lower portion of the river became increasingly estuarine as the salt tongue pushed upstream from the ocean to Richard Toll and sometimes as far as Dar es Salaam, 218 km upstream from the mouth at Saint-Louis and at times to the Doué Marigot at Podor. These waters were greatly influenced by tidal action. In February, from Kaedi upstream, the river began to develop lentic (lacustrine or lake-like) conditions. This ponding effect reached a peak in late June and early July just before the rainy season (GFCC, 1979; 1980a).

In the 1970s, the valley was to be *le grenier du Sénégal*, Senegal's granary (Adams, 2000b). However, the Sahelian drought of the 1970s resulted in the creation of the Senegal River Basin Development Organization/*Organisation pour la Mise en Valeur du Fleuve Sénégal* (OMVS) on March 11, 1972 by the governments of Mali, Mauritania and Senegal in order to promote irrigation, power generation and navigation in the Senegal Valley. The purpose of the high dam at Manantali in Mali and the Diama anti-salinity barrage – located 27 km upstream from the river's mouth between Senegal and Mauritania - was to

provide enough water to achieve the following development objectives (GFCC, 1980b):

- Irrigate 255,000 ha, according to GFCC (1980b); 185,000 ha in Senegal, 62,000 ha in Mauritania and 8,000 ha in Mali (GFCC, 1980d). Others use the figure of 355,000 ha (Bosshard, 1999) and even 420,000 ha (see Chapter 5, Section 5.12.1.3, Irrigation Potential). This latter figure is close to an average flood of 459,000-549,000 ha, as calculated by GFCC (1980b; 1980d);
- Produce hydropower (800 GWh [Gigawatt hours]/year)¹²⁰ (GFCC, 1980b);
- Make the river navigable all year round between Saint Louis at the river mouth and Ambibédi in Mali;
- Supply freshwater for *Lac de Guiers*, which is a source of the freshwater supply for Dakar, the capital of Senegal (Diop, Nakamura, Smith & Khaka, 2000);
- Availability of surface water for annual recharge of *Lac R'Kiz* and Aftout es Sahel in Mauritania; and
- A year-round flow of 100 m³/second in excess of irrigation and other requirements to provide water depths needed for navigation (GFCC, 1980b).

According to the GFCC (1980b),

“In July 1974 at the prospective donors meeting held at OMVS in Nouakchott, Mauritania, the U.S. Agency for International Development (USAID) proposed that a detailed evaluation be undertaken to determine the potential effects of the integrated development plan on the environment of the River Basin and its population. USAID felt that a balanced approach between the considerations of economic development and the protection of the environment must be considered by all potential donors to insure

¹²⁰ A kilowatt hour (KWh) is equal to a 1,000 watt light bulb for one hour. One GWh equals 1 million Kwh

that maximum long-range benefits would be derived from the OMVS development program. The early identification of adverse impacts would permit the application of corrective measures prior to the development of environmental damage... This proposal was supported by other prospective donors as well as the OMVS, who were anxious to avoid problems that have arisen in similar water resource projects in tropical and sub-tropical areas of the world”.

The objectives of the GFCC environmental assessment were (GFCC, 1980b):

- To evaluate the interrelated effects on the environment caused by development in the Senegal River Basin;
- To optimize the long-term benefits by insuring the environmental and social factors have been identified and included in the cost-benefit analysis of individual projects; and
- To provide the OMVS riparian states with a plan of action for formulating programs and projects that mitigate adverse environmental effects and capitalize on those deemed beneficial.

For the purpose of this environmental assessment, the Senegal River Basin was divided into (Figure 7.2):

- a) Lower Valley (Delta), which includes the zones of Dagana and Rosso to the river mouth.
- b) Middle Valley (*Moyenne Vallee*), which includes the zones of Podor, Matam, Bakel, Boghe, Kaedi, Selibabi and Kayes.
- c) Upper Valley (*Haute Vallee*), which includes the zone of Bafoulabe – basically upstream of Kayes.

In the Lower Valley, the term “Lower Delta” is used to discuss the estuary below the Diama Dam face 27 km upstream of the Senegal River mouth and the “Upper

Delta”, which could be described as from the Diama Dam face to the upper limit of the salt tongue which in the extreme went as far upstream as the Doué *Marigot* at Podor, 320 km upstream from the river’s mouth. The Manantali Dam is located in the Upper Valley in Mali, about 1,200 km upstream from the river mouth on the Bafing River, the main tributary of the Senegal River, which supplies approximately 50% of the annual flow of the Senegal River (GFCC, 1980b). Adams (2000b) estimates the Bafing to provide 60% of the annual flow of the Senegal River.

As will be seen, the GFCC environmental assessment, funded by USAID at about US\$ 3.5 million, did not lie about adverse impacts, but perpetuated the myth that pumped irrigation of rice and other agricultural products would offset the losses of the diverse array of traditional food production (e.g., estuarine and freshwater floodplain fisheries, recession agriculture, dry season forage for livestock and some wild foods) from modification of the natural systems by dams and irrigation. This was even though many within the organization, especially the project agronomist¹²¹ knew that pumped irrigation was neither economically nor ecologically viable. Salinization of the soils from irrigation and high saline groundwater tables would make the cost of pumped irrigation very high, if sustainable, making it cheaper to import rice from Thailand than to grow it in Senegal. Both USAID and GFCC staff were aware of this problem, but kept the myth going, thus justifying the construction of the dams and being as responsible as anyone for the catastrophe that followed (DeGeorges, 1987a). Thus, traditional production systems were eliminated, while the high technology introduced was not cost-effective, but international and local consulting firms, as well as some politicians became richer and individual careers advanced.

¹²¹ Walter Firestone, an old FAO hand in Africa

Diama was completed in 1986 and Manantali in 1988; both dams were inaugurated in 1992. Thus, they were built during a period when irrigated farming encountered increased difficulties: massive unpaid debts, an ecological disaster in the making in the delta (e.g., soil salinization on a massive scale) and irrigation schemes lying abandoned in the valley (Adams, 2000b).

7.7.4.1 Construction costs

Construction of the Diama began in 1981 and ended in 1986, while the Manantali construction went from 1982-1988, both being inaugurated in 1992 (Adams, 2000a). On the Senegal River, it is estimated that US\$ 784 million (98%) of the US\$ 800 million spent on the design and construction of the Diama and Manantali Dams went to expatriate firms. The loans to pay the dams came mostly from Arab Gulf states wishing to expand their influence in this Muslim area, France and Germany (McCully, 2001).

Construction of the Manantali Dam cost about \$500 million (Bossard, 1999). Adams (2000a) estimates that the cost of the two dams was US\$ 800 million. Funding was provided by several Arab governments, the Islamic banks and the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD), Italy, the French CFD, the German KfW (German Development Bank), the Canadian International Development Agency (CIDA) and the European Union (EU). The civil works contracts for the Manantali Dam were awarded to Ed. ZUBLIN (Germany) and Losinger (Switzerland). The World Bank declined to support the Manantali Dam, which it did not consider a reasonable investment, and stopped all funding to OMVS in 1979. USAID also declined to support the construction of the dam, but provided financial and technical assistance for environmental assessments that justified the dams and development scheme, and resettlement. This in turn provided justification for other donors to give funding

(Bosshard, 1999). The French constructed the Diamal Anti-Salinity Barrage (Dam).

The only beneficiaries were the American, French and German consulting and construction firms, along with some of the bureaucratic elite who were able to skim money. The USAID funded EA was a host country contract controlled by the OMVS. An audit by the firm, Arthur, Anderson & Gaye, which the principal author was involved in, showed money from the EA disappearing into the OMVS that could not be accounted for. There was rather good evidence, though never outright proof, that one of the OMVS officials was using project vehicles and money to run a taxi service. Soon after, USAID stopped “host country contracts” running their money through American consulting firms and NGOs.

7.7.4.2 Hydropower

The Manantali Dam was to produce 800 GWh per year of hydropower (GFCC, 1980b). In June 1997, despite serious environmental and socio-economic concerns raised by a host of critics, the World Bank approved a US\$ 38 million loan to help finance installation and operation of the dam's turbines. As noted, the bank was not a lender for the original construction of the dam. The plan was to increase power output at the expense of other uses, with hydropower having first priority when reservoir levels fell (Pottinger, 1997). Electricity from the Manantali would supply 52% of production to Mali, 15% to Mauritania and 33% to Senegal (Baxter, 2001) and was to be operated and maintained by ESKOM Enterprises of South Africa, which has a 15 year contract (Bond, 2002). Many are concerned that this spells the end of water being made available for controlled flooding to maintain ecological and traditional food production systems (see Section 7.10.7.1, Senegal River).

7.7.4.3 Navigation costs

One of the main purposes of the Manantali Dam was to regulate the Senegal River to allow barges to carry bauxite and iron 900 km from Kayes, Mali, to the sea. The cost of dredging and construction of over US\$ 400 million makes the likelihood of this ever happening very small (McCully, 2001).

7.7.4.4 Conclusion

As the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD) points out, “social disparities and malnutrition” have appeared or increased among the affected people, and the rich Senegal Valley has become the poorest [area] in all three countries (Bosshard, 1999).

“The tragedy of the Manantali project did not come as a surprise. Independent observers predicted many of the negative impacts, which have materialized in the meantime. The World Bank consciously declined to get involved in the funding of the dam (though it did fund the hydropower), and temporarily stopped funding OMVS in 1979 as a consequence of the ill-conceived project. Eugene Brantly and Karen Ramsey, environmental health experts of USAID, conclude that ‘the financing consortium could have required changes in the project's design but did not’, because the funders ‘were eager to participate in the project’ ” (Bosshard, 1999).

Lessons regarding financial institutions can be learned from the experience of the Manantali and Diama Dams:

- Development aid and construction is big business and during the politics of the Cold War, capitalism had only one moral value (and maybe still does), “the bottom line – profits”, as well as the next contract. The

philosophy of many firms was “give them as little as possible, just enough to meet their demands, thereby maximizing profits”.

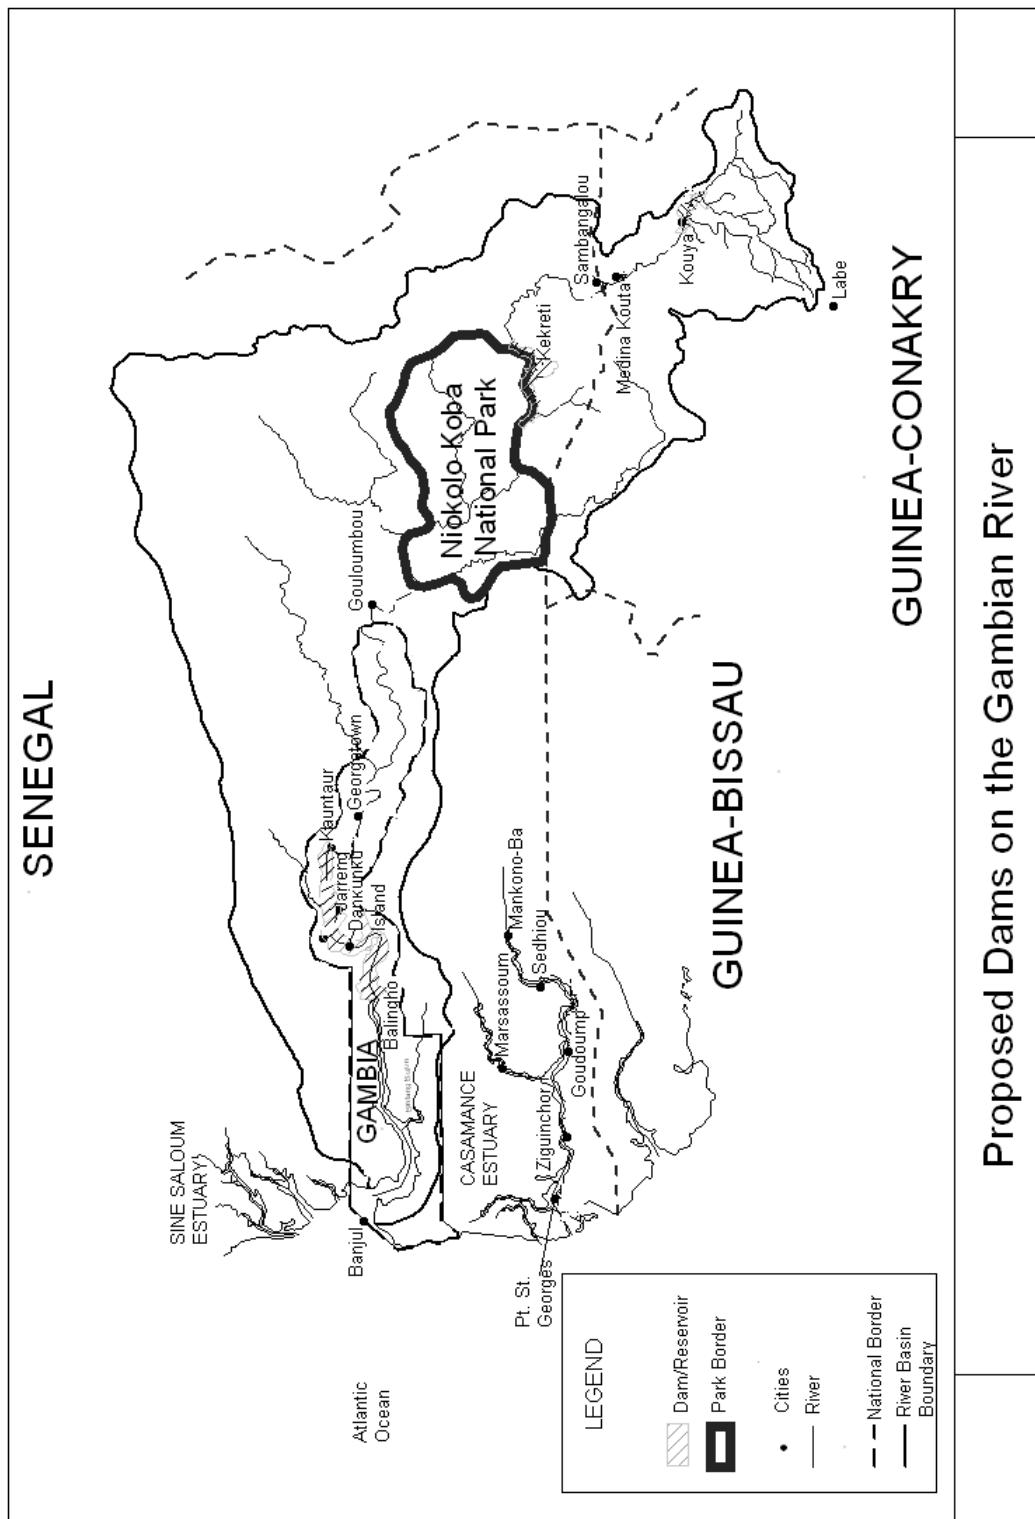

- Because development and construction takes place on foreign soils, the “Trojan horses” left behind, whether they work or not, are the problems of the host countries, especially the rural poor, but not of the foreign aid agencies, consultant or construction firms.
- In fact, profit can be made in studying the ecological and human tragedies post facto, and in trying to “do the impossible to fix Mother Nature after you have broken her” - with mitigative measures such as artificial floods, artificial estuaries, fish culture, etc., or relocating inundation victims, often to areas in which their lives are worse than before with poorer soils and living conditions.

The new Manantali hydropower project indicates that financial institutions, including the World Bank, have not yet internalized the negative lessons of past experiences.

One might ask, “What is worse, a plane crashing into the Twin Trade Towers of New York, killing about 3,000 people on 9/11/2001, or the lives of 500-800,000 people being destroyed as a net result of the Manantali/Diamma Dams, purely for profit motives”? Yet those responsible for this human and ecological tragedy and many more across the subcontinent have never been held accountable!

7.7.5 Politics of Proposed Dams on the Gambia River

Beginning in the early 1980s, the next river to be developed after the Senegal was the Gambia River Basin (GRB). German and English consulting firms located the Balingho anti-salinity barrage/bridge 128-134 km upstream from the river mouth and the Kekreti Dam about 790 km upstream from the mouth (Figure 7.3).

Source: Authors

Figure 7.3: Dams in the Gambia River Basin.

As on the Senegal River, American teams undertook the environmental assessment, only this time they did not try and justify the politically preferred alternative, possibly due to a large number of them originating from academic institutions (University of Michigan and Michigan State University) and thus refusing to be involved in the dirty politics of dam building. The well-known dam building company Harza¹²² had a minor role to play in this environmental assessment.

The principal author was hired on contract between 1982 and 1988 as the environmental advisor to the Gambia River Basin Development Organization/*Organisation pour la Mise en Valeur du Fleuve Gambie* (OMVG), the coordinating river basin planning body for the environmental study and development of the basin. He had a Senegalese counterpart, Idrissa Samba,¹²³ just retired from the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD). Member states included the Gambia, Senegal and Guinea-Conakry, with Guinea-Bissau eventually joining, mainly for political purposes, since none of its territory fell within the Gambia River Basin (GRB).

The Gambia River Basin is a semi-arid region of West Africa located between latitudes 11°.20' and 14°.45' and longitudes 11°.15' and 16°.30' West. The basin is limited by the Fouta Djallon Mountains in the south, the Senegal River Basin in the east, the Atlantic Ocean in the west and the arid Ferlo region of Senegal in the north. The basin covers 77,100 km², about 25% the size of the neighboring Senegal River Basin of 290,000 km². It lies in three different countries:

¹²³ Hajj Idrissa SAMBA, Environmentalist; African Development Bank/*Banque Africaine de Developpement* (ADB/BAD)/ONIN.0, Temporary Tunis Location ATR, BP 323-1002 Tunis, Belvedaire; Tunis Tel. +216-71102657; Fax: +216-71333680 Email: I.Samba@afdb.org or Idisamba@yahoo.com. Retired end of 2007.

- Guinea-Conakry: 15% of basin.
- Senegal: 71% of basin.
- The Gambia: 14% of basin.

The Gambia River extends a total of 1,180 km. Based on the hydrology of the basin, it is broken up into the:

- Estuarine Basin from the mouth in the Gambia to Gouloumbou, Senegal (Figure 7.3), the end of tidal influence, a stretch of 530 km in length covering 36,000 km². Within this basin is the Lower Freshwater River Zone from kilometer 250 upstream from the mouth at Kuntaur to Gouloumbou at km 530, the major zone of pumped irrigation potential.
- Continental Basin which is upstream from Gouloumbou, a stretch of 240 km long to the source a few kilometers from Labé in Guinea-Conakry at an altitude of 1,125 meters IGN (Institut Géographique National), covering 41,000 km².

The source of the Gambia River, the Fouta Djallon Mountains in Guinea-Conakry is often called the *Château d'Eau* or “West Africa’s water reservoir” since this is the primary source of water for major rivers such as the Gambia, Senegal and Niger (N’Diaye, 1987).

The major development objectives of the OMVG and its member states at the time of this analysis were (OMVG, 1985a *In: Samba & DeGeorges, 1987a*):

- Achieve self-sufficiency in food in the sub-region.
- Increase rural income and insure a more equitable distribution of income in the sub-region.
- Promote industrial development.

The role of planning was to take into account these development goals and eventually to provide decision-makers the prospects of achieving these goals within a reasonable time frame. It should allow the decision-maker to evaluate the trade-offs of achieving various development goals by different development scenarios and the “opportunity costs” of achieving development goals while protecting key natural resources, such as estuarine and floodplain fisheries and/or tidal/swamp culture, and still achieving goals of increased food production from irrigation. Originally, this was to be an EA of a two dam scenario, the Balingho Anti-Salinity Barrage and the Kekreti High Dam but because of concern over potential catastrophic environmental and social impacts, an EIS with multiple scenarios was undertaken. Development options included:

- 1) **Kekreti/Kouya/Balingho.** The high dams of Kekreti and Kouya, and the Balingho Anti-Salinity Barrage all on the main channel of the Gambia River with emphasis on irrigation.
- 2) **Politically preferred scenario: Kekreti High Dam/Balingho Anti-Salinity Barrage.** The scenario furthest along with regard to engineering feasibility studies, with emphasis on irrigation.
- 3) **Kekreti High Dam only** with irrigation in Senegal and the Gambia, and improved swamp rice culture in the Gambia.
- 4) **Kekreti High Dam only** with irrigation only in Senegal and improved swamp rice culture in the Gambia.
- 5) **The Sambangalou or Medina Kouta High Dams** on the main channel of the Gambia River with irrigation in Senegal and the Gambia along with improved swamp rice culture in the Gambia. The Sambangalou Dam face is in Senegal but the reservoir would continue into Guinea-Conakry. The Medina Kouta Dam face and reservoir would be entirely within Guinea-Conakry, but would not have as much power potential.

- 6) The High Dam of Kouya** in Guinea-Conakry on the Gambia River with irrigated agriculture in Guinea-Conakry, Senegal and the Gambia and improved swamp rice culture in the Gambia.
- 7) The High Dam of Kouya** with irrigation in Guinea-Conakry and Senegal and improved swamp rice culture only in the Gambia.
- 8) Non-structural – mini-barrages** mainly for small-scale irrigation.
- 9) No action**

The Balingho “bridge barrage”, conveniently located at the ferry crossing, would be dual purpose: control saline intrusion to allow upstream irrigation and provide rapid deployment of Senegalese military forces to put down if necessary and de-enclave the unruly Casamance, Senegal territory lying south of the Gambia. Its population, predominantly **Jola (Diola)**, continually push for secession (see Chapter 3, Section 3.1.4.1, Francophone colonial Africa). The problem is that the risks were very high in that the Balingho would have wiped out a major mangrove ecosystem and related fisheries and would have destroyed a minimum of 12,930 ha of tidal rice operated by about 43,000 women and an additional +40,000 ha of potential tidally irrigated rice in favor of pumped irrigated rice, which was not economically viable (see Sections 7.9.1.2, Gambia River and 7.9.7.2, Gambia River). There would have also been major health implications with an increase in water borne diseases.

A dam engineer, basing his decision on a base map and finding two promontories along which the dam face could be constructed, selected the dam site of the Kekreti. This just happened to be in a World Heritage Site, the Niokolo Koba National Park, and the construction of the dam was projected to have a major adverse impact on the movement of game. It was also along a major fault line. During the study, an earthquake centered a short distance north in the Fouta Djallon Mountains of Guinea-Conakry and measuring 6.3 on the Richter Scale

along this fault (Le Soleil, 1983 *In:* DeGeorges & Samba, 1987a), killed 200 and injured 300 people.

After spending approximately US\$ 16 million between 1983 and 1985 using multi-disciplinary teams of the University of Michigan/Michigan State and host country counterpart teams (Senegal, Guinea-Conakry, Guinea-Bissau and the Gambia), it was concluded that the best dam option would be a high dam in the Fouta Djallon Mountains (including the Sambangalou) to control river flow and saltwater intrusion, as well as provide hydropower. Analyses by both University of Michigan and the OMVG staff (Samba & DeGeorges, 1987a) indicated that any alternative with the Balingho would have grave consequences, both ecologically and socially. Mini-barrages for irrigation might also be useful. At the time, Senegal for security reasons did not want Guinea-Conakry controlling their water supply and rejected the idea of a high dam across their border.

One decision opted for during this study was that U.S. members be teamed up with counterparts from the host countries. This proposal was first resisted by USAID but then accepted at a meeting on the insistence by the then director of environment from the Gambia.¹²⁴ About 3-4 years later at an OMVG meeting of member states over the results of the Michigan Study, which put into question the economic and ecological viability of the Balingho Anti-Salinity Bridge Barrage, a Gambian technician¹²⁵ with the Department of Fisheries said, “I was in the field, helped work up the results in the laboratory and conducted the analysis. The results of the Michigan River Resources Team are as much mine as theirs, and I support their conclusions 100%”. The then high commissioner, Malick John, was shell shocked that one of his countrymen would make such a statement in front of politicians, putting his career on the line. This may have been one of the most

¹²⁴ Omar Fye, currently Senior Environmental Specialist, Africa Region, World Bank, Tanzania Resident Mission, Dar es Salaam, Tanzania, Tel: 255-22-211-4575, Cell: 255-744-440-412, Sfye@worldbank.org.

rewarding moments in the principal author's period of stay with the OMVG – seeing how knowledge is power, and how giving “the little guy” information forces the often corrupt and self-serving politicians in line.

Of course, this did not stop USAID. The U.S. government (USAID) brought in a “Beltway Bandit”¹²⁶ from Washington, D.C. – RONCO Consulting Corporation, which was willing to say that the best and brightest from the USA and their counterparts were wrong and that international donors should return to the politically preferred alternative of the Balingho and Kekreti Dams. RONCO’s website¹²⁷, promotes the firm as a specialist in “humanitarian” mine clearance, security services, environmental remediation and post-conflict operations, providing “public and private sector clients with advisory, training, implementation, and management assistance”. RONCO’s current president, Stephen Edelmann managed the USAID/OMVG contract. In the book Mercenaries (O’Brien, 2000 *In:* Musah & Fayemi, 2000), RONCO is listed among Private Military Companies/Contractors (PMCs) and one of the first PMCs brought in by Rwanda after the genocide for demining expertise and technology, as well as limited training to Rwandan forces, providing similar expertise in Mozambique from 1996-1997. RONCO appears to have received its baptism serving as a “soldier of fortune” to the “highest bidder”, in the case of dams on the Gambia River to USAID/Senegal¹²⁸ who oversaw this project. Madsen (1999) gives further insight implying that RONCO served as a cover for direct U.S. invasion of both Rwanda and the DRC (see Chapter 13, Section 13.7.1.1, Legitimization of private military companies/contractors (PMCs) by western governments and international bodies).

¹²⁶ Alludes to the 495 beltway/road that circles the nation’s capital, allowing ease of access from Maryland and Virginia suburbs where the majority of government workers and their “private sector” contractors reside.

¹²⁷ RONCO Consulting Corporation, 2301 M Street, N.W., Suite 400, Washington, DC 20037, www.roncoconsulting.com/index.html

¹²⁸ Sarah Jane Littlefield - Director and Vito Stagliano

In the principal author's departing internal debriefing memorandum to USAID (DeGeorges, 1987a), it was stated that after RONCO had at first been requested to incorporate the principal author and his counterpart's report (Samba & DeGeorges, 1987a; 1987b), RONCO now appeared to be bypassing the institutionalization of the planning process to "hastily produce a 'Model Integrated Planning Document' (by RONCO) in which the OMVG had virtually no participation". Sensitive documents were being withheld from distribution, and it appeared that "attempts are being made by unscrupulous consultants to discredit the 16 million dollar University of Michigan study, where we sent over 'our best and brightest' to address a number of very complex and complicated issues". The memo went on to remind USAID that the need to analyze basin-wide alternatives

"as required by Federal law (National Environmental Policy Act – NEPA), by requirements in the project paper and amendment, and in his contract - has been eliminated. In its place basically a one scenario alternative, which is the politically preferred alternative of Kekreti/Balingho scenario was substituted, which all donors had refused to fund over the last 10 years. The situation was reminiscent of 1982 when the project was considered to be political, not technical in nature and advisors were forced to bias their analysis".

When the principal author first arrived in Senegal in 1982, suggesting that a no-action alternative projected along a 40 year planning horizon be compared against not only the politically preferred alternative but other dam options, he was reminded¹²⁹ that he was there to mitigate only the Balingho/Kekreti scenario – basically an EA, regardless of his concerns for the impacts of the Balingho barrage on a major mangrove ecosystem, associated fisheries and upstream tidally irrigated rice - or he would be removed from the project. It was not until the

¹²⁹ By USAID Project Manager, Louis Lucke

entire “University of Michigan” team refused to accept a one-scenario alternative because of the potential environmental and social consequences that USAID and the OMVG relented. The study eventually recommended against the Balingho Anti-Salinity Barrage due to the potential for adverse long-term impacts on both the natural and human-made environment that could not be mitigated. Eventually, the principal author was requested by the OMVG high commissioner¹³⁰ to change what he and others had written, namely that there was a strong risk of the Balingho wiping out a large portion of the mangroves and associated fisheries, to that there would be a minimal impact on these resources. The principal author refused as a technician explaining that this was his best professional judgment based on his life’s experiences and the findings by the University of Michigan Team. The principal author explained that the role of the high commissioner, who dealt at a political level, was to take this technical advice and work within the political realms of the member states but not to falsify data. The principal author was thanked. Eventually, the UNDP advisor¹³¹ to the OMVG was convinced to make the changes. With the help of USAID personal services contractor and acting project manager¹³², the UNDP advisor was eventually seconded to the Manantali Dam site on the Senegal River, addressing the inundation victim resettlement scheme where he would be less harmful, although, as is seen below, the resettlement scheme has been less than successful.

The above memo from the principal author to USAID (DeGeorges, 1987a) went on to stipulate to USAID that “the Michigan study and OMVG Working Document No. 20 (a classical environmental assessment using narrative matrices) (Samba & DeGeorges, 1987a; 1987b) must not be ignored. USAID must be willing to abide by Federal law and agency policy”.

¹³⁰ Malick John

¹³¹ French-Canadian Bob Demers.

¹³² David Hunsberger, who also did not support RONCO’s actions

It recommends that

USAID be accountable for and willing to, as are other branches of our government, enforce the laws of the land, in this case to the procedures which must be followed and parameters which must be addressed with regards to man and his natural resources in order to assure that development monies would have positive and beneficial effects on the very people whom we were trying to help. These laws included but were not limited to (DeGeorges, 1987a):¹³³

- **Foreign Assistance Act, Section 538b** concerning adequately addressing the environmental and social consequences of large dams in the tropics.
- **Foreign Assistance Act, Section 538g** requiring not only environmental evaluations, and recommendations for mitigation, but evaluations of alternatives.
- **Foreign Assistance Act, Section 538h** requiring the U.S. Secretary of Treasury to instruct U.S. executive directors of multilateral development banks to seek mitigation to adverse environmental impacts or adverse impacts (by dams) on indigenous people.
- **Foreign Assistance Act Section 117.63. Environmental and Natural Resources.**¹³⁴ If trends in degradation of natural resources in developing countries continues, they will severely undermine the best efforts to meet basic human needs, to achieve sustained economic growth and to prevent international tension and conflict...It is therefore in the economic and security interests of the United States to provide leadership both in thoroughly reassessing policies relating to natural resources and the environment, and in cooperating extensively with

¹³³ In the U.S. Foreign Assistance Act Of 1961 (PL 87-195) as amended in 2002 (USG, 2003), Section 538 (including 538 b, 538g, 538h) appear to have been removed jumping from Section 534 to Section 541.

¹³⁴ In the U.S. Foreign Assistance Act Of 1961 (PL 87-195) as amended in 2002 (USG, 2003), is Section 117 - Environment and Natural Resources.

developing countries in order to achieve environmentally sound development...President shall require all agencies and officials responsible for programs or projects under this chapter:

(A) To prepare and take fully into account an environmental impact statement for any program or project under this chapter significantly affecting the environment of the global common...

(B) To prepare and take fully into account an environmental assessment of any proposed program or project under this chapter significantly affecting the environment of any foreign country.'

- **Foreign Assistance Act, Section 118.64, Tropical Forests** assuring that development programs account for and look at alternatives to achieve sustainable use and account for impacts on biological diversity, denying assistance for any actions that may significantly degrade National parks or similar protected areas which contain tropical forests and deny assistance for construction of dams or other water control structures which flood relatively undegraded forest control lands.¹³⁵
- **Foreign Assistance Act, Section 119.66, Endangered Species.** Denies direct or indirect assistance for actions, which significantly degrade national parks or similar protected areas or introduce exotic plants or animals in such areas.¹³⁶

NEPA is a National law to which all branches of the government are bound and sets a set of guidelines for environmental review of all projects, stateside or overseas for which United States Government monies may be invested”.

This memo was ignored by USAID/Senegal decision-makers¹³⁷ who appeared to be the parties behind the reversal of ethical river basin planning efforts in the Gambia River Basin.

In an internal memo (DeGeorges, 1987c) to the USAID project manager¹³⁸, concern was raised that RONCO was analyzing complex 4-7 dam scenarios (e.g. Balingho/Kekreti/Kouya and Saltinho – giving a dam to the Gambia, one dam to Senegal, one to Guinea-Conakry and one to Guinea-Bissau) as opposed to “low end” single dam scenarios such as 1) Kouya with a bridge, 2) Medina Kouta with a bridge, 3) Sambangalou with a bridge and 4) Kekreti with a bridge. It was believed that insufficient data existed for the Saltinho Dam, which was in another river basin, Rio Corubal that drained into the new member state of Guinea-Bissau. It was recommended that now was not the time to throw this in, as it would mean omitting the environmental/socio-economic step in the planning process.

RONCO also claimed that costing of the upstream dams would not be possible and as a result, they would place an emphasis on calibrating an economical model for the Kekreti/Balingho scenario (politically preferred) as a demonstration

¹³⁷ USAID/Senegal Directress Sarah Jane Littlefield and her assistant Vito Stagliano

¹³⁸ David Hunsberger

model. The principal author was aware that Howard Humphreys¹³⁹, a British consulting firm, had cost estimates for Sambangalou. It was believed that the Polytechna Engineering¹⁴⁰ report (1981) also had cost estimates for the Medina Kouta and Kouya Dams. If not, an engineer using existing data could have produced preliminary cost estimates.

RONCO was also relying on older data from AHT¹⁴¹, Rhein Rhur¹⁴² and LRDC¹⁴³ consulting firm studies, which were biased towards irrigation agriculture as the solution to the Gambia River Basin's food needs. The RONCO team failed to contact the head¹⁴⁴ of USAID's GUARD project, who had been on the University of Michigan team, and served as acting chief of party helping to finish the study after the untimely death of the former chief of party¹⁴⁵. Dr. Gilbert played a critical role in putting together the Water Resource Management Report (University of Michigan, 1985a). In discussions with Dr. Gilbert by OMVG planning staff, (Samba, Dibba and DeGeorges), cost/benefits looked better for long-term improved swamp culture than irrigation. In addition, USAID's Mixed Farming Project was looking at improved rainfed agriculture (Gilbert, *pers. comm.*). RONCO's consultant, a Mr. Hesser said he would look into this. Michigan's final analysis concluded in favor of improved swamp culture over irrigation for many years to come (University of Michigan, 1985a).

By December 4, 1987, when the principal author was about to depart (most people with any knowledge of the truth were being scattered to the wind) for a

¹⁴⁵ Dr. Karl Lagler, the world famous Fishery Biologist from the University of Michigan

post as regional environmental advisor to USAID in the Caribbean, the RONCO chief of party sent a memo to the USAID/OMVG project manager¹⁴⁶ over his meeting with the OMVG high commissioner¹⁴⁷, stating that the high commissioner had pointed out that “the only remaining issue for OMVG was sequencing,” that is what would be the effects if either Balingho was built first or if Kekreti was built first. He said that the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD) was going to fund a study on sequencing: which dam first? In other words, we were back to square one where the principal author had started in 1982 with a politically preferred alternative. After an expenditure of US\$ 16 million, teaming the best and brightest from West Africa with the best and brightest from America to determine that both ecologically, economically and sociologically the risks were too high to justify the construction of the politically preferred dams, they were going to do go ahead with the construction anyway at the expense of the rural poor, which this “development” program was to have helped.

David Hunsberger had contacts with Jacques Bugnicourt (passed away April 2002 in Paris) head of a local French run NGO, *ENDA Tier Monde*, who in turn was associated with the Natural Resources Defense Council (NRDC),¹⁴⁸ a legal environmental watchdog in Washington, D.C. The principal author and the USAID project manager¹⁴⁹ made a pact, regardless of the impact on their professional careers, to provide the NRDC with all technical documents in an attempt to prevent the funding of the politically preferred Kekreti/Balingho dam scenario and to require additional studies and planning to determine the location of a high dam in Guinea-Conakry, based on sound hydrological, economic, ecological and sociological comparisons. Provided with all the technical and

¹⁴⁶ David Hunsberger

¹⁴⁹ David Hunsberger

political information, NRDC lawyers negotiated with USAID that any attempt to fund these dams without further study would result in a major lawsuit against the U.S. government. The principal author received one discrete call from the NRDC to the USAID/RDO/C office in Barbados where he was working, saying that he should not worry and that no dams would be built until more extensive studies were undertaken in the Gambia River Basin.

Thus, the attempts to destroy another river basin, creating social disruption, extinction or degradation of species and more food and economic dependency towards the West, were put to a halt. Was this the policy of the U.S. Government through USAID or was it the consequence of the bureaucratic structure within USAID, which promoted people for moving money as opposed to achieving real economic development? Certainly, at times, Robert Thomas Hennemeyer, the U.S. ambassador in the Gambia and the USAID directress in Senegal (OMVG Project run out of Senegal Office as opposed to USAID/The Gambia) were diabolically opposed as to where the OMVG should be going and who should be its high commissioner. The ambassador wanted the then high commissioner Malick John, removed on corruption charges, while Ms. Littlefield, the USAID directress, opposed this.¹⁵⁰

In 2005, after about 17 years, the appropriate choice in dams appears to be made.

“The Gambia River Basin Development Organisation (OMVG) is to implement new hydroelectric projects in Senegal and Guinea-Conakry to help to reduce local power shortages. A hydroelectric study for the benefit of OMVG is to be launched, with the aid of a US\$ 5.35 million grant from the Tunis-based African Development Fund (ADF). The 'Multinational Electric Power Grids' project aims to develop the region's largely unexploited energy potential, and leave it less dependent on petrol. Two large dams are planned: the

¹⁵⁰ David Hunsberger had proof of US\$ 15,000 in goods taken by the High Commissioner, small change in terms of foreign aid.

first located in Sambangalou, a village in southern Senegal at the river Gambia, the second at Kaléta, on the Konkouré river, central Guinea. The Sambangalou alone will have a capacity of 400 GWh. Along with the hydro plants, the project will feature a regional integration of power grids in the OMVG's four member countries, the "Gambia, Guinea-Conakry, Guinea-Bissau and Senegal" (International Water Power and Dam Construction, 2005).

It is likely that modeling of the Sambangalou on downstream hydrological and salinity regimes would be wise, as well as a closer look at the inundation zone. It is likely that a full blown environmental assessment should be undertaken for the Kaléta dam, if it has not already been undertaken. Funded by the African Development Bank/*Banque Africaine de Developpement* (ADB/BAD), in 2003, the consortium of *Groupement Coyne et Bellier - Tecslt - Coba* (COTECO) confirmed the technical, economic and environmental feasibility. The report states that

"the environmental and socio-economic impacts of the Sambangalou hydropower project and possible mitigation measures...revealed that creating a 181 km² reservoir upstream of the River Gambia will reduce the water level downstream, and the resulting low flows will keep the saline wedge of the Gambian estuary some 100 km downstream of its usual mean location. It will thus make more than 7,000 ha of arable land (in the Gambia) free from salty water" (Gambia Daily News, 2005).

As is seen below, with appropriate flow regulation there were many more ha available for both improved swamp culture and irrigation (see Section 7.9.8.2, The Gambia River). Are we once again seeing agriculture and people sacrificed for revenue generating electricity that will likely provide little benefits to rural inhabitants who are not connected to the power grid?

7.7.6 Other River Basins

With regard to the Lake Chad Basin study, this was a classical “table top development study” funded by UNDP, a joint venture in 1980 between Dwars, Heederik en Verhey (DHV)¹⁵¹, a Dutch consulting firm, *Société Grenobloise d'Etudes et d'Applications Hydrauliques* (SOGREAH)¹⁵², a French consulting firm, and Gannett Fleming Corddry & Carpenter (GFCC), an American consulting firm for whom the principal author worked. Two members of the team made a trip to the Lake Chad Basin and collected reports. The principal author, as a team member responsible for assessing impacts on fisheries who had never visited the basin, spent two days in Paris meeting with French fishery biologists to obtain their ideas, concerns and recommendations. The entire team then met for about five days in Chamrousse, a French ski resort, and planned development activities for the basin. Some of the consequences are seen below.

Additionally, case studies are brought in which are taken from the literature concerning ecological and sociological impacts from dams on rivers in Sub-Saharan Africa. Some are discussed in greater detail than others. Impacts associated with dams in the Zambezi River Basin are highlighted in some detail.

7.8 ENVIRONMENTAL COSTS OF DAMS AND RELATED DEVELOPMENT IN AFRICA

7.8.1 Dam Impacts on Floodplains

As is seen below, the major adverse downstream impact from dams on African river system is the modification of flood regimes to the detriment of the ecology,

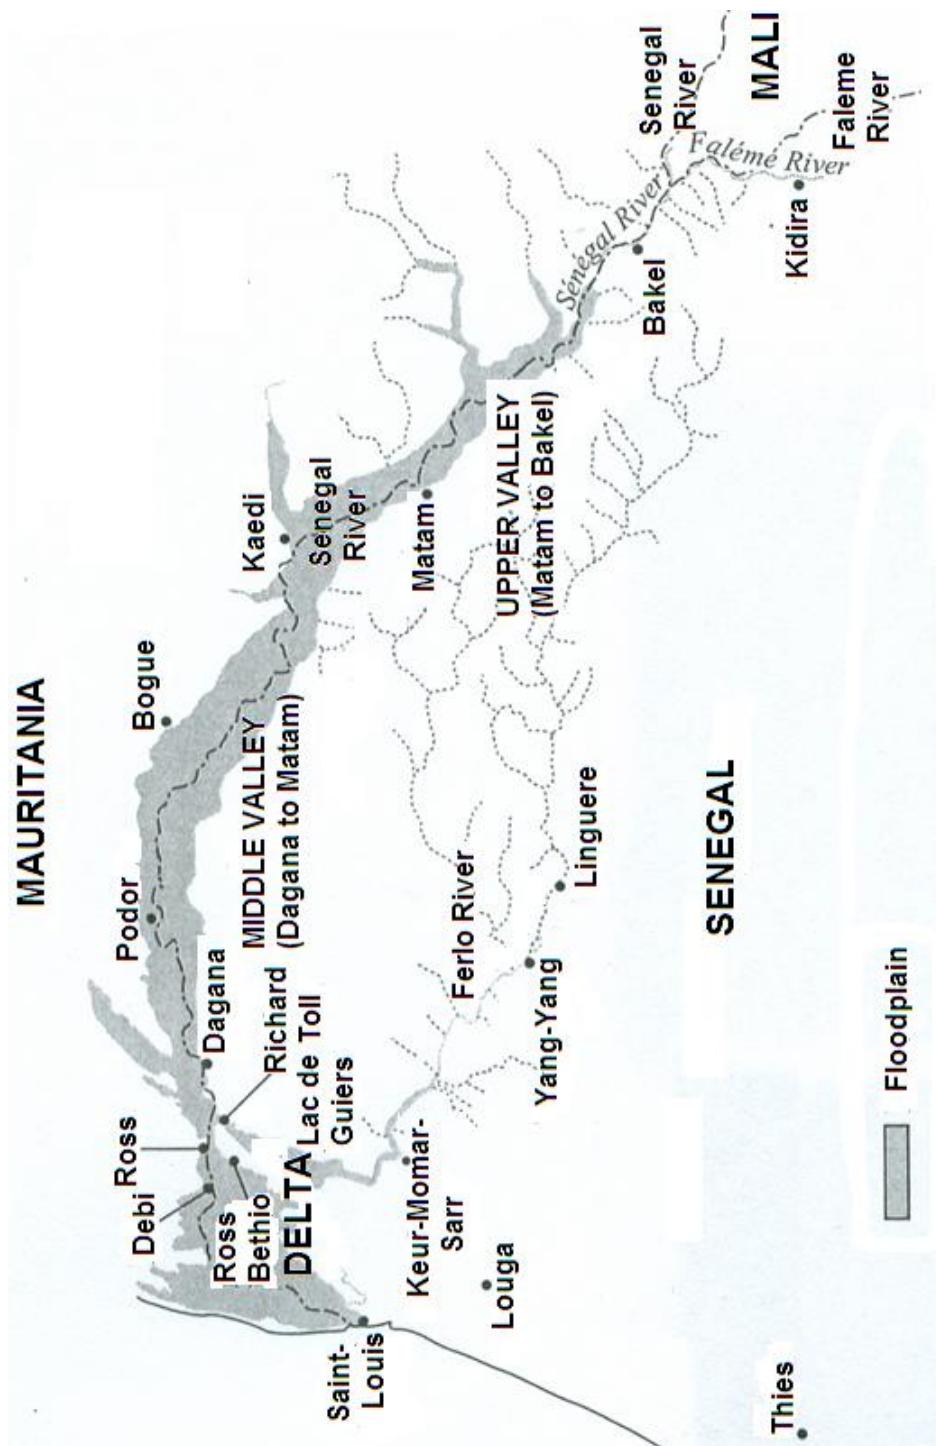

¹⁵¹ DHV Group, Laan 1914 no. 35, P.O. Box 219, 3800 AE Amersfoort, The Netherlands, 31-33-468-3700, info@dhv.nl

¹⁵² Sogreah International, 6 Rue de Lorraine, 38130 Echirolles, BP 172, 38042 Grenoble Cedex 9, France, sogreah@sogreah.fr, Tel: 04-76-33-40-00, FAX: 04-76-33-42-96

traditional production systems and ultimately humans and their survival. African floodplains, especially in the low rainfall Sahelian and Sudano-Sahelian zones, are among the most productive and diverse ecosystems on the continent, often an artery of life in an otherwise low production environment. They serve as spawning and nursery grounds for fish, provide critical waterbird habitat, are used for recession agriculture after the flood passes and are critical dry season grazing grounds for both livestock and wildlife. The loss of these floodplain systems from “development” has been devastating to communities all over Sub-Saharan Africa. These descriptions provide quantitative estimates on floodplain losses from dam construction.

7.8.1.1 Senegal River

For centuries, the annual floods of the Senegal River have been the lifeblood of flood recession agriculture, fishing, and cattle grazing for hundreds of thousands of people (Figure 7.4). The rainy season in the upper watershed traditionally occurred between June and October and resulted in downstream flooding between July and November (Gould, 1981). The floods provided nutrients to the floodplain and coastal fisheries and recharged the aquifers on which villagers depended for their domestic water supplies. Retreating floodwaters enriched the soil by depositing nutrient-rich silt on the land, providing both agricultural land and pasture.

Source: Boone (2003) with permission, Cambridge University Press.

Figure 7.4: Senegal River floodplain

Flooding occurred along a 600 km (360 mi) stretch of the river just below Bakel, with floodplains being as wide as 20 km (12 mi) in the Middle Valley, from Dagana to Matam (Boone, 2003). FAO (1997) estimates that prior to the construction of the dams “the floodplain of the Senegal stretched up to 30 km in width, and ran 600 km downstream of Bakel. It covered about 1 million ha and supported farmers, pastoralists and fishing communities. Up to half a million people depended on the flood-related cropping in the ‘waalo’ (and ‘falo’) land of the floodplain” (see Chapter 2, Figure 2.2: Cross-Section of Middle Valley, Senegal River showing makeup of *leydi* territorial units).

With the Manantali Dam in place, it was estimated that flooding would be reduced from 459,000-549,000 ha during an average flood in 1980 (pre-dam) to 190,000 ha by 2028 under full development of irrigation, hydropower, navigation, etc. (GFCC, 1980b; 1980d). An artificial flood was planned for 15 years to assure inundation of 100,000 ha of flood recession land, after which it would be stopped as irrigation took over (GFCC, 1980b). According to Koopman (2004), in one area artificial floods were so weak that flood recession agriculture was only possible in two of the last 15 years. As will be seen below, current artificial flooding allows an average of about 50,000 ha available for recession agriculture in the Senegal River Basin.

7.8.1.2 Gambia River floodplains

Where floodplains tended to dominate in the Senegal River Basin’s aquatic and terrestrial production, the extensive mangrove systems dominate aquatic production in the Gambia River Basin (GRB). There were 158,000 ha of floodplain; 109,000 ha of floodplain in the Gambia and 49,000 ha in Senegal; it is unclear what percentage was true floodplain versus rainfed swamp (DeGeorges, 1987d). The FAO (1985 *In:* Harding & DeGeorges, 1987) estimated 10,000 ha of river fed floodplain on the Gambia River. To date, no dams have been built.

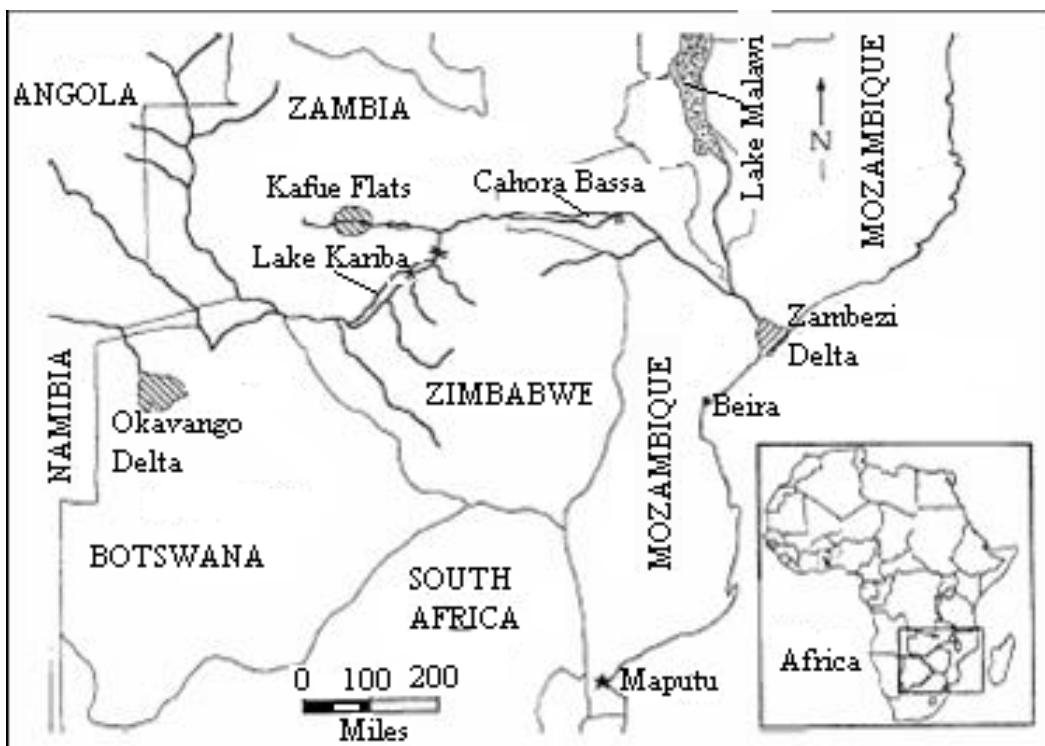

7.8.1.3 Impacts of Cahora Bassa on downstream flooding, Zambezi Delta, Mozambique

Operational since 1974, “the negative social effects of Cahora Bassa were linked to its hydrological and ecological impacts” (Isaacman & Sneddon, 2000) (Figure 7.5).

“The Zambezi basin below Cahora Bassa covers an area of approximately 340,000 km² from the upper Rift Valley highlands to the Zambezi Delta. The Lower Zambezi is a complex physical system with four river-floodplain zones comprising narrow gorges, mobile sand-braided reaches, anabranching reaches, and coastal distributaries.

Discharges below the gorge since construction of Cahora Bassa Dam are nearly constant throughout the year. The magnitude of monthly flows is sharply reduced during the entire flooding season, including a 64% reduction in the mean monthly flow during February-April and 45% reduction in January and May. Average monthly flows in November have nearly quadrupled, from 542 m³/s to 1,958 m³/s.

Flood peaks during the mid-1990s, when turbines were not operating, were derived from local runoff in the Lower Zambezi as Cahora Bassa released a constant discharge of about 1,700 m³/s. Flood peaks in the Delta below Cahora Bassa dam reached only 3.6 m in 1993. Overall, the average duration of flooding has decreased sharply” (Beifuss & dos Santos, 2001).

Source: Davies, Beilfuss & Thoms (2000) with permission, E.Schweizerbart'sche Verlagsbuchhandlung.

Figure 7.5: Zambezi River Basin

7.8.1.4 Kafue floodplains, Zambia

Under natural conditions, the annual variation in the area of inundation on the Kafue Flats was from a minimum of about 300 km² to in excess of 5000 km², varying with rainfall from year to year. The vegetation of the flats was zoned according to the flood regime and the soil as woodland savannah (predominantly acacia), termitaria grasslands, permanent swamps (reeds and papyrus) and floodplain grasses/sedges. About 700,000 people live on or in the vicinity of the Kafue Flats (DFID, 2002).

Constructed in the 1970s, when full, the Kafue Gorge Reservoir inundates the eastern half of the Kafue Flats permanently, covering 600-1600 km² (60,000 to 160,000 ha) of former seasonally inundated floodplain such that the downstream

half of the Kafue Flats is now considered part of the Kafue Gorge Reservoir (Figure 7.5). When full, the Kafue Gorge Reservoir inundates the eastern half of the Kafue Flats up to Lochinvar National Park (Kamwenesche, Beilfuss, & Simukonda, 2002). In order to keep up with power demand, the Itezhitezhi Dam was constructed at the western side of the Kafue Flats, eradicating the seasonal floods over the remaining part of the floodplain. The Itezhitezhi Dam releases water to the Kafue Gorge Dam during dry periods. The construction of the Itezhitezhi Dam commenced in 1973 and began impounding water in December 1976 (WWF/Netherlands, 2002). The Itezhitezhi Dam assures an adequate year-round flow of 120 m³/sec to the Kafue Gorge Dam turbines to produce 450 MW of electricity (DFID, 2002).

The construction and operation of the dams has had a major impact on flooding. Releases from Itezhi-tezhi have meant almost no change in the maximum area flooded each year. While maximum areas inundated remain about the same, the duration of flooding has been diminished since the Itezhitezhi Dam was built (DFID, 2000). While the temporal pattern of the natural flow regime is maintained, on average, wet season flows to the flats are reduced and dry season flows are enhanced, which along with the Kafue Gorge Dam results in the annual minimum flooded area increasing from about 300 km² to about 1500 km², a 20% loss in the original flood recession area (Acreman, Farquharson, McCartney, Sullivan, Campbell, Hodgson Morton, Smith, Birley, Knott, Lazenby, Wingfield & Barbier, 2000; DFID, 2002). Due to increased dry season flows, permanent lagoons have formed where ephemeral aquatic habitats existed before and “in part because of the inundation and backwater effects caused by the Kafue Gorge dam” (DFID, 2002). “At the downstream end of the Flats, the minimum water-level has been raised by about 3 m and the difference between maximum and minimum levels is now 1.2 m where under natural conditions it was in excess of 4 m. This has affected both the ecology and livelihoods of people utilizing the natural

resources of the Flats" (Acreman, *et al.*, 2000). "In broad terms the western half of the Flats is drier (i.e. frequency and duration of flooding is considerably reduced), whilst the eastern half of the Flats is wetter (i.e. frequency and duration of flooding has increased) than they were prior to dam construction" (DFID, 2002).

The greater dry season inundation is because of elevated water levels at the downstream end of the flats from backwater effects caused by water storage behind the Kafue Gorge Dam. Natural dry season recession could be simulated if the Kafue Gorge Reservoir was drawn down further earlier in the dry season (Acreman, *et al.*, 2000).

"Zambia Electricity Supply Corporation (ZESCO) is obliged to maintain a specified minimum flow ($40 \text{ m}^3/\text{s}$) in the river between Itezhitezhi and Kafue Gorge, to preserve the ecological habitat and to service other water users. Water is abstracted for a variety of purposes, including municipal supplies and irrigation – primarily sugar cane growers (the largest being the Zambia Sugar Company (ZSC) and winter wheat producers" (DFID, 2002).

This amounts to 15% of the live storage. In order to replicate the natural flooding regime, a daily minimum flow of $300 \text{ m}^3/\text{sec}$ is released over a four-week period each year. This is slightly less than the natural mean annual runoff of the whole catchment of about $350 \text{ m}^3/\text{sec}$ (DFID, 2002).

The local attitude toward floodplain resources (particularly wildlife and fisheries) is one of resignation, the resources belonging to outsiders (Kamwenesche, *et al.*, 2002). Up to 250,000 cattle graze the flats during the dry season along with some recession agriculture. The two national parks of Lochinvar and Blue Lagoon, along with the Nakambala Sugar Estate have blocked traditional cattle routes to water and grazing (DFID, 2002). Fishermen are predominantly immigrants and

safari or urban hunters do most of the hunting. The inhabitants have not been integrated into the management of these resources nor do they benefit from their exploitation (Kamwenesche, *et al.*, 2002). DFID (2002) distinguishes between locals fishing the flats and outsiders fishing the Itezhitezhi Reservoir. In addition, neither piped water nor electricity has benefited local inhabitants. Typical of dam development, 70-90% of the people still rely on firewood for energy and boreholes, wells and streams for water. This “open access” mentality is believed to be the net result of local communities losing control over management of natural resources in favor of centralized controls, which ultimately do not work very well in Africa.

7.8.1.5 Waza Logone floodplain, Cameroon

In the extreme Northern Province of Cameroon, just upstream from Waza National Park and its floodplains, the Maga Dam was constructed in 1979 on the Logone River, creating a 400 km² reservoir for the purpose of the *Secteur Expérimental de Modernisation de Riziculture de Yagoua* (SEMRY) rice irrigation scheme. In addition, on the left bank a 100 km long containment bank was constructed. Prior to the SEMRY scheme and Maga Dam, the value of the 3,382 km² Waza Logone Floodplain was estimated to be (Table 7.1):

Table 7.1: Economic benefits from annual flooding of the Waza-Logone floodplain

ECONOMIC SECTOR	TOTAL VALUE (Euros/US\$)	VALUE/UNIT AREA (Euros/km ² US\$/ km ²)
Pasture Benefits	6,075,100/7,168,618	1,800/2,124
Fisheries Benefits	3,425,600/4,042,208	1,005/1,186
Agricultural Benefits	705,900/832,962	215/254
Grass Benefits (Thatch, Baskets)	779,000/919,220	230/271
Surface Water	21,400/25,252	15/18
Supply Benefits		
NET BENEFITS	11,007,000/12,988,260	3,265/3,853

Source: Extracted from Loth (2004) with permission, IUCN.

The net result of these actions was estimated to be a reduction in flooding along the left bank of 964 km² (96,400 ha) for an average flood, an equivalent of about 30% in reduction of the normal area flooded of from about 3,382-3,571 km²/year to between 2,418-2,500 km²/year (Loth, 2004). The Waza-Logone Floodplain makes up a portion of the Logone Floodplain known as *Le Grand Yaéres* that floods an area of 6,000 km² on the Cameroonian side of the river or 11,000 km² (Loth, 2004), flooding both Cameroon and Chad (de Iongh, *pers. comm.*¹⁵³; Paul Loth, 2005/8/11). This caused severe social upheaval over an 800,000 ha (8,000 km²) area (Loth, 2004) when considering the loss of flooding in both Cameroon and Chad (de Iongh, *pers. comm.*; Loth, 2005/8/11).

Additionally, the SEMRY and other irrigation schemes in the Chari-Logone River Basins have had major regional impacts. Until the early 1970s, Lake Chad was the sixth largest lake in the world (Loth, 2004), averaging less than 7 m deep at 250 m above sea level (Chandler, 2001). The Chari-Logone River system to the south that drains the runoff from the Mandara Mountains of the Adamoua (Adamawa) Plateau in Cameroon accounts for 95% of the flow into Lake Chad. Today this river system accounts for 50% of the decline in water entering Lake Chad because of withdrawal for irrigation (Loth, 2004). The drainage basin of Lake Chad covers 2,500,000 km² over seven countries (Lycklama à Nijeholt, de Bie & Geerling, 2001). Geologically, Lake Chad was originally an ancient sea stretching as far as the Nile Basin, covering some 300,000 km², before practically drying up in the 18th and 19th centuries and partially regenerating in the 20th century (Agence France-Presse, 1999). At its peak in the 1960s, Lake Chad was about 23,000 km² (Benech, 1975), others say up to 26,000 km², the second largest wetland in Africa (USGS, 2004). During the drought of the early 1970s, the lake

¹⁵³ Hans H.de Iongh, Roghorst 343, 6708 KX Wageningen, The Netherlands 0317-424599,
DeIongh@cs.com

split into distinctly separate northern and southern basins. At the time when the two basins were totaled, the lake was about 13,000 km² (Benech, 1975).

By 2002, Lake Chad had been reduced to about 5% of what it had been (Loth, 2004; NASA, 2001) or somewhere between 1,150 to 1,300 km² compared to the 1960s. USGS (2004) estimates that it was reduced to 10% (2,600 km²) of what it had been in the 1960s (26,000 km²) (Figure 7.6). Lycklama à Nijeholt, *et al.* (2001) estimate that the surface area of Lake Chad had been reduced from 25,000 km² in 1960 to 2,500 km² by 2001. The northern part of the lake has basically disappeared. Chandler (2001), places the fluctuation in Lake Chad's surface area at between 25,900 km² in 1963 to 1,350 km², a 20 fold decrease in surface area, while Bomford (2006) places the current size as 1,295 km². According to the U.S. Geological Survey's website (USGS, 2004)

"changes include more enhanced exposure of dune features, increased wetland vegetation in the water (red), decreased wetland vegetation on the outside edges, decreased water surface (blue), and an increase in irrigation activities along the Chari River to the southeast. The decreased peripheral vegetation may suggest that these areas that can be classified as wetland are getting smaller as desertification takes place".

Loth (2004) and Coe and Foley (2001 *In:* NASA, 2001) state that: 1) climatic changes (e.g., lower rainfall, increasing temperatures and thus evaporation) and 2) the widespread use of water by humans (e.g., irrigation) are the main causes for this regional phenomenon. Coe and Foley (2001 *In:* NASA 2001) and Chandler (2001) calculate that a 30% decrease took place in the lake between 1966 and 1975. Irrigation only accounted for 5% of that decrease, with drier conditions accounting for the remainder. They noticed that irrigation demands increased four-fold between 1983 and 1994, accounting for 50% of the additional decrease in the size of the lake as noted by Loth (2004).

7.8.2 Dam Impacts on Groundwater

Without careful planning, modification of the flood regime can result in decreased infiltration inflow of surface to ground water and, as one approaches river deltas, exasperate saltwater intrusion into the groundwaters, which may be important for both irrigated agriculture and potable waters.

7.8.2.1 Senegal River

In the Senegal River, it was projected that irrigation in perimeters placed in the delta, where groundwater is saline and close to the surface, could result in soil salinization due to the rising of salt to the surface from the groundwater as a result of capillary forces. The mitigative action for this problem is to place irrigated perimeters away from areas with saline water tables close to the surface and/or to install expensive artificial drainage (GFCC, 1979).

7.8.2.2 Gambia River

Where planned, groundwater in the Gambia was good to excellent for irrigation and no significant impact was projected for this resource (Table 7.2).

**Table 7.2: Groundwater quality data for irrigation potential,
Gambia River Basin**

AQUIFER	IRRIGATION POTENTIAL

7.8.3 Dam Impacts on Surface Water Quality

7.8.3.1 Senegal River

In the Senegal River, overall changes in water quality due to proposed development were considered light to moderate. The most significant change projected was from the Diama Dam preventing salinity intrusion during the dry season to areas upstream of the dam. This change significantly altered water chemistry and aquatic communities in the portion of the river between the Diama Dam and Doué *Marigot*, where water will now remain fresh year-round (GFCC, 1979).

The Manantali Reservoir in Mali was predicted to behave like a monomictic lake, experiencing an annual thermocline (temperature change greater than 1 °C/m of depth) and an “overturn” of water once a year during the winter months (December-January) as the warmer surface waters decrease in temperature and thermocline breaks down. Especially in initial years, oxygen depletion and build up of toxic hydrogen sulfide were predicted in the bottom waters (hypolimnion) from anaerobic respiration. Discharges below the Manantali Dam of hypolimnial waters could result in fish kills from hydrogen sulfide up to 7 km downstream of the dam. Increases in aquatic plants or algal biomass could occur even further downstream from elevated nutrients levels (GFCC, 1979).

7.8.3.2 The Gambia

The freshwater reservoir, which would be created by the Balingho Barrage, would extend upstream to Kauntaur. Tidal action would be eliminated upstream of the barrage. The reservoir was predicted to suffer from salinization, acidification and

low oxygen levels, taking years to develop a stable aquatic food chain and a viable fishery. The high dams in the headwaters of the Gambia River would experience some of the same phenomena as described for the Manantali Dam on the Senegal River, both rivers having their origins in the Fouta Djallon Mountains of Guinea-Conakry.

7.8.4 Invasive Plants behind Dam Reservoirs

Once reservoirs are created in the tropics, they are targets for many invasive species, especially floating aquatic plants, which can impact navigation and result in tremendous losses of water from evapotranspiration, blanketing areas acting as “cloud cover” so that phytoplankton cannot photosynthesize. This results in fish kills, as oxygen is used up because respiration exceeds net primary production. Blankets of floating aquatic plants also provide habitat for disease vectors such as those that carry malaria and schistosomiasis. These are common problems all over Africa in both natural bodies and human-made lakes.

7.8.4.1 Senegal River

Salvinia spp., *Typha spp.*, *Pistia spp.* have all been problems (GFCC, 1980g). Biocontrol and water management helped control *Pistia spp.* Water hyacinth (*Eichhornia crassipes*), the world’s worst waterweed, is being sold as an ornamental at plant nurseries in the cities of Saint Louis and Dakar. If water hyacinth plants were somehow transferred to the river upstream of the Diama Dam, which is only 27 km upstream of Saint Louis, a new ecological disaster would emerge (Kloff, 2002). Fishing in the Diama Reservoir is seriously hampered by the dense stands of *Typha spp.* and by the floating invasives *Pistia stratiotes* and (since 1999) *Salvinia molesta* that are blocking the channels (Hamerlynck, Duvail, & Old Baba, 2000). In addition, the 16,000 ha Djoudj

National Bird Sanctuary and Diawling National Park across the river in Mauritania have both been threatened by invasive plants as noted above. Biological control using a weevil *Cyrtobagus (Cyrtobagous) salviniae* is helping to control *Salvinia molesta*. *Salvinia* “forms a substrate for other invasive weeds, exhausts the river’s oxygen and increases the habitat for disease-bearing snails and mosquitoes” (UNEP-WCMC, 2002).

7.8.4.2 Gambia River

A “red flag” was raised as a word of precaution. The plans of putting dams on the Gambia River were predicted to be in jeopardy due to the introduction of water hyacinth, *Eichhornia crassipes*, into the Gambia. This ornamental salt tolerant plant was originally restricted to freshwater garden and hotel ponds in the Banjul area, but began to slowly work its way upriver. With the creation of freshwater reservoirs, the ideal habitat for this plant, concern was raised for its proliferation. An example was given of Louisiana, USA, in which ten plants proliferated 655,360 new plants in one eight month growing season. In the Gambia and Senegal, the growing season would be year-round. Invasion by water hyacinth could (Samba & DeGeorges, 1987a):

- 1) Result in tremendous losses of water destined for other priorities through evapotranspiration.
- 2) Result in habitat for snail and mosquito disease vectors.
- 3) Increase the rate of sedimentation into reservoirs.
- 4) Cause navigational hazards.
- 5) Result in the loss of fish sets if wind blown mats move over a net, preventing access in a timely manner by fishermen and resulting in the catch rotting in the nets.

Since 1982, the OMVG Environmental Advisors had recommended a concerted effort to remove this nuisance from the Gambia River Basin (GRB) before it became well established. At the time of this assessment in 1987, no action had yet been taken.

7.8.5 Impoundment Fisheries from Dams

Impoundments can create rich fisheries, but often at the expense of richer fisheries in the downstream floodplains and estuaries.

An empirical relationship between total dissolved solids (TDS) and/or conductivity exists as an indirect way of measuring nutrient abundance linked to average depth. This relationship was first developed by Ryder (1965) and Ryder, Kerr, Loftus and Regier (1974) using total dissolved solids as a means of estimating potential annual fish yields in kg/ha. Henderson and Welcomme (1974) used more readily available conductivity data linked to average depth. The two parameters are interrelated $TDS\text{ (mg/l)}/0.65 \approx \text{Conductivity in umohos/cm}$. The higher the conductivity or TDS, the higher the nutrients and thus potential for primary and then secondary production. Average depth is an indirect way of measuring the productive littoral zone: the shallower the lake the more productive it is.

7.8.5.1 Senegal River

For the Manantali Reservoir on the Bafing River of the Senegal River Basin, the annual yield/catch of fish using the morpho-edaphic index (MEI)¹⁵⁴ graph from

¹⁵⁴ Morpho-Edaphic Index relates Surface Area, Volume and average depth as indicative of the abundance of the shallow littoral zone and thus age of lake (e.g. young/oligotrophic and old/eutrophic) as well as indirectly habitat and productivity, along with conductivity or total dissolved solids as an indication of nutrient abundance and potential primary productivity to support fish populations.

Henderson, Ryder and Kudhongania, (1973 *In:* GFCC, 1980a) was predicted to be between 65-86 kg/ha/year of fish. Using more recent morpho-edaphic indices formulas from Henderson and Welcomme (1974) and Schlesinger and Regier (1982), estimates would range from 13-21 kg/ha/year. Fish catches in the Manantali Reservoir cannot be considered a compensation for the losses in the Senegal River Valley. It is believed that a change in species composition occurred in the Diama Reservoir, with the elimination of estuarine migratory species and an increase of the more sedentary, opportunistic species (Clariidae [Clariidae], Cichlidae). However, surveys have not been undertaken and/or no data have been made available from surveys carried out by Senegal (Hamerlynck, *et al.*, 2000). Since the Manantali Reservoir surface area would vary between 477 and 275 km² depending on operational level (GFCC, 1980b), maximum fish yields would likely vary between a low of 358 metric tons/year to a high of 4,102 tons/year, depending on average operational level and ultimately the long-term productivity of the reservoir. This demonstrates the weaknesses of estimating change in nature and ultimately the importance of establishing long-term monitoring programs in collaboration with local resource users, in this case fishermen, to assure that the offtake is sustainable.

7.8.5.2 Gambia River

If a more “up-to-date” empirical formula is used, the following projections might be obtained for the proposed dams (Table 7.3).

These projections lie between the Samba and DeGeorges (1987a; 1987b) estimation for Kekreti of 550 metric tons/year (16 kg/ha/year), employing 500-1,500 full/part time fishermen, and the University of Michigan (1985a) study projections for Kekreti (64/kg/ha/yr), the Kouya Reservoir (26 kg/ha/year) and the Balingho (88 kg/ha/year). For planning purposes, these estimates are adequate.

Once a dam is constructed, as projected for the Manantali on the Senegal River, there would be an initial jump in fish production and annual yield/catch in the first 5-10 years, as organic matter and nutrients of terrestrial origin become available to the aquatic food chain. This would then drop and level off and would require a monitoring program to track this phenomenon.

Table 7.3: Projected fish yields (Kg/Ha/Yr) from proposed reservoirs on the Gambia River

Reservoir	Surface Area (m ²) 10 ⁶	Volume (m ³) 10 ⁶	Average Depth (m)	Conductivity (umhos/cm)	TDS (mg/l)	MEI (TDS)/Depth	Yield Metric Tons & kg/ha/yr
Balingho	716	1,400	1.96	60	39	19.9	5,069/70.8
Kekreti	338	3,500	10.4	55	36	3.5	1,470/43.5
Sambangalou	420	15,000	35.7	55	36	1.44	664/15.8
Kouya	101	4,270	42	55	36	1.44	160/15.8
Medina Kouta	210 ⁶	5,000	23.8	55	36	1.5	720/34.3

- 1) Average Depth = Reservoir Volume/Surface Area. b) Volume. c) Conductivity extracted from University Of Michigan (1985b) Water Quality Data. umhos/cm = usiemens/cm d) Total Dissolved Solids (TDS) = Conductivity (0.65 conversion factor), e) MEI = (TDS in mg/l)/Mean Depth (m). f) Assume Average Annual Air Temperature is 25 °C g) Metric Tons/yr = Yield (kg/ha/year) x (Surface Area 10⁶ m² x ha/10⁴ m²) x (tons/1000 kg), h) all average depths over 25 m calculate as 25m since greater depths fish production insignificant.
- 2) Using Schlesinger and Regier (1982) if >25 m average depth: \log_{10} Maximum Sustained Yield (MSY) in kg/ha/yr = 0.044 (Temperature °C) + 0.482 \log_{10} (MEI₂₅) + 0.021 & if <25 m average depth \log_{10} MSY = 0.050 (Temperature °C) + 0.280 \log_{10} (MEI) + 0.236
- 3) Prepared by principal author

Most importantly, as in the Senegal River, though there are projected increases in fish production within the impoundments, they would in no way replace the loss of the estuarine/marine fish complex projected to be lost.

7.8.5.3 Kariba Dam, Zimbabwe, Zambezi River

In Lake Kariba, excluding introduced species, more species could be found after than before impoundment in the same stretch of river. Thirty-one species were recorded in the middle Zambezi before the Kariba Dam was built. Forty species were recorded after impoundment (WCD, 1999). Marshall (1984 *In: Kapetsky & Petr, 1984*) found 40 species in the reservoir compared to 28 before. Jackson and Marmulla (2000) argue that pre-impoundment surveys showed that there was a limited variety, some 14 species of fish in the river, while today in the lake that number has risen to 47 species.

Lake Kariba is considered an oligotrophic system with low fish production potential (low nutrients, deep, shallow littoral area) (Marshall, 1984 *In: Kapetsky & Petr, 1984*; Jackson & Marmulla, 2000). Applying the Morpho-edaphic Index (MEI), it has the lowest potential yield of any of the large African reservoirs (Table 7.4).

Table 7.4: Projected fish yields from key reservoirs using the Morpho-edaphic Index (MEI)

LAKE	MEI	YIELD (kg/ha/yr)
Volta, Ghana	6.1	32.77
Nasser-Nubia, Egypt/Sudan	9.2	40.4
Kainji, Nigeria	6.6	34.6
Kariba, Zimbabwe	2.8	23.2

Formula: $Y = 14.3136 (\text{MEI}^{0.4581})$, where MEI = umhos/cm (conductivity)/Mean Depth, where Mean Depth = Volume/Surface Area, Y = Yield in kg/ha/yr

Note formula from Henderson and Welcomme (1974): $14.3136 (\text{MEI}^{0.4681})$ (Typo: 0.4581 in Kapetsky & Petr, 1984)

Source: Marshall (1982 *In: Marshall, 1984 In: Kapetsky & Petr, 1984*) with permission, UN & FAO.

The Kariba Reservoir, “extending 280 km from Devils Gorge to Kariba Gorge and 30 km at its widest point, is the third largest in Africa and inundates 5,250 km² of the Gwembe Valley floor” (Beilfuss & dos Santos, 2001). Using the MEI derived yield of 23.2 kg/ha/year and surface area, one would predict a potential annual fish catch of 12,180 metric tons, nearly one half of actual fish yields as indicated below. The low potential for fish yields is due to low primary production limited by phosphorus and nitrogen deposited upstream on the Barotse Floodplain in Zambia. Smaller inflowing rivers are richer in nutrients but contribute only 14% of the lake’s water. Nutrient losses in the outflow may be higher than imports (Kapetsky & Petr, 1984).

Marshall (1984 *In:* Kapetsky & Petr, 1984) estimates an inshore fishery of 2,000 tons/year, assuming 30% of the lake was fishable, and 8,000+ tons/year for the kapenta – not having Zambian statistics. According to Kureya (1998), “The fishery for kapenta of Kariba currently lands about 21,000 tons a year compared with an estimated potential of some 30,000 tons. The pelagic stocks are now exploited at close to their maximum”.

Most fish production is in shallow littoral areas. Within the inshore areas, crocodiles consume the equivalent of 10% of the catch. Catch composition is shifting toward benthic fishes, especially catfishes (e.g., *Synodontis zambezensis*). In 1989, there were nearly 2,000 artisanal fishers in Zimbabwe and nearly 1,000 in Zambia on the reservoir. Most fishers (91%) in Zimbabwe were full time and fished with 2-3 gillnets. The fishery was plagued by high catch spoilage and low productivity (Jackson & Marmulla, 2000).

In those areas where the Ba-Tonga were able to settle on the new reservoir shoreline, a huge area of mopani woodland, up to 4-10 km wide and extending 4-10 km into the lake (shallow water areas of 2-5 m deep), was cleared prior to the

lake filling. These clearings were separated by approximately 2.59 km (1-mile) wide strips of land where the trees remained and were used for a time for fish as breeding areas and breakwaters until the trees rotted and fell down. These areas, prepared by the then Rhodesian government for gillnetting by the Ba-Tonga fishermen and for deeper water commercial fishing, resulted in a thriving Ba-Tonga fishing industry (Thomson, *pers. comm.*). Kapetsky and Petr (1984) estimate that 954 km² ($\approx 18\%$) of the lake floor down to 20 meters deep was cleared. “Fish mongers”, as they were called by the Ba-Tonga, came from Bulawayo to trade for dried, smoked and salted fish, resulting in the development of a major fishing industry in the Binga District. Likewise, the commercial fishing company of Irvin & Johnson sub-contracted to the Ba-Tonga fishermen, collecting fresh fish with freezer boats. Since 1965 and continuing into the present, hundreds of tons of fish have been removed yearly by the Ba-Tonga in the Binga District (Thomson, *pers comm.*). Jackson and Marmulla (2000) argue that fishing camps for local residents have been established on the south shore, as at Sampakaruma. The poor physical and social conditions there over the years suggest that there is little sense of ownership of the site. It remains a mini-version, but more self-managed, of the migrant labor system, since most Ba-Tonga were settled inland. Colson (1971 *In:* Kapetsky & Petr, 1984) argues that the Ba-Tonga were not primarily fishermen and that a variety of sociological reasons inhibited them. Enthusiasm, which existed early on in the initial years with a jump in fisheries production, declined as the ecology of the lake settled down and fish yields stabilized at a lower level.

The introduction of exotic species such as kapenta (*Limnothrissa miodon*) from Lake Tanganyika into the Kariba Reservoir and eventually through the Kariba turbines into the Cahora Bassa Reservoir, both on the Zambezi River of Southern Africa, appeared to be positive, taking up the void in a biological niche, an open lake phytoplankton feeder, resulting from the damming of this river (see Chapter

4, Section 4.1, INTRODUCTION). This has resulted in the development of major fisheries and a major protein source for the poor of Southern Africa. Tigerfish (*Hydrocynus vittatus*) now live in the open water where they live on the kapenta. *Tilapia macrochir* have also been introduced and have become a major fishery resource (Marshall, 1984 *In: Kapetsky & Petr, 1984; Thomson, pers. comm.*).

To fish kapenta requires a special rig (Figure 7.7), shore facilities and the means to market. In Zimbabwe, the industry from the start has been dominated by commercial (white) operations, some offshoots of the largest fishing companies in Southern Africa.

In the mid-1980s, donors supported an indigenous cooperatively owned and managed rig on the Zimbabwe side as a means to enable resettled people to gain access to the industry. A permit was obtained from the authorities and there was some assistance given by a large company. In Zambia, an NGO, Harvest Help, opened up ownership of rigs to locals, expecting one rig to be attached to each multi-purpose cooperative. That venture has failed. The rigs are now leased to a large commercial operator out of Siavonga (WCD, 1999).

There was talk in 2003 of the unregulated artisanal fishing with gill nets having significantly reduced the Tigerfish and *Tilapia* populations as a sport fishery. This is confirmed by WCD (1999) stating that fisheries management on Lake Kariba had taken a turn for the worse over the last 5-8 years, as there was minimal management control. Recent sharp declines in Kapenta catches raise serious issues of management (WCD, 1999). This can only have worsened with the destabilization of Zimbabwe beginning in 2000 and continuing through 2008.

7.8.5.4 Cahora Bassa Reservoir, Mozambique

Fishermen were forced to change from riverine and floodplain harvesting techniques to deepwater lake fishing techniques. *Barilius zambezensis* and small *Barbus* species, which are characteristic of fast-flowing rivers, disappeared from Cahora Bassa following impoundment (WCD, 1999). Many riverine species likely disappeared, but there was a substantial increase in the harvest of kapenta and Tigerfish from the new reservoir.

Bernacsek and Lopez (1984 *In:* Kapetsky & Petr, 1984) estimate an annual sustainable yield of 6,700 tons of table fish (mainly *Hydrocynus sp.*, *Distichodus sp.* and *Labeo sp.*) and 8,000 tons of kapenta from the Cahora Bassa Reservoir. Kureya (1998) “estimated than no more than 5,000 tons of fish are currently taken throughout the country (Mozambique). Potential catches of 20,000 to 25,000 tons from Lake Niassa (Lake Malawi) and 15,000 tons for Cahora Bassa have been estimated”.

During the last decade, South African and Zimbabwean commercial fishermen using large boats and nets (Figure 7.7) depleted much of the kapenta population. These commercial fishermen have also undercut the effectiveness of local fisherman with canoes, many of whom rely on the catch to supplement household diets and income. Many peasants indicated that they had abandoned fishing altogether (Beifuss, Chilundo, Issacmen & Mulwafu, 2002). In recent times, it appears that the Mozambican government has begun a program to monitor the offtake of kapenta. The Mozambican government now has a statistician working with the kapenta fishermen to monitor their catches so as to assure sustainable management of this important resource. In addition, a major difference between the Kariba and Cahora Bassa kapenta fisheries is that most trees were removed within the Kariba inundation zone, while in the Cahora Bassa inundation zone the

trees were left standing. While fishing can take place virtually anywhere in the Kariba, the large areas of underwater forests in Cahora Bassa act as a safe haven for the kapenta from both the fishermen and the predatory Tigerfish, making it much more difficult to over-fish this fishery as compared to that in the Kariba (Hougaard, *pers. comm.*).

During the principal author's August 2003 visit to see students on the Cahora Bassa Safaris crocodile farm, local kapenta fishermen and the croc farm manager (Hougaard, Tarr & Caiwood, *pers. comm.*) explained that with the end of the civil war many people are moving onto the reservoir and are fishing with gill nets as a main occupation. The kapenta fishermen are all sport fishermen and are concerned that within five years, if the current uncontrolled pressure continues, the *Tilapia* and Tigerfish populations will be over-fished, ruining an excellent sport fishery, as well as a way for local people to feed themselves and earn a livelihood. Jasper Thornycroft (*pers. comm.*) claims that over-fishing of sport fish is already happening in Lake Kariba. The Zimbabwe Conservation Task Force is also concerned that fish are netted in the rivers flowing out of the Kariba Basin (restricted breeding areas) into the reservoir and that Zimbabwe is facing the total decimation of the Tigerfish population in Kariba (African Conservation Foundation, 2003). What currently exists is an "Open Access Resource" that needs to be turned into a "Common Property Resource".

The kapenta fishermen want to divide the reservoir into management units controlled by various fishing communities, setting aside nursery areas (e.g., tributaries into reservoir up which Tigerfish spawn, shallows where *Tilapia* spp. spawn), controlling access as a means of controlling fishing pressure, monitoring catch per unit of effort, mesh size versus fish size (try to find mesh size that leaves young fish uncaught), etc.

Shawn Caiwood (*pers. comm.*) believes that a human-fish-crocodile-human cycle is being set up in which people are over-fishing, resulting in less food for the crocodiles. This is causing an increased number of crocodile attacks on people. Shawn Caiwood explained that since the beginning of 2003, over a six-month period, 38 people had been killed by crocodiles, 15 within the previous two weeks (by mid-August). He explained that the government gave Piet Hougaard of Moçambique Safaris a contract to shoot 500 adult crocodiles, which the crocodile farm managed to stop since they were concerned about the potential for illegal exports and thus how the Convention on International Trade in Endangered Species (CITES) might react, with potential adverse impacts on their export business. Mozambique currently allows export (CITES quota) of 60 wild crocodile skins/year of which Tete Province has 20 CITES tags. Ironically, CITES requires that the crocodile farm release back into the wild 5% of the crocodile hatchlings at the age of one and one and a half years. The government does not agree with this but it assures the fulfillment of CITES requirements for farm raised crocodiles necessary to maintain a CITES quota that permits the international export of hides.

7.8.5.5 Volta River, Akosombo Dam/Volta Reservoir, Ghana

At the end of the 1960s, when the reservoir was first filled, annual fish yields were around 60,000 tons, in some years generating more income than sales of electricity (McCully, 2001).

In 1979, 20,000 fishermen on the lake caught over 40,000 tons of fish (McCully, 2001). The catch was projected to stabilize at around this annual yield/catch (Kapetsky & Petr, 1984). If one uses the estimated annual yield/catch of 32.77 kg/ha/year based on MEI from Table 7.4 and an average surface area of 8,500 km² (McCully, 2001), a yield of 27,855 metric tons/year of fish would be estimated. Although out of the same report as Table 7.4, but in a chapter by a

different author and somewhat contradictory, Vanderpuye (1984 *In: Kapetsky & Petr, 1984*) using MEI estimated a yield of 12 kg/ha/year versus an actual yield of 42.5-47.6 kg/ha/year from 1970 to 1976.

The MEI (Morpho-edaphic Index) of potential fish yield underestimates the potential since “essential nutrients” released by the breakdown and mineralization of the organic load are immediately picked up by algae and *Ceratophyllum* sp. (a submerged aquatic plant) from high water temperatures, resulting in quick turnover and high net productivity. Thus, TDS/conductivity provides an inaccurate status of the Volta Lake’s potential fish yield (Vanderpuye 1984 *In: Kapetsky & Petr, 1984*).

Little is known of the pre-impoundment fisheries, though early on in the reservoir’s life, catches were dominated by *Alestes nurse*, *A. dentex/baremose* and *Hydrocynus spp.* Experimental fishing between 1969 and 1973 indicated that Clupeidae (*Pellonula afzeliusi* and *Cynothrissa mento*) and Schilbeidae (*Eutropius niloticus* and *Schilbe mystus*) accounted for 57% of the catch by weight. Eight species/families made up 90% of the catch by weight: *Alestes baremose/dentex*, *A. macrolepidotus*, *Labeo* sp., *Lates* sp., *Chrysichthys* spp. and *Alestes nurse/leuciscus*.

The 80,000 displaced farmers gained little from this fishery. Formerly migrant fishermen who have become permanent settlers on the reservoir shore undertook almost all fishing (McCully, 2001).

7.8.5.6 Kainji Dam, Nigeria

Finished in 1968, the 1,300 km² reservoir/hydroelectric dam, located on the mainstream of the Niger 1,200 km from the river mouth, had a dramatic impact on fisheries both up and downstream (Läe, Williams, Malam, Morand & Mikolasek,

2003). After impoundment, there was a reduction in species diversity from 160 species to approximately 97 fish species in the inundation zone (Läe, *et al.*, 2003). The reservoir area was predicted to sustain annual fish yields of 10,000 tons. In 1970, two years after flooding, the reservoir experienced an initial burst of 28,600 tons (McCully, 2001), but by the mid-1970s had stabilized to around 4,500 – 6,000 tons/year (Kapetsky & Petr, 1984; McCully, 2001). This annual fish catch is only slightly higher than that taken from the stretch of river prior to being inundated by the dam (McCully, 2001).

7.8.5.7 Lake Nasser, Aswan High Dam, Egypt

Although the dam face of Lake Nasser (Aswan High Dam or Sadd el-Ali) is in Egypt, 150 km of its 500 km length lie in the Sudan and it is fed by nine Sub-Saharan countries that form its watershed: Burundi, the DRC, Egypt, Kenya, Rwanda, Sudan, Ethiopia (Eritrea), Tanzania and Uganda. The Aswan High Dam provides a classical case study not only on its socio-economic and ecological impacts, but also on the geo-politics of water and dams (see Chapter 13, Section 13.11.1, Nile Basin Water Conflicts). Reservoir fisheries yielded US\$ 7.2 million/year in the mid-1980s, with 95% of the yield being *Tilapia galilaea* and *T. nilotica*. It was believed that the 1977 landings of 22,500 tons/year were near the maximum potential of the reservoir and that anything above this resulted from increased fishing pressure into younger age-class fish (Abdel-Latif, 1984 *In:* Kapetsky & Petr, 1984).

7.8.6 Dam Impacts from Flow Regulation on Freshwater Floodplain Fisheries

“Everybody knows that there is no more fish in the river...Everybody knows that the river is ruined”. - Golmy Adama Diarra, a local Senegalese farmer in the Senegal River Valley, referring to the effects of the Manantali Dam (Probe International Website, 2004).

The fish species living in the main rivers of the Sahel have a life cycle that is adapted to the characteristic seasonal flooding, migrating onto the floodplain to spawn, and returning to the river bed with the new generation at the water's retreat. Terrestrial cattle droppings, decaying agricultural debris and grasses are recycled through the aquatic food chain, making a major contribution to fisheries production (Welcomme, 1975; WCD, 2000). The construction of dams in upstream areas and the management of the hydrological regime has in general been extremely destructive to these fisheries.

7.8.6.1 Impacts on floodplain fishery, Senegal River

During the wet season, from August through December, the Middle Valley exhibits characteristics of a freshwater fishery, relying on inundation of the floodplains to replenish the fish stock by providing habitat for breeding and a nursery for various species. During the dry season, the river waters gradually subside, forcing the fish populations to leave the floodplain and concentrate in the main channel. All freshwater fishes caught are consumed, including zero-age class fish (under one year of age). The more important families of freshwater fish consumed include Osteoglossidae, Mormyridae, Characidae, Citharinidae, Claridae (Clariidae), Schilbeidae, Bagridae, Mochocidae, Cichlidae and Centropomidae (GFCC, 1980a). GFCC (1980b) projects changes in fish yields from proposed development as follows based on estimates of traditionally flooded the annual yield/catch averaging 60 kg/ha flooded per year (GFCC, 1980b) (Table 7.5):

Table 7.5: Annual fish harvests in the Senegal River Basin before and projected harvests after various levels of proposed development, assuming annual average flood

Year	Metric Tons Fresh Fish/Year							
	Lac de Guiers	Lac R'Kiz	Aftout – es-Sahel	Diamal Dam	Senegal River Estuary	Manantali Reservoir	Flood plain	Total
1978 (a)	2,250	-----	5	7,500	4,000	-----	33,000	46,755
1986 (b)	2,750	1,200	5,000	4,500	----- (c)	4,000	31,800	45,250
1987 (d)	2,750	1,200	5,000	4,500	Same -	3,000	20,400	37,850
2002 (e)	2,750	1,200	5,000	4,500	Same	3,000	19,200	35,650
2003 (f)	2,750	1,200	5,000	4,500	Same	3,000	13,800	30,250
2028 (g)	2,750	1,200	5,000	4,500	Same	3,000	11,400	27,850

- a. Present Conditions, Floodplain of 549,000 ha
- b. Diamal Dam completed, estuary fishery is lost; increase in harvests occurs due to recharge of natural impoundments (Lac R'Kiz and Aftout-es-Sahel), some floodplain lost to agricultural development
- c. Estuarine Fishery as it presently exists is destroyed. 1987-2028, the same.
- d. Manantali complete. Significant loss of floodplain fishery due to decrease in magnitude and duration of natural flooding, and continued agricultural development; some flooding maintained artificially to assure recession agriculture. In the Manantali Reservoir, an initial flush of nutrients results in peak fish production followed by a drop and then stabilization of fish production as primary productivity levels off, typical of impoundment fisheries. Total area flooded \approx 340,000 ha.
- e. Same as in 1987 with continual loss of floodplain due to agricultural development. Total area flooded \approx 320,000 ha.
- f. Discontinuing artificial flooding results in significant loss of floodplain. Total area flooded \approx 230,000 ha.
- g. Same as 2003, with continued loss of floodplain area due to agricultural development and water used for hydropower and navigation, amounting to 190,000 ha total in floodplains.

Source: Extracted from GFCC (1980b), USAID public domain & principal author responsible in preparing table for GFCC

Both estuarine and floodplain fisheries have been significantly reduced. Only 16,000 ha of the artificial estuary have been put under management (Kloff, 2000; Hamerlynck, Duvail & Old Baba, 2001), compared to a planned 10,000-35,000 ha artificial estuary (DeGeorges, 1984), whereas to fully inundate the Aftout-es-Sahel would require the inundation of up to 100,000 ha (DeGeorges, 1984; Hamerlynck, Duvail & Old Baba, 2001). No reference can be found to artificially flooding *Lac R'Kiz*, so it is assumed that this has not happened. Invasion by

aquatic plants seems to be affecting fish yields on *Lac de Guiers* and the Diamma Reservoir.

Fish production in the river and estuary has dropped by 90% (GEF, 2002). This implies that estuarine yields of fish after the dams would have dropped to about 1,150 tons/year¹⁵⁵ and freshwater floodplain fishery yields would be down to 3,300 tons/year¹⁵⁶. GFCC (1980b) estimates that the estuarine area produced 11,400 tons of fish/year before the dams (Diamma and Estuary in 1978). Prior to the Manantali, an estimated 33,000 metric tons/year was harvested from the freshwater floodplain (GFCC, 1980b). Jackson and Marmulla (2000) and WCD (2000) estimate that 11,250 tons of fish per year from the Senegal River floodplain system were lost following dam construction (Jackson & Marmulla, 2000; WCD, 2000), resulting in a net yield of 21,750 tons/year. GFCC (1980b) estimates a loss of 12,600 metric tons/year from the floodplain once the Manantali was in place; resulting in a net yield of 20,400 tons/year. The net result is fishery yields without significant floods and estuarine management appears to have resulted in much lower yields than projected. Thus, if one tries to reconstruct an estimate of fish yields today one would get (Table 7.6):

¹⁵⁵ This would be a 90% reduction in the pre-dam estuary, which would include the 7,500 metric tons from the “Diamma Dam” area that was part of the estuary plus the 4,000 metric tons shown as the Senegal River Estuary, which is the portion of the estuary below the Diamma Dam face.

¹⁵⁶ This would be a 90 % reduction of the pre-dam floodplain catch of 33,000 tons/year. If the average flood, the case in 2007 was 50,000 ha/year at 60 kg/ha/yr, this would be a fairly accurate estimate of annual yields.

Table 7.6: Projected fish harvests based on review of literature after construction of the Manantali and Diamma Dams, Senegal River

Year	Metric Tons Fresh Fish/Year							
	Lac de Guiers	Lac R' Kiz	Aftout-es-Sahel	Diamma Dam	Senegal River Estuary	Manantali Reservoir	Flood plain	Total
Today	2,250 ---	---	2,286	4,500	1,150	3,000	3,300-21,750	16,486-34,936

Note: It was predicted that 5,000 tons of fish would be caught in the Aftout-es-Sahel after inundating 35,000 ha, but only 16,000 ha were inundated, meaning a yield of 2,286 tons.

Source: Principal author

Given that artificial flooding has been minimal, averaging 82,600 ha/year for only 7-8 weeks, one would tend to lean to the low side estimate (see Section 7.10.7.1, Senegal River). In 1980, 10,000 full-time and 10,000 part time fishermen were employed along the Senegal River and would have been adversely impacted by these changes (GFCC 1980b; 1980d). While prior to dam completion there would have been a net surplus of fish within the Senegal River Basin in 1980, GFCC (1980b; 1980d) estimated with human population growth and the projected adverse impacts on the riverine/estuarine fisheries from dams that by 2000 out of a demand for 110,930 metric tons and based upon a predicted harvest of 35,650 metric tons, a deficit of -75,280 metric tons. By 2028, there would be a demand for 240,120 metric tons/year and based upon a predicted harvest of 27,850 metric tons, a deficit of -212,270 metric tons/year. These deficits could only be made up by trucking in marine fish, through improved storage and preservation techniques (estimated for African inland fisheries that 50-70% of the catch lost between harvesting and marketing from bacterial degradation and infestation by insect eggs and larvae), and to a lesser degree fish culture (GFCC, 1980b; 1980d).

In 1992, a rural peasant farmers' association issued a manifesto, which asked the administrative authorities, in cooperation with the farmers, to regulate the artificial flood in such a way as to favor flood-recession farming and the reproduction of "river fish". They also asked that a land and development policy be evolved that would give priority, first to the present and future needs of river inhabitants, then to the present and future needs of the inhabitants of the rest of Senegal and which would take into account all possibilities for developing the land, not just irrigation. They received no reply (Adams, 2000b).

7.8.6.2 Impacts on floodplain fishery, Gambia River

The University of Michigan study estimates that there are 109,940 ha of wetlands in the Gambia and 49,500 ha of wetlands in Senegal, some of which may be rainfed and cutoff from flooding by the river. Though important, compared to the previously presented history of the Senegal River, the relative area flooded is very small.

About 30 species of fish have been identified, whose life cycle and thus production are tied to the freshwater floodplains. This helps explain why yields from freshwater fisheries in the Gambian and Senegalese portions of the Gambia River Basin in recent years have decreased as rainfall and corresponding flooding have decreased (Dorr, Schneeberger, Tin & Flath, 1985 *In: DeGeorges, 1987d*). This same phenomenon has been observed in the more extensive floodplain fisheries of the Senegal River Basin.

Jackson and Marmulla (2000) estimate that floodplains can provide an annual yield/catch of 200 – 2,000 kg/ha/yr. The GFCC (1980a) study used 60 kg/ha/year annual yield/catch for the Senegal River Floodplain fish projections. If the FAO (1985 *In: Harding & DeGeorges, 1987*) estimate of 10,000 ha of river fed

floodplain is accurate, a potential annual yield/catch of 600 metric tons from the Gambia River Floodplain is obtained by using the estimated yield for floodplains fish of 60 kg/ha/year from the Senegal River. This equates closely with the actual 637.2 metric tons/year of floodplain-tied fish from 1982/83 catch records (DeGeorges, 1987d). However, local fishermen at the time felt that fish yields were down due to the drought and decreased flooding. Much of this fishery would likely be degraded as flood regulation and conversion of land to pumped irrigation reduces habitat for floodplain dependent species. Only a long-term monitoring program would allow a more precise estimate of the annual yield/catch per ha from these freshwater floodplains and what might be lost if these floodplains were taken out of production from decreased flooding and/or conversion to irrigated perimeters for rice production.

7.8.6.3 Impacts on Zambezi Delta floodplain fishery

Traditionally, in the Zambezi Delta, fish were the most important source of protein for the local population, especially during times of food shortages. Seasonal fishing camps were established on the Zambezi Floodplains between the main Zambezi Channel and Mungari River Distributary. The annual months of low flows enabled a high catch of fish per-unit-effort because fishers were able to wade into the river using simple gill nets and baskets (Beilfuss, *et al.*, 2002). A total floodplain harvest of about 10,000 tons/year was estimated under historical flooding conditions (Beilfuss & dos Santos, 2001). Downstream of the Cahora Bassa Dam in the Lower Zambezi Valley, 83 species of fish are known to have occurred, many more than between Kariba and upstream of the Cahora Bassa Dam face before impoundment. Downstream of the Cahora Bassa Dam, most of the species are still found today but the size and quantity of fish have dramatically decreased and several species have disappeared – especially in the Zambezi Delta region (Beilfuss, *et al.*, 2002). Much of this has to do with the loss of the

floodplains from flow regulation for hydroelectricity (Beilfuss, *et al.*, 2002) by the Kariba, Cahora Bassa and Kafue Dams. The rapid rise and fall of the Zambezi River, caused by the operation of the Cahora Bassa Dam, is also blamed (for lower fish catches). Gill nets cannot be used under these circumstances. After the extensive delta flooding of 2001, fishing camps were re-established on the floodplains for the first time since the 1978 flood and fish harvests were the highest (in total catch and biomass) since Cahora Bassa was constructed (Beilfuss, *et al.*, 2002). The contribution to the loss of delta floodplains and thus fish production from the Kariba Dam versus the Cahora Bassa and Kafue Dams must still be determined.

7.8.6.4 Kafue Flats, Zambia

The modified flood regime is believed to have impacted fish productivity. Fisheries production has also been impacted by irrigated sugar cane farming on the southeastern side of the Kafue Flats: Zambia Sugar Company (ZSC) with over 10,000 ha and Ceres Farm with around 5,000 ha. These farms irrigate with water from the Kafue River and sugar-cane processing effluents rich in nutrients (WWF/Netherlands, 2002) and biological oxygen demand (BOD–oxygen consuming organic matter) are discharged back into the river. The nutrient rich effluents contribute to aquatic plant growth such as water hyacinth, “Kafue weed” (*Eichhornia crassipes*), that affects navigation of dugout canoes. Water hyacinth can cover an area of surface water as a mat, preventing phytoplankton from photosynthesizing and thus providing the life giving oxygen for fish and other aquatic life. Excessive hyacinth growth has suffocated fish in the river, thereby affecting the fishing (WWF/Netherlands, 2002). Likewise, the oxygen consuming organics in the effluent discharge can result in similar impacts.

According to DFID (2002), the average annual yield/catch between 1966 and 1977 prior to construction of the Itezhitezhi Dam was 7,820 tons and between 1978 and 2000 after construction was 6,719 tons. However, the latter period contains the extremely dry years in the early 1990s when lower catches might be expected. A student-t test showed no significant difference between pre- and post-dam catches. Likewise, Acreman *et al.* (2000) agree that the dry years had an impact on fisheries, but more importantly believe that the changed flood regime resulted in changes in fish species, decreased the catch per-unit-effort, and resulted in the number of fishermen declining from 2,634 in 1977 to 1,157 in 1985.

The fish ban during the fish-breeding season is not well enforced (Kamwenesche, *et al.*, 2002).

7.8.6.5 Waza Logone Floodplain, Cameroon

Excellent overviews of the Lake Chad Basin fisheries and the ties between fish production, annual yield/catch and floodplain inundation can be found in Durand (1977) and Blache, Milton and Stauch (1962). Iltis (1975) discusses the Yaéres Floodplains and associated species, while Benech (1975) describes the impacts of the 1972/73 drought on fish production in the Lake Chad Basin.

The Waza Logone Floodplain, making up a portion of the Yaéres,¹⁵⁷ supports a large fishery, both in its main river channels and permanent lakes and in flood-fed and seasonal creeks, ponds, depressions and other wetlands. The Waza-Logone

¹⁵⁷ “The floodplains are referred to as the Yaéres. It depends probably on the context. The Waza Logone floodplain mostly refers only to that part of the Yaéres that is located East of the Waza Park down to the Maga dam” (Loth, 2004/8/16). In Figure 7.9 7.8 the Yaéres looks to be most of the floodplain on the west bank of the Logone River.

portion of the floodplain covers from 2,418-3,382 km² (Loth, 2004). Traditionally, the Kotoko ethnic group controlled fishing, but in the last decade of the 20th century, the Musgum, who arrived in the 19th century, challenged the supremacy of the Kotoko over-fishing rights. This resulted in conflicts and an eventual agreement by the Kotoko over exclusive fishing rights (Loth, 2004). It appears that some of the traditional controls over managing the fishery resources, as described in Chapter 2, have been modified, many being lost. Fishing grounds became opened to everyone as “Open Access Resources” (Loth, 2004). The major period of spawning on the Yaéres Floodplains is from August to September (Iltis, 1975).

As water begins to spread onto the floodplain in July, catfish (*Clarias spp.*) are speared and clubbed in the shallows as they leave the river and pools of the dry season. The *grand pêche* begins at the height of the flood in September/October and lasts until January/February. By September, as the flood peaks, fishing camps are set up on the floodplain and fishermen employ traps to catch fish, primarily *Clarias spp.*, *Petrocephalus bovei*, *Brycinus nurse*, *Oreochromis niloticus* (*Tilapia nilotica*) and *Synodontis nigrita* that spawn in the *marigots* (distributaries off main river channel), moving onto the floodplains to grow and returning to the river with the recession of the floods. As the floodwaters recede, migrant fishermen move in to fish the *marigots* (distributaries off main channel onto floodplain) as fish return to the main channels. Fishermen leave the floodplain for a short time to fish the main channel of the river for the sardine *Alestes spp.* (*Salanga*), the last to arrive on the floodplain and the first to leave, returning to the main channel of the Logone River as the flood recedes, normally beginning in November. They then return to the floodplains to catch fish trapped in depressions left by the receding floods. Artificial fishing canals/trenches dug during the dry season join depressions to the river, acting as *marigots*. In January and February, fishermen use gill nets in the artificial hand-dug trenches and place

nets across the entrance of the canals as they enter the river chiefly for *Clarias spp.* (54%), *Oreochromis niloticus* (32%), *Hemichromis fasciatus* (3.7%), *Synodontis spp.* (3.6%) and *Ctenopoma petherici* (2%). From February until the flood returns in July, subsistence fishing or *petit pêche* is undertaken with set nets, cast nets and hooks in natural and artificial depressions. These hand-dug trenches often interfere with and are a major source of conflict with immigrating pastoralists and their cattle herds (Loth, 2004). Fishing is practiced year-round in the main river channel with gill nets, long lines, cast nets, seines and weirs (Iltis, 1975). Typical of African floodplain ecosystems, annual yield/catch of fish is estimated at between 40 and 60 kg/year of floodplain on the Logone Floodplain (Loth, 2004).

Fish yields prior to this development scheme were estimated to range between 12,000 and 15,000 metric tons (42-46 kg/ha/year) on the Waza Logone Floodplain. As a result of the SEMRY rice scheme, which included the Maga Dam and the 100 km long containment bank, 964 km² of the Waza Logone Floodplain was lost to the ecosystem, a 30% reduction in flooding with the width of the floodplain on the left bank of the Logone decreasing from 50 to 30 km. This reduced annual flooding from 3,382 to 2,418 km²/year. Fish yields, as a result of this development scheme, were reduced by 90%¹⁵⁸ in the portion of the floodplain taken out of production at an estimated annual loss of Euros 498,500/year (US\$ 588,230/year). Combined with over-fishing as the result of the weakening of traditional controls over access, many Kotoko fishermen left in search of better fishing grounds, moving to Lake Chad, where the reduced level of the lake over the decades has resulted in increased fish biomass concentrated in the remaining area of the lake and/or human-made lakes such as Maga and Lagdo. The number of fishers fell from an estimated 10,000 to 7,000 on the Waza Logone Floodplain (Loth, 2004).

¹⁵⁸ While there was a 30% reduction in flooding, a 90% reduction in fish yields was likely linked to other factors such as the reduced duration of flooding.

Grand Yaéres

On a grander scale, biologists from the Overseas Office for Scientific and Technical Research/*Office de la Recherche Scientifique et Technique Outre-Mer* (ORSTOM),¹⁵⁹ Christiane Leveque and Jacques Quensiére (*pers. comm.*) believed that there would be a regional impact if the Yaéres Floodplain was completely lost, since many areas within the Lake Chad Basin were restocked from the nursery grounds of this floodplain (Table 7.7):

Table 7.7: ORSTOM biologists' projections of fish losses if inundation of Yaéres Floodplain ceased as result of SEMRY rice scheme

AREA AFFECTED	ANNUAL HARVEST (METRIC TONS)	ANNUAL HARVEST IF GRAND YAÉRES FLOODPLAINS LOST COMPLETELY (METRIC TONS)
El Beid (Drains Yaéres towards Lake Chad)	1,400	0
Yaéres	5,700	0
Logone Gana	100	25
Chari Delta (Entrance Into Lake Chad)	2,000	500
Lake Chad	103,400	103,400
TOTAL	112,600	103,925

Note: that the yield of fish from the Yaéres is more than half that projected by Loth (2004) for the Waza Logone portion of the Yaéres.

Source: Principal author, Draft report prepared October 1979 for UNDP sponsored environmental assessment, "Lake Chad Basin Study" (DHV, GFCC & SOGREAH, 1980) with permission, UN & UNDP.

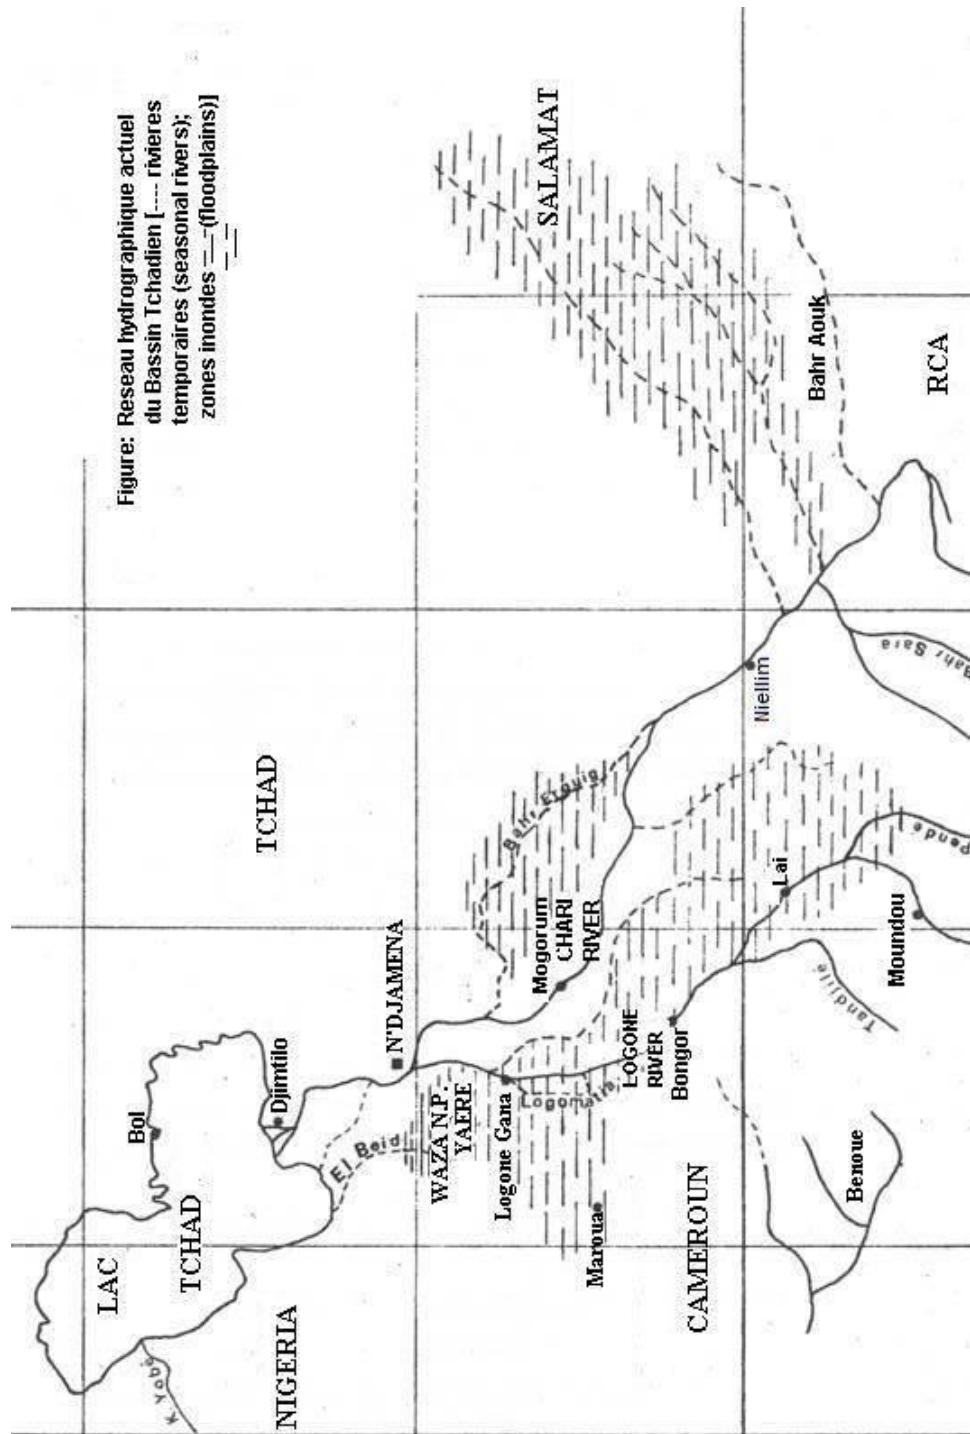

These yields are based on the surface of Lake Chad remaining at 9,000 to 10,000 km² of the early 1970s, while it is known that today the lake is between 5-10% of what it was at that time: a maximum of 1,300 to 2,600 km². The projected loss of fish was based on the ORSTOM biologists' beliefs that loss of the Yaéres

¹⁵⁹ORSTOM today is called: L'Institut de Recherche pour le Développement (IRD), <http://www.ird.fr/>.

Floodplain would cause a disappearance of the migratory *Salanga* fishery of the El Beid, the Chari Delta and main river (Leveque & Quensiere, *pers. comm.*), consisting of the following species whose lives are closely tied to spawning on the floodplains: primarily *Alestes baremose* and *A. dentex*, but also *Schilbe uranoscopus*, *Brachysynodontis batensoda* and *Hemisynodontis membranaceus*) (Benech, 1975) (Figure 7.8).

Lake Chad proper would not be severely impacted, assuming the lake remained at about 9,000 to 10,000 km², since most of its catch is made up of sedentary non-migratory fish species that would make up for loss of the migratory fishery to some degree by increased production primarily from *Tilapia nilotica*, *Clarias*, spp., *Gymnarchus niloticus*, *Heterotis nilotica* (Leveque & Quensiere, *pers. comm.*) and *Synodontis membranaceus* (Blache, *et al.*, 1962).

Benech (1975) demonstrates that initially as the lake dried up, fish catches went up, but as Lake Chad's size decreased, the *prises par unité d'effort*/catch per unit of effort (PUE/CUE) went down, requiring intensified efforts to catch the same quantity of fish. By 1973, the catch per unit of effort was almost zero due to the falling lake levels and the isolation of the lake from the riverine system, implying a drastic decline in catch yields. By May 1973, fishing in the Chari Delta had almost stopped. Fishing in the delta for *Salanga* (*Alestes* spp., etc. migratory floodplain fishery) was primarily done by part time fishermen agriculturists. Fish yields in the delta were estimated to have been 5.5% in 1973 compared to the season of August 1971-July 1972 preceding the drought.

Source: Durand (1977) with permission, UN, FAO & UNDP.

Figure 7.8: Links between Grand Yaéres and other floodplains as a spawning and nursery ground for fish emanating from Lake Chad/Chari Delta

Professional fishermen migrated to the isolated northern basin of Lake Chad, where the *Salanga* were trapped from making their migration up the Chari Logone and El Beid Rivers to spawn on the Yaéres Floodplain. This is the major reason why the *Salanga* fishery showed such high yields in the 1973/74 season. There was, however, a large dieoff of fish in the northern basin from oxygen depletion. The increase in *Banda*, pieces of smoked fish, came 98-99% from the northern isolated sub-basin of Lake Chad. Traditionally, *Banda* would have come from large fish such as *Lates niloticus*, *Bagrus spp.*, *Heterotis spp.* and *Hydrocyon brevis*. However, these species began dieing out from lack of oxygen in much of the lake. By 1975, key species that began taking over under low oxygen conditions were *Tilapia spp.*, *Clarias spp.*, *Polypterus senegalus*, *Brienomyrus niger* and *Alestes nurse*. Only the *Tilapia spp.* and *Clarias spp.* were of economic importance (Benech, 1975).

Concern was raised that loss of other floodplains within the Lake Chad Basin such as the Bahr Egig and Salamat could result in further reductions of fish harvests (Leveque & Quensiere, *pers. comm.*).

The environmental assessment prepared for the UNDP (DHV, GFCC & SOGREAH, 1980) was so concerned for maintaining the Yaéres Floodplain that it stated,

“the importance of the Yaéres to current and future food production in the basin is so great that immediate studies should be made for the purpose of preserving the productive capacity of the Yaéres as long as possible”.

It did not show as great a concern for the continued loss of habitat from the drying up of Lake Chad, a large part due to withdrawal of water in the Lake Chad Basin for irrigation. Once again, a combination of dams and irrigation in the Lake Chad Basin, has not only impacted local floodplain fishery production, but has greatly

diminished the productivity of Lake Chad and the Chari Delta entering the lake that during their peak production are said to have yielded as much as 140,000 metric tons of fish/year in the 1960s. Given the current state of Lake Chad and environs it would be surprising if the reported yield of 60,000 tons/year (Agence Presse France-Press, 1999) is accurate!

The ORSTOM biologists¹⁶⁰ also believed that some of the projected losses in fish production could be made up by better handling, storage and preservation of fish. Due to poor smoking, drying and storage techniques, an average loss of 25% of the processed fish occurs between the fishing village and markets, while another 25-50% of the fish are lost between the point of capture and arrival in the villages (Leveque & Quensiere, *pers. comm.*). Fish culture was discussed, but this could never mitigate the loss of a natural fishery.

7.8.6.6 Kainji Dam, Nigeria

Downstream fish catches on the Niger River fell by 60-70% (Awachie & Walson, 1978 *In: Läe, et al.*, 2003; McCully, 2001).

7.8.6.7 Aswan High Dam, Nile River, Egypt

Fish species north of the dam in the river declined from 71 to 31 species once the dam was in place (Kapetsky & Petr, 1984). Abdel-Latif (1984 *In: Kapetsky & Petr*, 1984) states that downstream of the dam in the freshwater portion of the river, regulation of flow and loss of silt created lentic (lake-like) conditions in which phytoplankton production increased, favoring a change in species, where *Tilapia*, especially *T. nilotica* went from 25% of the catch by species before the construction of the high dam to 75% of the catch after the high dam was built, and from an average of 3,500 tons between 1958-64 before the dam was built to 9,000

¹⁶⁰ Christiane Leveque and Jacques Quensiere

tons in 1979 after completion of the dam. The Aswan High Dam was completed in 1970. This is quite surprising since the history of dams on downstream freshwater floodplain fishery production has been negative. As is seen below, it appears that the biggest impact of the Aswan High Dam is on the estuarine/marine sardine fishery (Section 7.8.7.6, Nile River, Aswan High Dam).

7.8.6.8 Inner/Central Delta, Niger River, Mali

The floodplains of the Central (Inner) Delta of the Niger River in Mali, linked historically to many of Sub-Saharan Africa's ancient civilizations (see Chapter 1), covers 20,000 km². As discussed in Chapter 2, it is a lifeline to local people in the production of fish, livestock and agriculture as are most floodplains in Africa. The Inner Delta contains 70% of the country's best agricultural land (for the most part irrigated), 50% of the nation's cattle and produces 80% of the fish caught in Mali. In short, the Central Delta is one of the main centers of production and export (mainly to Ghana and the Ivory Coast) of primary products from the Sahel (IFAD, 1999).

Drought and reduced flow affecting flood peaks have impacted on fish production and yield. In the case of the Central or Inner Delta of the Niger River, it appears that natural fluctuations in flow are still more relevant than modification of the downstream flow from dams (Laë & Mahé, 2002 *In: Läe, et al.*, 2003).

The fisheries of the Upper and Middle Niger River were deeply modified from 1950 to 1990 by two consecutive drought periods, dams and a rapid increase of fishing activities, readily observable in the Central Delta. From 1969-1986, floodplain areas contracted from 20,000 km² to 5,000 km², resulting in a decrease in annual yield/catch of fish from 90,000 metric tons to 45,000 metric tons (Läe, *et al.*, 2003). Furthermore, the Markala Dam, downstream of Bamako, Mali, built

in 1943 for the *Office du Niger* for irrigation (see Chapter 5, Section 5.12.1.3, Irrigation potential) and the Selengue Dam, a 400 km² hydro-electric dam upstream of Bamako, Mali, contribute to increase the effects of drought by further lowering the already reduced flood flows. As a result, the annual loss in total fish catches in the Central Delta is estimated to be 5,000 metric tons (Laë, 1992 *In: Läe, et al.*, 2003) attributable to these dams that contributes to the reduced catch of 45,000 metric tons.

The dams also affect upstream fish production by disrupting longitudinal migrations of fish.

“Another factor responsible for the decline in fish stocks is watershed degradation as a result of the combined effect of drought and human activities (itinerant agriculture, over-grazing, illegal cutting of wood). In Niger, this results in an increase in erosion and higher silt loadings, which, in turn, leads to formation of considerable sandbanks. Muddy habitats are destroyed, water volume is reduced and water quality deteriorates, as indicated by a high turbidity and low dissolved oxygen concentration” (*Läe, et al.*, 2003).

In the 1990s, migrant fishermen accounted for 59.2% of the Central Delta catch followed by sedentary fishermen (36.1%) and farmers/fishermen (4.7%). Seventy-six (76) species were registered in the fish landings, of which 17 species accounted for 85% of the fish landings. Fishing was mainly conducted by fixed and drift gill nets (40%), small traps (15.7%), cast nets (14.9%), multi-hook lines (10.6%) and large (7.8%) and small seines (4.3%) (*Läe, et al.*, 2003). Key species included Cichlidae with 26.6% of the catch, *Oreochromis niloticus* (10.2%), *Tilapia zilli* (8.3%), *Sarotherodon galilaeus* (6.2 %), *Oreochromis aureus* (1.9 %), and Clariidae with 18.7% of the landings (*Clarias anguillaris*) (*Läe, et al.*, 2003).

Fishing pressure has increased significantly over the years due to increases in the number of fishermen from 70,000 Bozos and Somonos in 1967 (Gallais, 1967 *In: Läe, et al., 2003*) to 80,000 in 1975 (Natural Resources And Breeding Ministry, 1975 *In: Läe, et al., 2003*), and 225,000 by 1987, of which 62,000 were active fishermen (Quensiére, 1988; Morand, Quensiére & Herry, 1990 both *In: Läe, et al., 2003*).

Fish yields have increased from 40 kg/ha in 1968 to 120 kg/ha in 1990 due to increased catches resulting from a shift to younger and smaller fish (e.g., opting for biomass versus size) from more intense fishing (Laë, 1995 *In: Läe, et al., 2003*), increased fishing pressure, an increase in fish concentration on reduced floodplains, an increase in intra and inter-specific fish competition and an increase in vulnerability to fishing equipment (Läe, *et al.*, 2003).

With the return of more regular flooding in the mid-1990s, annual yield/catch is averaging about 100,000 metric tons/year at the gross added value of about 30 billion CFA (US\$ 60 million/Euros 46 million)/year, the whole fishing networks contributing approximately 4.2 % to the gross domestic product (GDP) of Mali. The fishery employs 284,000 people, including 71,000 directly for production (Läe, *et al.*, 2003).

7.8.7 Dam Impacts on Estuarine and Marine Fisheries

Freshwater flows also help support marine fish production, as many marine fish spawn in the brackish waters of estuaries or deltas, whose salinities range between seawater (35 ppt.) and freshwater. A decrease in freshwater flow and in nutrients due to dam construction affects the nursery areas in a number of ways, including increasing salinity, allowing predatory marine fish to invade and reducing the available food supply (WCD, 2000). Linked to the aquatic food chain, mangrove ecosystems can also be adversely impacted.

7.8.7.1 Senegal River

Traditionally, before the construction of the Manantali and Diama Dams, with the receding waters of the rainy season, a salt wedge developed, moving up the river from the mouth as far as the Doué *Marigot* at Podor, 320 km upstream from the river mouth (Figure 7.4). The estuarine conditions created by this phenomenon were critical to fishes whose life cycles were tied to the salinity regime. These fishes included important species such as *Ethmalosa fimbriata* (African shad), *Tilapia guineensis*, *Sarotherodon melanotheron heudelotii*, *Mugil spp.*, and *Lisa spp.* The African shad, while only a small contributor to the commercial marine fishery, was important in the artisanal fishery at the mouth of the Senegal River. Invertebrates whose life cycles are tied to estuarine conditions include the crab, *Callinectes spp.*, and the shrimp, *Penaeus duorarum notialis* (*Penaeus notialis*) (GFCC, 1980a; 1980b).

The Manantali Dam affected these vital functions and reduced fishing significantly. Even fishing families are reported to eat imported fish now. The hydropower project will further impair fisheries in the floodplain and the coastal sea (Bosshard, 1999).

Fish production in the river and estuary has dropped by 90% (GEF, 2002). This implies that estuarine yields of fish after construction of the dams would have dropped to about 1,140 tons/year based on a pre-dam yield of 11,400 tons/year (GFCC, 1980b) (see Table 7.5).

This loss has been very extreme in the formerly estuarine part downstream of Diama and this has probably also impacted on marine fisheries through the loss of nursery functions for mullets (Mugilidae), shrimp (Penaeidae), shad (*Ethmalosa*

fimbriata) and other species having an obligatory estuarine life history stage (Hamerlynck, *et al.*, 2000).

According to Kloff (2002), the area most ignored for its need for fresh water is the area lying downstream of the Diama Dam. This former estuary lies outside the target area of the OMVS and is therefore more or less considered as a dumpsite for water that needs to be released during the wet season. Before the construction of this anti-salt barrage, the area was nevertheless of great economic importance as a nursery ground for numerous commercial marine fishes that spent part of their life cycle in the brackish estuary. Traditionally to spawn, mullets migrated at the beginning of each early dry season from the Banc d'Arguin National Park in the north of Mauritania to the Senegal River Delta (Kapetsky, 1981 *In:* Binet, LeReste & Diouf, 1994; Kloff, 2002) and to coastal lagoons (Kapetsky, 1981 *In:* Binet, *et al.*, 1994). In the sixties, abundant juvenile mullets were observed by a team of French and Mauritanian researchers at Rosso lying 80 km upstream of the present Diama Dam, which is 27 km upstream from St Louis near the mouth of the river – thus 107 km upstream from the river mouth. With the Diama Dam, the nursery area became greatly reduced due to the obstacle the dam posed for the migration of marine fishes and even worse the remaining area downstream of the dam deteriorated as a nursery due to a lack of fresh water and resulting hypersaline conditions (Kloff, 2002).

During the dry season, no freshwater was released by Diama into the former estuary, which became gradually hypersaline in the course of each dry season (Kloff, 2002). Juvenile fishes died due to the high salinity. Ten years after the construction of the Diama Dam, the mullet fishery sector - a multimillion-dollar business through the export of eggs (*poutargue*), a form of caviar, to Southern Europe – off the Atlantic coast of Mauritania completely collapsed. Although over-fishing is believed to be one of the major factors, the deterioration of the

former estuary is believed to have significantly contributed to the catastrophe (Kloff, 2002).

Kloff and Pieterse (2002) note that park rangers from the Diawling Park, south of Diama, are still observing several age groups of mullet downstream of the Diama Dam. These are, however, less abundant than in the sixties (Kloff, 2000). The mullet will never reach Rosso again because the dam is blocking their migration route, while the remaining habitat for mullet is not only much smaller but also of inferior quality compared to the pre-dam era, becoming hypersaline during the dry season. Today, young mullet cannot achieve adulthood and the stock at sea as a consequence is no longer significantly replenished.

According to Binet, *et al.* (1994), the anti-salt barrage, designed to preserve agricultural land from salty water and to make it irrigable, blocks the outflow of freshwater to the sea except during the heaviest flooding. The Diama also prevents migrations of anadromous¹⁶¹ species (e.g., mullet, shrimp and shad) and particularly the upstream movement of euryhaline¹⁶² species (e.g., shrimps, crabs and oysters). The freshwater species carried down toward the estuary by the floodwaters will no longer reach their destination and catadromous¹⁶³ species will be unable to spawn in the brackish waters. Major mortalities of migratory species are observed at certain times. However, the feared elimination of the bonga/shad (*Ethmalosa fimbriata*), *Callinectes* (crab) and the pink shrimp in the Senegal River estuary did not take place. Lastly, the irregular nature of water releases and hence of downstream phytoplankton surges have increased the “unpredictable” nature of this environment, favoring colonization by opportunistic species of low

¹⁶¹Anadromous fish species spend their adult lives in the sea but swim upriver to freshwater spawning grounds to reproduce

¹⁶²Euryhaline species live in a wide range of salinities as opposed to stenohaline species restricted to a narrow range of salinities

¹⁶³Catadromous fish species migrate from fresh water to saltwater to spawn

commercial value. Indeed, an increase in the relative numbers of *Tilapia* and mullet has been observed.

There seems to be some contradiction. However, this is not believed to be the case if one looks at what happened as a result of the 1970s drought in the creation of “natural” hypersaline conditions in the Siné Saloum and Casamance Estuaries (see Section 7.9.7.3, Hypersalinity, the evolution of mangroves in West Africa and its effects on fish stocks – case studies of the Casamance and Sine Saloum Estuaries). In the Siné Saloum Estuary, just north of the Gambia River and south of the Senegal River, where hypersaline conditions appeared to favor *Ethmalosa*, mullet and *Tilapia* over other species, there still was a major reduction in artisanal catches, including these species, during the drought period of the 1970s/early 1980s. Fish catches in the Department of Kaolack – Siné Saloum fell from a high of 4,000 metric tons in 1975 to a low of about 1,000 metric tons/year in the early 1980s. It should be noted that even though dominant in the catch, the *Ethmalosa* yields dropped from a high of 829 tons in 1975 to a low of 40-70 tons in the early 1980s in the Siné Saloum. Mugil species, likewise, while relatively speaking surviving the hypersaline conditions, dropped from a peak of 1,070 tons in 1975 to lows of 200-300 tons/year in the early 1980s in the Siné Saloum (DeGeorges, 1985). This also appeared to be the case for the Casamance Estuary just south of the Gambia River (DeGeorges, 1985) where the same three genera were dominant and where these species became dominant as one moved upstream towards more hypersaline waters, in places exceeding 170 ppt. (parts per thousand), the sea being 35 ppt. The Bas Delta study before the Diama Barrage, but impacted by the drought, showed similar results. With the drought and increasing hypersaline conditions, most species fell out of the catches, with the dominant ones being (DeGeorges, 1984):

- The African shad, *Ethmalosa fimbriata*
- *Tilapia/Sarotherodon*
- *Penaeus notialis*, etc – shrimp
- Two species of mullet (Mugilidae)

These are the same three genera/families of fish that became dominant in the Casamance and Sine Saloum.

7.8.7.2 Gambia River

There is a strong risk that a coastal/estuarine fishery yielding about 23,000 metric tons/year valued at Dalasis 66 million (US\$ 11 million)/year at mid-1980 conversion rates would be significantly degraded as an exploitable resource as a result of the Balingho Anti-Salinity Barrage. An estimate of 33 species of fish and shellfish, which comprise the majority of the fishery off the Gambia, are dependent, directly or indirectly, on the mangrove ecosystem and associated detrital food chain at critical stages of their life cycles (Table 7.8):

Table 7.8: Summary of fish and shellfish of the Gambia River whose life cycles are tied to estuarine mangrove ecosystems

Fishery	Percent Of Fishery By Weight Tied To Estuary/Mangrove	Percent Of Fishery By Value Tied To Estuary/Mangrove

Source: DeGeorges (1987d)

A major decline in these fisheries would be expected as a result of the Balingho Barrage. The Sine-Saloum Estuary in the Department of Kaolack, Senegal, and the Casamance Estuary in the Department of Sedhiou, areas affected by extreme hypersaline conditions - as is projected downstream if the Balingho Barrage is constructed - have seen a major reduction in annual yield/catch by as much as 75% and a major fall off in fish diversity (see Section 7.9.7.3, Hypersalinity, the evolution of mangroves in West Africa and its effects on fish stocks – case studies of the Casamance and Sine Saloum Estuaries) (DeGeorges, 1985; 1987d).

The species of fish affected by these hypersaline conditions in the Casamance and Sine-Saloum Estuaries are the same as most of the species currently important to the Gambian fisheries.

Binet, *et al.* (1994) predict that as a result of the Balingho Barrage, if the mangroves were lost as a source of the detrital food chain, plus as a nursery for shrimp, “the shrimp fishery can expect to see favorable initial trends (larger seaward-migrating shrimp) but the final result could be a reduction in the stock due to a shrinking adult habitat (river-exported muddy areas) and a drop in post-larval recruitment, as it seems unlikely that the post-larval stages could reach the river mouth unguided by a falling salinity gradient”. Van Maren (1985 *In:* DeGeorges, 1985) estimates a 10% decline of Gambia’s shrimp fishery, from the loss of mangroves upstream of the Balingho Barrage and, personally, the principal author believes this to be a low estimate, as this is in one of the more productive mangrove zones. It is estimated that an additional 40% of the annual shrimp harvest, in addition to oyster, crab and lobster production, could be lost below the barrage. The total loss of fresh and estuarine fish/shellfish above and below the barrage as a result of its impact on the environment was estimated at US\$ 1,400,000/year (University of Michigan, 1985a).

It is also unclear what the effects of hypersalinity and loss of estuarine habitat could have on offshore fish stocks, which have indirect ties to the estuary through the food chain.

Making exact quantitative predictions for each species is impossible due to the complexity of their life cycles, of which very little is known. However, based on a risk analysis of what is known, from the impacts of the Diama and Kheune¹⁶⁴ Barrages on the Senegal (DeGeorges, Sy & Ould Mbare, 1985) and the impacts of hypersaline conditions in pre-Diama in the Bas Delta Mauritania, Siné Saloum and Casamance Estuaries on fish diversity and yields, one would have to question the wisdom of the Balingho with regards to the fisheries.

The potential losses could never be made up with the projected 4-6,000 metric tons of fish that might come out of the Balingho Reservoir (see projections above in Table 7.3). Projected water quality problems with acidity, oxygen and salinity within the reservoir could drastically reduce these optimistic projections.

The University of Michigan (1985a) study estimates only a loss of 10% of the ocean fisheries and 30% of the estuarine fishery, even though they came up with a somewhat lower (than in Table 7.8) but still important estimate that 60% of the 1981 marine coastal catch was composed of species with their life cycles tied to the lower and upper estuaries. No explanation was given in either this report or the aquatic ecology report (University of Michigan, 1985b) at how they arrived at this estimate, but in the Water Resources Report they go on to admit that “the full extent of the impacts of the dam (Balingho) on the marine and estuarine fisheries remains to be determined”. The way forward is simple. After the catastrophic result from the Diama Anti-Salinity Barrage on the fisheries in nearby Senegal and the adverse impacts on the fisheries from hypersalinity in the Siné Saloum

¹⁶⁴ Year classes of fish as they moved up river to spawn were stopped by the barrage and then fished out with seines.

and Casamance caused by the drought, if there are other alternative development options without the Balingho Anti-Salinity Barrage, that is projected to have similar impacts, these should be considered. Why take the risk of destroying an entire ecosystem and food source?

Although exact change is difficult to quantify, this analysis led to the conclusion that if other development options existed that do not include the Balingho Anti-Salinity Barrage, but which permit the achievement of development goals, it would be best to abandon all options which contain Balingho in order to minimize the risk to the estuary and its natural resource base (University of Michigan, 1985b; Samba & DeGeorges, 1987a.) The University of Michigan (1985a) study found the Balingho to be neither economically nor environmentally viable.

7.8.7.3 Hypersalinity, the evolution of mangroves in West Africa and its effects on fish stocks – case studies of the Casamance and Siné Saloum Estuaries

This analysis can be used to obtain an idea of what might happen if the construction of the Balingho Barrage or similar anti-salinity barrages on other rivers, along with flow regulation from high dams significantly modifies estuarine conditions, resulting in reduced flushing, hypersalinity and mangrove dieback.

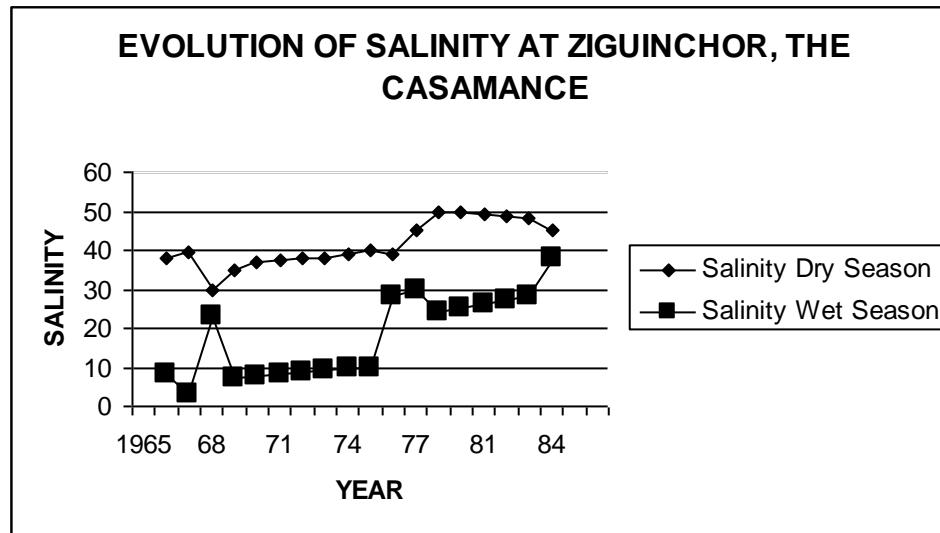

An important effect of decreased regional rainfall and decreased freshwater flushing in the 1970s and early 1980s was an increase in year-round salinities. Normal seawater contains a salinity of 35 ppt. The Casamance Estuary just south of the Gambia River and the Siné-Saloum Estuary, just north of the Gambia River have traditionally experienced the phenomenon of hypersalinity; salinities greater than 35 ppt.

For instance in the late 1960s, salinities as high as 93 ppt. at Fatick and 72 ppt. at Kaolack in the Siné Saloum were recorded (Bondy, 1968 *In:* DeGeorges, 1985). In the mid-1960s, salinities at Ziguinchor, the Casamance, climbed as high as 40 ppt. by the end of the dry season (LeReste & Odinetz, 1984 *In:* DeGeorges, 1985). These hypersalinities developed as a result of poor flushing by freshwater during the dry season combined with high evaporation.

Prior to the 1970s drought, yearly rainfall flushed these estuaries, resulting in a large dip in salinity during the rainy season.

Up until 1969, the estuary of the Casamance (just south of the Gambia River in Senegal), a long (230 km) and narrow (1 to 10 km wide) channel with a very low rate of flow (average 1968–1983: $2.7 \text{ m}^3/\text{s}$), was only very slightly hypersaline (40 ppt. in June, at 80 km from the mouth) (Binet, *et al.*, 1994) (Figure 7.3)

In the mid-1960s, the Casamance experienced salinities as low as 3 ppt. at Ziguinchor near the mouth of the Casamance. However, with increasing drought and possibly watershed degradation, this water body became increasingly saline (Figure 7.9).

Figure 7.9: Evolution of salinity at Ziguinchor, the Casamance, Senegal

During the same time, the Siné Saloum (an estuary just north of the Gambia River in Senegal), as measured at Foundioune, experienced salinities which fell as low as 15 ppt. (Figure 7.10).

Figure 7.10: Salinity profile versus rainfall, Foudiougne, Siné Saloum, Senegal, 1967-1968

During the drought years (1970s and early 1980s), there was very little flushing of these estuaries by fresh water during the rainy season. The most important flushing that occurred was tidal in nature. In the upper reaches of these estuaries, flushing was inadequate and evaporation rates were high. As a result, there was a tendency for the annual salinity curves to flatten out in the upper reaches of what has become in essence an extension of the ocean. Salinities had a tendency to remain high year round and in some instances to have increased (see Ziguinchor Graph, Figure 7.9 and Siné Saloum Graph Figure 7.11).

Extracted from: L'Homme (1980 *In: DeGeorges, 1987d*) with permission, IRD.

Figure 7.11: Salinity profile versus rainfall, Siné Saloum, Senegal, 1972-1973

In the Casamance, where salinity did not exceed 1 ppt. in 1969, it reached 70 ppt. in 1984. At the end of the 1986 dry season, salinity reached 170 ppt. at a location 220 km from the sea. During periods of drought, the Casamance Estuary exhibits a very slow “reverse estuarine” circulation which acts more as a confining mechanism than anything else (Binet, *et al.*, 1994).

Unfortunately, such records do not exist from the early part of the century for comparative purposes. However, the result of this long-term phenomenon has been to gradually reduce mangrove stands in West Africa over the last century. This can be tied to the drought and to the southward movement of the Sahel. The role of humans and their effects on land use and thus watersheds draining into these mangrove swamps and the contribution this may have on the regional degeneration of the mangroves from modification of local or basin-wide hydrology cannot be ignored (see below: Mangrove Dieback, Hypersalinity, Flow and the Shrimp Fishery).

What cannot be determined is to what degree the drought is cyclical and to what degree rains or drought may dominate over a reasonable planning horizon of the next 50 years. Proper planning may go a long way in minimizing the anthropogenic effects on this important resource/ecosystem.

It is known that in those estuaries where major mangrove dieback and hypersalinity have occurred in the Casamance and Siné-Saloum, there has been a major decrease in fish and shrimp yields and in species richness (see Tables 7.11 and 7.12, and Figure 7.12). In addition to a decline in the detrital food chain from the dieback of mangroves, so necessary for food production, the increasingly hypersaline year-round conditions physiologically stress the fish stocks.

The same genera and in many cases the same species of fish dropped off from what appear to be hypersaline conditions in both the Siné Saloum (Table 7.11) and the Casamance (Table 7.12), the former being documented temporally over a 13 year time frame spanning the last major drought. In the Department of Kaolack area of the Sine Saloum, this resulted in a diverse fish catch of 13 genera declining to three genera/families (Table 7.11):

- *Mugil spp.*
- *Tilapia/Sarotherodon spp.*
- *Ethmalosa fimbriata*

Figure 7.12: The relationship between the number of fish species and salinity in the Casamance as measured from January to March 1984

Fish catches in the Department of Kaolack – Siné Saloum fell from a high of about 4,000 metric tons in 1975 to a low of about 1,000 metric tons/year in the early 1980s. It should be noted that the *Ethmalosa* yields dropped from a high of 829 tons in 1975 to a low of 40-70 tons in the early 1980s. *Mugil* species, likewise, while relatively speaking surviving the hypersaline conditions, dropped from a peak of 1,070 tons in 1975 to lows of 200-300 tons/year in the early 1980s (Table 7.11).

In the Casamance, *Ethmalosa fimbriata* predominates downstream and is caught in waters as saline as 82 ppt. (Table 7.12). *Sarotherodon melanotheron* tolerates slightly higher salinity and predominates in assemblages further upstream. *Tilapia guineensis* has the same distribution but is less abundant, except far upstream where it is able to multiply rapidly (Binet, *et al.*, 1994). On the other hand, the *Ethmalosa* is capable of large-scale anadromous migration: in the Gambia, it goes as far as 200 km upstream when salt water flows in (Scheffers & Conand, 1976 In: Binet, *et al.*, 1994). Binet, *et al.* (1994) consider the *Ethmalosa* an

opportunistic fish capable of physiologically adapting to everything from hypersaline waters to estuarine/fresh water, with a wide-ranging and flexible behavior. This case study would seem to support this conclusion. Still, under hypersaline conditions yields of this species fall off!

The same three genera/families also became dominant in catches (Table 7.12) from the Department of Sedhiou, Casamance in the 1980s, going upstream from the mouth of the Casamance Estuary/River to Sedhiou (km 168) that in 1984 experienced hypersaline conditions of 82-83 ppt. (Albaret, 1984 *In: DeGeorges, 1987d*). As importantly, during this period, fish catches from this department declined from a high of 10,000 metric tons per year in the early 1970s (just before or at the beginning of the drought) to a low of 2-3,000 tons/year during the drought (DeGeorges, 1985 *In: DeGeorges, 1987d*). Likewise, the size of the fish greatly decreased in size in the Casamance during this same period where hypersalinity was a problem (Albaret, 1984 *In: DeGeorges, 1985*), very likely due to physiological stress affecting growth, fecundity and the inability of adult fish to withstand hypersaline conditions because of their decreased ability to adjust to osmotic stress compared to juveniles. This is an area requiring further study.

In the Casamance, Albaret (1984 *In: DeGeorges 1985*) also found a number of species to be reproductively “ripe” with eggs at relatively high salinities:

1. *Ethmalosa fimbriata*, ripe until 78 ppt.
2. *Gerres nigri* ripe until 66 ppt.
3. *Sarotherodon melanotheron* ripe at greater than 80 ppt.
4. *Liza grandisquamis* ripe until 54 ppt.
5. *Liza falcipinnis* one male out of a dozen found in sexually advanced state at 76 ppt., rest sexually arrested or beginning of maturation period

6. *Mugil cephalus* and *Mugil bananensis* at 76 ppt. sexually arrested or beginning of maturation period

There was no evidence of the relative success of larval or juvenile fish to survive under these hypersaline conditions (Albaret, 1984 *In: DeGeorges, 1985*), nor was there an indication of the effects of hypersaline conditions on fecundity (number of eggs produced by the estuarine fishes). The decreasing size of fish in the Casamance Estuary and the dominance of juvenile fish in the hypersaline waters of the Bas Delta, Mauritania (DeGeorges, 1984) implies that adult fish may not be able to physiologically tolerate such conditions. It would appear that adults of a number of species may be breeding in lower saline environments, while hypersaline zones are visited by the more physiologically adaptable juvenile fish for undetermined periods of time. Although not as clear, sampling of hypersaline ponds in the Aftout Es Sahel appeared to have resulted in a dominance of juvenile fish that may have their origin in waters of lower salinities (GFCC 1980a). Given the limited sampling times for these studies, this issue needed further study and research. If increasingly hypersaline waters results in a predominance of juvenile fish in the estuary, this could have grave economical implications for estuarine fisheries, since small fish tend to sell for a lower price per kilogram than large fish.

Preliminary indications in the Casamance were that a critical fall off of species occurred at hypersaline conditions between 56-66 ppt. (Table 7.12 and Figure 7.12). It is hypothesized that a critical fall off in biomass could be attained well before these salinities have been reached; once again, this would need to be studied.

According to Binet, *et al.* (1994), fish catches in the Casamance actually increased from 1965–1983 with the rise in salinity prior to collapsing in 1984. A

similar trend over time with increasing hypersaline conditions appears to be the case in the catch records shown for the Sine Saloum given in the Table 7.11, though exact salinities are not known.

An additional statistic that needed to be considered was provided by Dr. LeReste (*pers. comm. In: DeGeorges, 1985*)¹⁶⁶ of the *Centre de Recherche Océanographique Dakar/Tiaroye, Senegal* (CRODT)/*Institut Senegalais de Recherches Agricoles* (ISRA), which he obtained from the *Direction de Pêche et Océanographie Maritime* (DPOM). Since 1977, if not before, there was a gradual decline in the catch record of sole from the Casamance, primarily from the family Cynoglossidae (Table 7.13):

Between 1982 and 1985, sole had practically dropped out of the catch record near the ocean. Dr. LeReste attributed this to the increasing year-round hypersaline conditions (LeReste, *pers. comm. In: DeGeorges, 1985*). The Cynoglossidae have life cycles linked to estuarine conditions (see Table 7.9).

The risk to the estuarine fishery in the Gambia thus becomes obvious from these case studies: major declines in fish by species, abundance and likely yields.

Mangrove Dieback, Hypersalinity, Flow and the Shrimp Fishery

Pink shrimp, *Panaeus notialis*, spawn at sea. Post larvae are carried by the tidal currents to their estuarine nursery grounds. Dr. LeReste collected all known information from Senegal on the life history of this species (LeReste, *pers. comm.* In: DeGeorges, 1985). He found that in the estuary, shrimp preferred a range in salinity of between 25-55 ppt. and quiet waters of 30-36 cm/sec. Higher or lower saline conditions resulted in a rapid fall off in the size of shrimp. Stronger currents tended to push the shrimp from the estuary to the ocean. Weaker currents imply decreased freshwater flushing, which establishes conditions favorable for the development of hypersaline conditions and, in the extreme, decreased shrimp production.

According to LeReste, 1987 In: Binet, *et al.* (1994), “capture weight¹⁶⁷ is related to stock biomass and hence to the size of the migrating shrimp. Final shrimp growth size, however, depends on salinity and current speed, in accordance with the square of the salinity and in inverse ratio to the speed of the current”.

According to this model, size at migration peaks at a salinity of 29 ppt., (close to the osmotic sub-adult point of equilibrium), but shrimp size falls off strikingly at salinities below 10 ppt. or above 50 ppt. Within these boundaries, size depends primarily on current speed, which, in the Casamance, drops progressively upstream (Binet, *et al.*, 1994).

¹⁶⁷ Yield in tons

"Capture weight also depends on the numbers of shrimp caught and this, rather than spawning intensity, probably depends on the surface area of the zones favorable to post-larval ($5 < \text{Salinity} < 50$ ppt.) and sub-adult ($20 < \text{Salinity} < 50$ ppt.) growth" (Binet, *et al.*, 1994)

In the Casamance, which has been studied extensively by LeReste, the following was found (Figure 7.3):

- In the lower Casamance Estuary around Pt. St. Georges, while salinities are ideal, currents were too strong and shrimp never achieved very large size prior to migrating to sea.
- At Ziguinchor, salinities were ideal, currents reduced and shrimp achieved relatively large harvestable size both in the fall and in the spring.
- Further upriver, the size of the shrimp depended on rainfall:
 - In the fall, salinities may be ideal and currents low so as to permit an excellent harvest in October-November while later exhibiting excessive salinities that eliminate a good spring harvest (March-April).
 - High rainfall and strong currents may result in poor environmental conditions for a fall harvest, with appropriate salinities and currents being achieved in time for an excellent spring harvest.
 - Under ideal rainfall events, salinities and currents may be such as to permit both good fall and spring shrimp harvests.
 - Extremely low rainfall years may result in reduced currents and in excessively high year-round salinities resulting in a fall out of the shrimp fishery.

Hypersaline conditions and mangrove dieback also have had an effect on the shrimp fishery of the Casamance, shrimp using mangrove systems as nursery grounds. Between the beginning of the drought in the early 1970s and 1974, it was estimated that 25% of the mangroves in the Casamance Estuary died, this percentage increasing slightly each year thereafter until the preparation of the report in question (DeGeorges, 1985).

In 1984, the spring shrimp fishery collapsed, forcing the closure of fish processing plants in the Casamance (University of Michigan, 1985a; DeGeorges, 1987d). Thus, increased hypersalinity and predicted mangrove dieback from the Balingho Barrage on the Gambia River could adversely impact shrimp populations and yields.

Mangrove Oyster, Hypersalinity, Mangrove Dieoff and Emigration

In the Casamance, hypersaline conditions have also affected the mangrove oyster, so important to the artisanal fishery of the Gambia. According to Binet, *et al.* (1994),

“The harvest of mangrove oyster (*Crassostrea gasar*) is an ancient practice that is still very much alive in the Casamance (Cormier-Salem, 1987 In: Binet, *et al.*, 1994). There was a very active trade in dried oysters up to 1950. The harvest was particularly important during the drought years when it was impossible to grow rice. But the riverbank soil became increasingly permeated by acid sulphates and salts and the groundwater became very salty. Upriver from Ziguinchor, the mangroves are now nothing more than dead wood. There was a spectacular drop in the *Rhizophora mangle* zone in favor of a degraded mangrove or *Sesuvium* carpet. The ‘tannes’¹⁶⁸ have risen by 73% to the detriment of the waters and the mangrove. The habitat favorable to oysters has shrunk substantially. Last of all, spawning and growth are also adversely

¹⁶⁸Tannes are bare saline and acidic soils, normally just inland from mangroves where no plant life can grow.

affected by the salinity. The drought-related drop in agricultural activities is no longer offset by the oyster harvest, which was traditionally a women's job, and this has produced rural emigration. Only the resumption of a favorable rainfall pattern could reverse this trend”.

Likewise, “in the Casamance, all the freshwater fish still found in the Gambia estuary until recent times have disappeared” (Albarete, 1987 *In: Binet, et al.*, 1994).

The above factors must be taken into account in assessing the possible effects of dam development on the Gambia River Basin’s fishery resources. This is especially true for any activity, which could result in a major modification of the estuarine ecosystem, such as the Balingho Anti-Salinity Barrage, and modification of downstream hydrology by high dams.

The above changes which could impact on the mangroves and the fisheries of the Gambia would also result in secondary impacts such as the use of mangroves as a renewable resource for wood and energy supplies, the availability of fresh water in mangrove zones for swamp culture of rice, the availability of fish as economic and nutritional resources for the region, the availability of fish for piscivorous birds and mangrove leaf fall as a source of food for the manatee (Powell, 1984).

In closing this session, it must be understood that in undertaking an environmental assessment, one is not conducting primary research but in many cases drawing on the best available current data. This data must be synthesized, assessed for what it is worth, and then a risk or opportunity-cost analysis must be undertaken based on best available data. This will help show what alternative will allow politicians and decision-makers to best achieve their goals, while still minimizing the adverse impacts to a particular area of concern. The analysis in these sections was an attempt to undertake such an exercise.

7.8.7.4 Dam impacts Zambezi River Delta estuarine fishery

Almost half of the shrimp species caught are of the species *Penaeus indicus*, which have a life cycle of one year. Spawning takes place at sea, but the larvae and juveniles require brackish water as nursery areas and must migrate against the current to reach the protected mangrove swamps. Because shrimp are inefficient swimmers, low dry season flows enable them to migrate inshore on tidal currents. High flood season flows, in turn, lower the salinity in the mangrove swamps and trigger juveniles to move from the mangrove zone to the ocean to reproduce. Flood flows also spread nutrient-rich river water along the coastal bank to stimulate shrimp recruitment (Beilfuss & dos Santos, 2001).

“With the closing of Kariba Dam in 1959 and Cahora Bassa Dam in 1974, nearly 90% of the Zambezi catchment has become regulated and the natural flood cycles of the Lower Zambezi River are now a phenomenon of the past. Flooding events in the Lower Zambezi, when they occur, are now dependent upon local rainfall-runoff within the Lower Zambezi catchment or unplanned (possibly catastrophic) water releases from the upstream dams” (Beilfuss, *et al.*, 2002).

“The prawn fishery off the delta coast, which began in 1965, is one of the most important sources of foreign currency in Mozambique, employing many people near the coastal cities of Chinde and Quelimane. The catch rate of the shrimp has been decreasing at a rapid rate since the early 1980s, largely due to reduced Zambezi flooding and increased dry season flows” (Beilfuss, *et al.*, 2002.).

“Catches declined from 10,000–12,000 tons in 1974-76 to 8,000 tons in 1983 and 7,900 tons in 1998 and were comprised of 3 species making up the following percentages of catch; comprised of three species – *Penaeus indicus* (48%), *Metapenaeus monoceros* (42%) and *Penaeus monodon* (10%)” (UTIP, 2002).

In the Zambezi Delta, the adverse impact of modified seasonal flows on local shrimp fisheries has been estimated at minus -\$10 million (WCD, 2000) to minus 10-20 million/year (Hoguane, 1997 *In:* Beilfuss & dos Santos, 2001). It is predicted that catch rates would increase by 20% with increased flood flows (Gammelsrod, 1992 *In:* Beilfuss & dos Santos, 2001; UTIP, 2002) from December to March (UTIP, 2002) and decreased dry season flows (Gammelsrod, 1992 *In:* Beilfuss & dos Santos, 2001) or 1,500 tons/year valued at US\$ 9 million (Euros 10 million) (UTIP, 2002).

At the same time,

“Over the past three decades, riverine and near-shore coastal fisheries have replaced the floodplain fishery in the Delta. Fishermen use canoes and nets or lines. They concentrate in small fishing camps along the riverbanks, producing fresh, dried, or smoked fish. Only about 17% (one-sixth) of the households in the Marromeu area sell fish during most years. The catch-per-unit-effort in the main stem Zambezi is low due to high dry season flows, and most of the fishing camps are now found in the coastal waters of Chinde district” (Beilfuss, *et al.*, 2002).

Further upstream, some Cyprinid fish species have been observed unsuccessfully attempting to climb up a low dam wall on the Manyame River near the Seke-Doma Township when the reservoir spills. Adults of all four species of eels, *Anguilla bengalensis labiata*, *A. bicolor bicolor*, *A. marmorata* and *A. mossambica*, known to occur in Zimbabwe, migrate to the sea for breeding. The young eels, called elvers, migrate upstream into rivers where they spend the next 10 - 20 years before returning to the Indian Ocean for breeding. It appears that they are able to find a way through the Cahora Bassa Dam. It was argued that the Kariba Dam was an impenetrable barrier for eel migrations, but evidence suggested that eels were still able to move upstream across the dam wall, as eels younger than the dam were observed in Lake Kariba and further upstream. It is

not known whether the African mottled eel, *A. bengalensis labiata*, manages to overcome the Cahora Bassa Dam in its up- and downstream migrations (WCD, 1999).

7.8.7.5 Volt River, Akosombo Dam/Volta Reservoir, Ghana

Filling the Akosombo Reservoir behind the dam took several years, resulting in a heavily reduced seaward flow with infiltration and evaporation reducing the flow still further. In the Volta Estuary and adjacent lagoons, the quantity and quality of the freshwater changed considerably. Shrimp and oyster production ceased in the lagoons and a record low in shrimp production was recorded (Mensah, 1979 *In: Binet, et al.*, 1994).

7.8.7.6 Nile River, Aswan High Dam

Prior to the Aswan High Dam (pre-1970), nutrients carried into the Mediterranean during the flood season resulted in large plankton blooms. This supported a large sardine fishery accounting for 30-40% of the annual Egyptian marine fishery yield. With the Aswan High Dam, and the elimination of the annual flood, the sardine fishery fell from 18,000 tons to less than 1,000 tons. The catch has since risen to a few thousand tons attributed to improved catch technologies, not necessarily a return in production. The shrimp yields at the mouth of the Nile also decreased by 67% with the elimination of nutrient supplies. Landings of other fish were 77% below pre-dam levels (McCully, 2001). Kapetsky and Petr (1984) estimate a decline in the sardine fishery as a result of the Aswan High Dam, their proportion in catches falling from 37% to 9%. General fish landings in the Mediterranean fell from a high of 38,000 tons in 1962 to 7,000 tons in 1979 or 81% below pre-dam highs, but then appeared to recover to some degree.

7.8.7 Dam Impacts on Forests

Impacts on forests occur from those lost within the inundation zones of reservoirs and those lost downstream from modified flood regimes. Of significant consequence are impacts on mangrove ecosystems, which are linked to a detrital food chain necessary to sustain many rich fisheries in the tropics. They also serve as habitat for unique species such as manatee and dugong.

7.8.8.1 Senegal River

The Senegal River's Manantali Reservoir destroyed 120 km² (12,000 ha) of forest within the inundation zone (Bossard, 1999). The GFCC environmental assessment predicted more than three times this amount of forest being lost; about 7 km² (700 ha) of productive fringe forest would be lost along the Bafing River and 429 km² (42,900 ha) of less productive open forest would be permanently lost, both from inundation behind the Manantali Dam (GFCC, 1980d).

The downstream impact from reduced flooding by the Manantali was projected to result in a loss of 76 km² (7,600 ha) of the remaining 379 km² (37,900 ha) of occasionally flooded *gonakié* forests and 10 km² (1,000 ha) of yearly flooded *gonakié* forests (GFCC, 1980e). *Gonakié* forests are composed almost exclusively of *Acacia nilotica* and are commercially valuable with a production rate of 1.43 m³/ha/year (20 cubic feet/acre/year) serving as firewood, charcoal and food (e.g., seed pods and seedlings) for livestock and wildlife, among others (GFCC, 1980e). The forests have died from lack of water (on the higher grounds) or water logging (in the low lying areas). Many have also been destroyed as a measure to control nesting sites of granivorous bird pests. Finally, many have been cut and sold for charcoal production because they were standing on land that would possibly be converted into paddy fields. There is a major adverse impact on

pasture/forage quality from wind and rain erosion associated with reduced forest cover (Hamerlynck, *et al.*, 2000).

Following the closure of the Diama Dam, mass mortality of the remaining mangrove stands occurred, especially in the late 80s and early 90s when strong tides that used to ride up the river were deflected from the dam and flooded the low lying Ntiallakh basin. As these floods tend to occur at the end of the dry season, water downstream of the dam was strongly hypersaline and vast areas were covered with a thick salt crust after the waters retreated. The impact on *Sporobolus robustus* stands, a perennial grass used in mat weaving, which, incidentally was the main source of income of the local women, was also devastating (Hamerlynck, *et al.*, 2000).

7.8.8.2 Gambia River

Closely tied to aquatic production and dominating the ecology of Gambia's Estuary are its mangrove swamps. There are an estimated 623.6 km² (62,360 ha) of mangroves comprising six species. Where floodplains tended to dominate in the Senegal River Basin's aquatic and terrestrial production, the extensive mangrove systems dominate aquatic production in the Gambia River Basin. Mangroves can be found from the mouth until 215 km upriver near Jarreng (Samba & DeGeorges, 1987b). This system is dominated by two species, *Rhizophora racemosa* and *Avicennia africana* (Snedaker, 1984; Twilley, 1985; Huygen, 1978 both *In:* DeGeorges, 1987d):

- *Rhizophora racemosa* is considered a pioneer species, colonizing recently deposited alluvial soils. *Rhizophora racemosa* stands greater than 20 meters high are found on the North Bank, just below Balingho at 119 km (mile 74) to a little above Dankunku Island at 167 km (mile 104). Stands

decrease up- and downstream from these two points due to the *Rhizophora*'s decreasing ability to stand increasingly more saline waters and its inability to out-compete other plants in increasingly fresh waters. It is the *Rhizophora racemosa*, which accumulates the pyrites that result in the production of potentially acid sulphate soils. *Rhizophora* forests are among the most productive woodlands in the Gambia River Basin with a growth potential of 70-210 m³/ha/year as a harvestable renewable resource.

- *Avicennia africana* is normally found behind the *Rhizophora* going inland perpendicular from the shoreline on higher elevation, higher saline soils. *Avicennia* is more salt tolerant than *Rhizophora*, being able to excrete salt from its leaves. Progressing further inland, soils become even more saline and more acidic where no plant can grow, this area being called *TannVif*. As the soil evolves going even further inland, it increases in pH and decreases in salinity to the point where tolerant plants such as *Sesuvium portulacastrum* invade bare tann soils. Eventually, the soils become more sufficiently evolved to permit rice culture. *Avicennia* are among the least productive forests in the Gambia River Basin with a growth potential of 5-10 m³/ha/year as a harvestable renewable resource. This evolution of soils and vegetation can be considered typical of mangroves in West Africa.

Other less important species include *Rhizophora harrisoni*, *R. mangle*, *Laguncularia racemosa* and *Avicennia nitida*. Mangrove ecosystems play a multifaceted role in the natural and human-made environments of the Gambia River Basin, but are adversely impacted by regional and local watershed degradation linked to humans and their livestock (Figure 7.13).

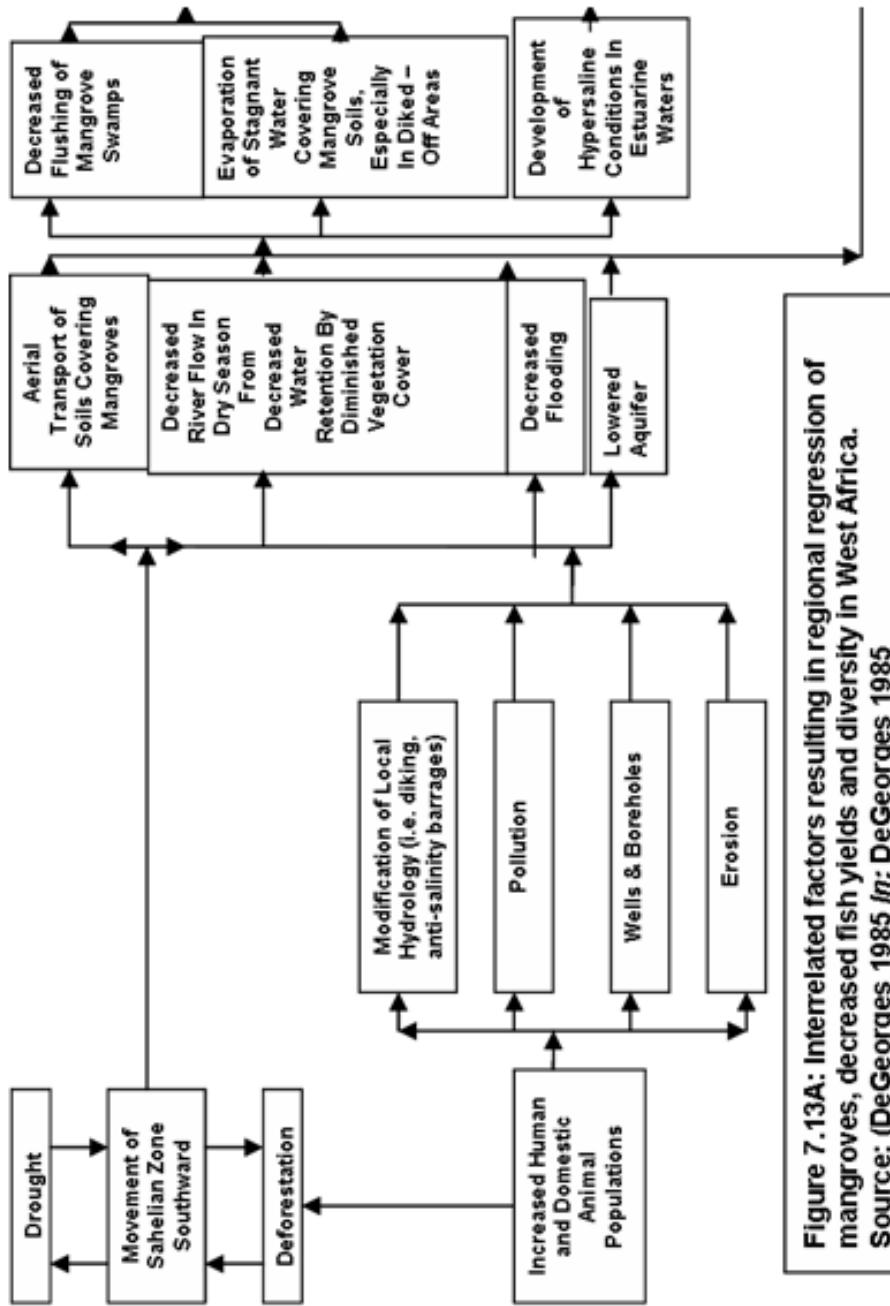

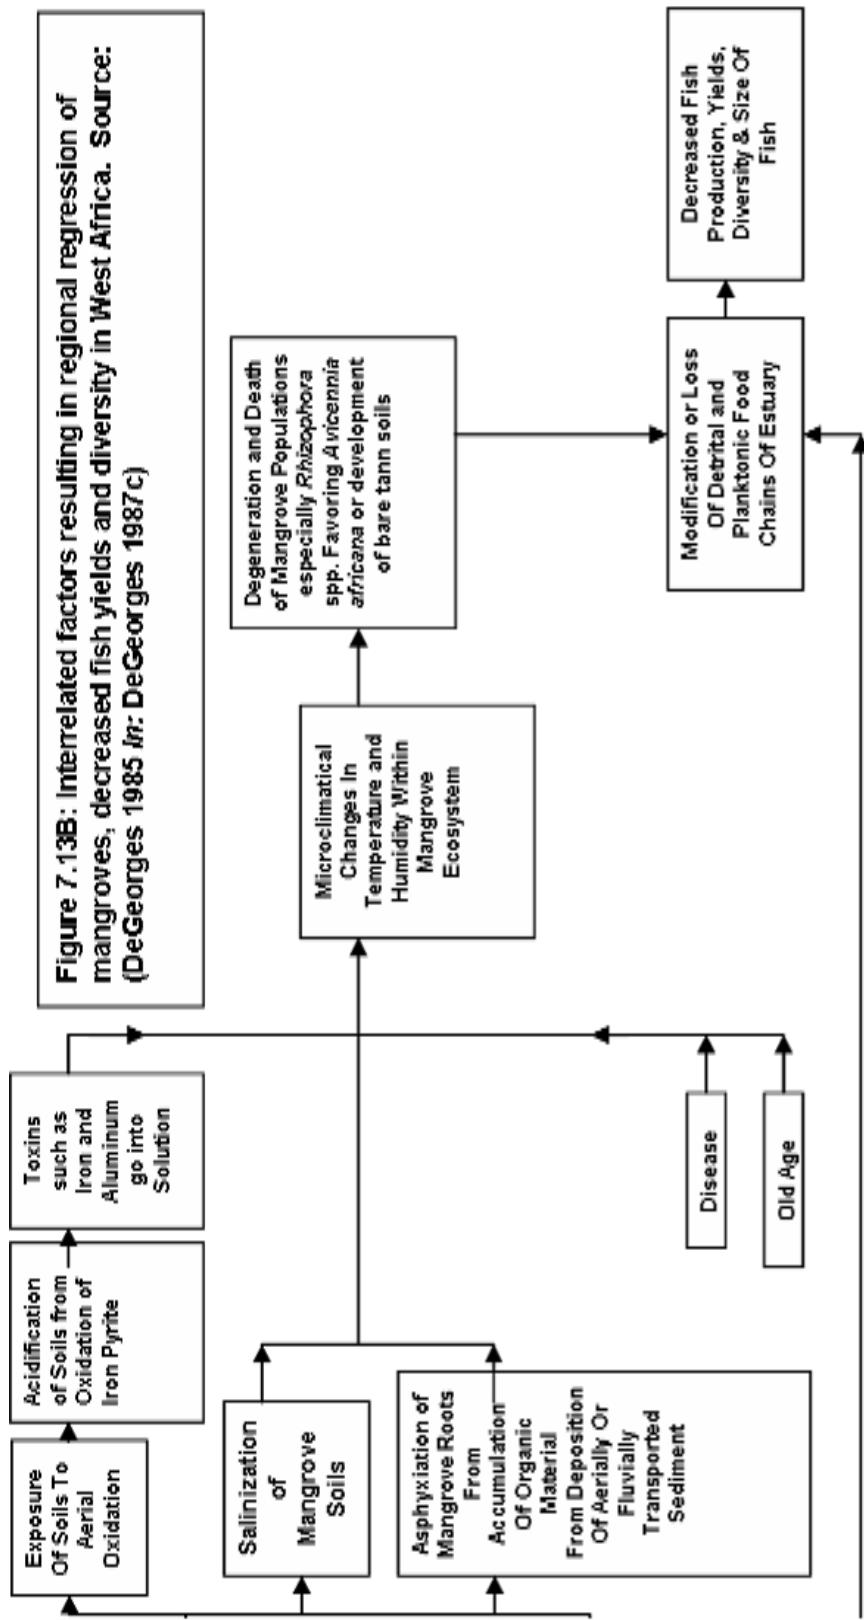

Figure 7.13A: Interrelated factors resulting in regional regression of mangroves, decreased fish yields and diversity in West Africa.
Source: (DeGeorges 1985 *In: DeGeorges 1985*)

Aquatic production in the Gambia River Estuary depends heavily on the detrital chain set up by leaf and litter fall originating from the mangrove ecosystem. This has been substantiated by in-situ measurements of primary productivity, which, although limited, indicate that the entire river system with the exception of the Lower Estuary tends to be heterotrophic, that is primary production in the food chain is driven by detrital material as opposed to autotrophic production by phytoplankton (DeGeorges, 1987d).

The main impacts on forests were projected to be on mangroves lying up- and downstream of the Balingho Anti-Salinity Barrage. These losses could not be mitigated. The extensive mangrove forests risked being degraded as a renewable resource. A standing crop of about 872,300 m³ of potential timber totaling 79 km² (7,911 ha) of mangroves would be permanently lost from inundation and the creation of a freshwater reservoir (Rodriguez 1985 *In:* Samba & DeGeorges, 1987a; 1987b). This is estimated to be 12% of the total mangrove forest in the basin (University of Michigan, 1985a). It was projected that there would also be a major dieback and inland shift of mangroves over an estimated minimum of 30 to a maximum of 130 kilometers downstream of the dam.

The most productive forests in the basin, *Rhizophora*, would be replaced by the more salt tolerant *Avicennia*, among the least productive forests in the basin (Snedaker, 1984; Huygen, 1978 both *In:* Samba & DeGeorges, 1987a; 1987b). The loss and/or species shift in mangroves, declining detrital food chain and deteriorated habitat as a result of the Balingho Barrage would adversely impact the estuarine and marine fish production of the 31 species of fish noted above (Section 7.8.7.2, Gambia River).

The loss of mangrove habitat would greatly accelerate bank erosion (Snedaker, 1984 *In:* Samba & DeGeorges, 1987a; 1987b) and accelerate the process of

sedimentation in the Balingho Reservoir as well as the Port of Banjul. This could cost millions of dollars a year in dredging to maintain the reservoir and the port. Tidal amplitude was projected to increase between 10 and 20% below the barrage because of reflection of tidal waves off the barrage face (Harza, 1985 *In:* University of Michigan, 1985b).

7.8.8.3 Kiambere Dam, Kenya, Tana River

The Bura irrigation scheme was designed for 35,000 settlers on 14,170 ha (35,000 acres) growing cotton and staple corps in the Somali border district. After seven years, 2,632 ha (6,500 acres) were planted and only 2,000 families had moved in while capital costs escalated from US\$ 98.4 million in 1977 to US\$ 110 million (Rosenblum & Williamson, 1987).

While Bura irrigation managers knew that settlers would need fuel to meet their cooking needs, the project did not address the question. No woodlots were planted early on to provide fuel wood. Settlers had no choice but to plunder the riverine forest, the only green strip of land in this arid region. The forests and wildlife protection component of the Bura irrigation project never got off the ground and deforestation ensued. Both the dam and irrigation scheme were funded by the World Bank (Horta, 1994).

7.8.8.4 Masinga Dam, Tana River, Kenya

Key water catchment ecosystems - among them Keiyo-Turkwell, Mt Elgon Forest and the Kinale-Aberdare-Mt Kenya forest belt - are under assault from loggers and speculators. The Kenya Wildlife Service (KWS) warns that the country risks losing all its forest cover in the first half of this century. The Kenya Forest Working Group, a group of government and non-governmental bodies interested

in forest issues, says that any country with less than a 10% (tenth) of its land under forest is environmentally unstable. By 1988, “the siltation rate has more than tripled to 10 million tons a year, while the reservoir storage capacity has gone down by 6%”, in the words of Dr Hirji Rafik, a senior research specialist, World Bank (Opala, 2001). The design sediment load into the reservoir was estimated as 3 million m³/yr, while later estimates show an increase to 11 million m³/yr, nearly four times the design capacity of the reservoir. Increase in soil erosion on farmlands, access tracks and roads, coupled with clearing of forests without concomitant soil erosion control measures point to the causes of an increased rate of sedimentation (Bobotti, 2000).

7.8.9 Dam Impacts on Livestock and Wildlife.

The most significant impact on livestock and wildlife from dam construction in Africa tends to be the loss of critical dry season grazing land along floodplains. In certain cases, where a high dam inundates major wildlife habitat, this has forced the displacement of game, placing additional pressures on the remaining habitat and often causing conflict with humans.

7.8.9.1 Senegal River

Very little of Sub-Saharan Africa’s revered mega-fauna is left along the Senegal River Valley, while remnant populations exist in the headwaters of Mali. However, the world renowned Djoudj National Bird Sanctuary, a UNESCO (United Nations Educational, Scientific And Cultural Organization) World Heritage Site, is a major wintering ground for an estimated 3 million birds coming from Europe and Asia and along with resident birds comprises about 300 identified species (UNEP-WCMC, 2002). Certainly, the major loss of floodplains

has had a long-term adverse impact on migratory birds, though no quantitative data is presented.

Le Houerou and Hoste (1977 *In: GFCC*, 1980f) found that in the Sahel, the area required to support one tropical livestock unit (TLU) of 250 kg (consuming 6.25 kg dry matter/day or 1,400 forage units and 95 kg total digestable protein/year; cattle, camel, horse and donkey = 0.85 TLU and sheep/goats = 0.14 TLU) (GFCC, 1980f) was:

- 12.72 ha in areas with <250 mm rainfall.
- 6.35 ha with 251-500 mm rainfall.
- 3.17 ha with 501-1,000 mm rainfall

At the time of the GFCC (1980f) study, the load was 8.96 ha/TLU in Senegal, with no figures for Mali or Mauritania.

Along the Senegal River and throughout the Sahel, nomadic pastoralists and their livestock disperse from the floodplains during the rainy season and return during the dry season. During the rainy season (June/July through about October), the herds move north on the Mauritanian side and south into the interior on the Senegalese side of the river to exploit the highly nutritious pastures and to avoid the disease vectors in the flooded valleys. The timing of their return to the floodplains depends on the intensity and extent of the year's rainfall and therefore of the available pasture outside of the wetlands. In bad rainfall years, the floodplains are virtually the only refuge, allowing the animals to survive until the next rains (Hamerlynck, *et al.*, 2000).

Reduced flooding and dikes for irrigation have reduced traditional grazing lands from 80,000 ha to 4,000 ha in the valley (GEF, 2002). Using the above estimate of 8.96 ha/TLU, this means that there would be a reduction from 8,928 TLUs to

446 TLU on the floodplains at a minimum. The impact is likely greater if, in fact, with the Manantali, the average annual flood of 459,000-549,000 ha (GFCC, 1980b; 1980d) lasting 5 months (GFCC, 1980h) had been reduced to about 340,000 ha (see Table 7.5) amounting to a decline in grazing land of between 119,000 and 209,000 ha, or 190,000 ha flood under full development amounting to a decline in grazing land of between 269,000 – 359,000 ha (see Table 7.5). The reality is that today the annual average flood of about 77,000 – 104,000 ha (average about 82,600 ha) for about 2 months (see Section 7.10.7.1, Senegal River) results in a decline in grazing land of from 355,000 - 472,000 ha or more depending how much of the flood recession agricultural residue is made available to livestock after the harvest. The carrying capacity of these floodplains is likely much higher than the average ha/TLU given above so that the impacts would be much more dramatic as likely 100s of 1000s of livestock concentrate along the river during the dry season to take advantage of this extremely productive environment. If an estimated 300,000 head of cattle concentrate on the Gambia River Floodplains (Carney, 1984 *In:* Samba & DeGeorges, 1987a; 1987b) that total 158,000 ha (DeGeorges, 1987d) and that are orders of magnitude smaller than those of the Senegal River then two to three times this number might use the Senegal River Floodplains during the dry season. In the Senegal portion of the Senegal River Basin alone, GFCC (1980f) estimate livestock loading in the pre-dam period to range between 566,000 to 742,000 TLUs ranging over 6,649,500 ha, which was believed to be conservative. By converting all livestock to TLUs, GFCC (1980d) estimated about 2,066,000 TLUs for the entire basin. A large portion of this livestock would likely end up along the floodplains of the Senegal River during the dry season, while some might migrate southwards feeding on crop residue in farming areas.

Many riparian species depend on shallow floodplain aquifers that are recharged during regular flood events (WCD, 2000). In the *Bas* Delta of Mauritania,

traditional pasture included the grasses such as *Sporobolus robustus*, as well as pasturage in inundation zones consisting of *Echinochloa colona*, *Oryza barthii*, and *Dactyloctenium aegyptium*. *Acacia nilotica* was present in low-lying areas and inter-dune depressions. *Acacia tortilis* was found on interior dunes. Decreased flooding from the Manantali Dam as well as the droughts of the 1980s resulted in a rising saltwater groundwater table, and subsequent soil salinization. This has resulted in severely degraded pasturage throughout the Delta and the Senegal Valley. A dike on the right bank, Mauritanian side of the Lower Delta had a similar impact. Salt tolerant species of lower nutritional quality replaced these grasses and trees. The *Avicennia germinans* mangroves and plains *Sporobolus robustus* just about disappeared (GREZOH, 2000).

Gambia River

Wildlife, protected by international and national conservation, and its habitat would be threatened by the proposed Balingho Barrage. Species potentially affected by the loss of habitat, especially mangroves include:

<u>Species</u>	<u>IUCN/ESA STATUS¹⁶⁹</u>	<u>CITES¹⁷⁰</u>
West African Manatee (<i>Trichechus senegalensis</i>)	Vulnerable/Threatened	Appendix II
Sitatunga (<i>Tragelaphus spekii gratus</i>)	Low Risk/-	-
African Dwarf Crocodile (<i>Osteolaemus tetraspis</i>)	Vulnerable/Endangered	Appendix I
Nile Crocodile (<i>Crocodylus niloticus</i>)	-/Endangered	Appendix I ¹⁷¹
African Slender-Snouted Crocodile (<i>Crocodylus cataphractus</i>)	Data Deficient (DD)/Endangered	Appendix I
Sousa Dolphin (<i>Sousa teuszii</i>)	Data Deficient (DD)/-	Appendix I

¹⁶⁹ IUCN (International Union For the Conservation of Nature) from IUCN (2004); ESA (1999). See Chapter 10, Figure 10.7: IUCN species threat categorization and U.S. Endangered Species Act (ESA) (ESA, 1999) and see Chapter 10, Section 10.7, ENDANGERED SPECIES ACT OF THE USA, IMPEDIMENT TO AFRICAN CONSERVATION.

¹⁷⁰ CITES (2005); UNEP-WCMC (2005), see Chapter 10, Section 10.3, CITES for definition of Appendix I, II, III.

¹⁷¹ Except Botswana, Ethiopia, Kenya, Madagascar, Malawi, Mozambique, Namibia, South Africa, Uganda, Tanzania (subject to export quota of no more than 1,600 wild specimens including ranched specimens), Zimbabwe and Zambia in Appendix II (CITES, 2005; UNEP-WCMC, 2005).

The major impact of the dam options on the natural environment in the Upper River comes from adverse (-), long-term irreversible effects of the Kekreti Reservoir on the Niokolo Koba Park and surrounding habitat. It was projected that 77 km² (7,700 ha) of the Niokolo Koba Park would be inundated. This is less than 0.1% of the park (University of Michigan, 1985a). However, the Niokolo Koba Park represents a major source of tourism revenue for the region and is the major refuge for some of the last populations of large mammals remaining in West Africa. The park is classified as an IUCN “Man and the Biosphere Reserve” and as a UNESCO “World Heritage Area”. Among other species, it contains:

<u>Species</u>	<u>IUCN/ESA Status</u>	<u>CITES</u>
Chimpanzee (<i>Pan troglodytes</i>)	Endangered/Endangered	Appendix I
Wild Hunting Dog (<i>Lycaon pictus</i>)	Endangered/Endangered	-
Lion (<i>Panthera leo</i>)	Vulnerable/-	Appendix II
Leopard, (<i>Panthera pardus</i>)	-/Endangered ¹⁷²	Appendix 1
Elephant (<i>Loxodonta africana</i>)	Vulnerable/Threatened	Appendix I ¹⁷³
Western Race, Lord Derby		
Eland (<i>Taurotragus derbianus derbianus</i>)	Endangered/-	-
African Dwarf Crocodile (<i>Osteolaemus tetraspis</i>)	Vulnerable/Endangered	Appendix I
Nile Crocodile (<i>Crocodylus niloticus</i>)	-/Threatened	Appendix I
African Slender Snouted Crocodile (<i>Crocodylus cataphractus</i>)	Data Deficient (DD)/Endangered	Appendix I

At the time (early 1980s), there were only about 25-50 elephant remaining in Niokolo Koba. In 2004, the numbers were so low that translocating elephant from Burkina Faso has been considered. Likewise, this pocket of the Western race of the Lord Derby eland is in dire need of protection. The Niokolo Koba Park, with its extension into Guinea-Conakry (Parc de Badiar) and the adjacent Falémé River Basin, serves as important habitat for large antelope including the Lord Derby eland (*Taurotragus derbianus derbianus*), western roan (*antelope cheval* or *koba* - *Hippotragus equinus koba*), sing-sing waterbuck (*kob defassa* -

¹⁷² “Endangered” in Africa except “Threatened” south of and including, the following countries: Gabon, Congo, Zaire, Uganda, Kenya (ESA, 1999).

¹⁷³ Botswana, South Africa, Namibia and Zimbabwe, Appendix II, rest Appendix I (CITES, 2005; UNEP-WCMC, 2005)

Kobus defassa unctuosus/Kobus defassa defassa/Kobus ellipsiprymnus unctuosus), western hartebeest (*bubale* - *Alcelaphus buselaphus major*), cob du buffon (*Kobus kob kob*) and Harnessed bushbuck (*guib harnaché* - *Tragelaphus scriptus scriptus*), as well as the West African savanna buffalo (*Syncerus caffer planiceros*), hippopotamus (*Hippopotamus amphibius*), lion (*Panthera leo*), red river hog (*Potomochoerus porcus*), wild dog (*Lycaon pictus*) and honey badger (*ratel* - *Mellivora capensis*).

Outside of the Niokolo Koba/Badiar/Falémé complex, wildlife is on the verge of extinction in this part of West Africa, due to the historical past of mono-culture economies “peanuts” supplying cooking oil to colonial mother countries (e.g., France and Britain). This destroyed much of the wildlife and its habitat. Continued encroachment by human settlement and associated charcoal production, unregulated hunting, over-grazing and unsustainable itinerant slash and burn agricultural associated with reduced fallow are resulting in soil mining and massive habitat losses. Sadly to say, due to over-population and antiquated laws disenfranchising rural people from their wildlife and forests, sleeping sickness and the tsetse fly, are “the finger in the dike, holding back the flood” and even this is precarious since the N’Dama cow is trypano-tolerant (tolerant to sleeping sickness carried by the tsetse fly) (Van den Ende, 1984), allowing human habitation to encroach within this last refuge for wildlife in West Africa. Construction of a hard top road from Tambacounda through Niokola Koba via Kedougou and then through the *Zone d'intérêt Cynégétique de la Falémé* (hunting block) in the late 1980s/early 1990s would also certainly have encouraged human/livestock encroachment and poaching. Concern was also raised that in-migration of people and livestock to the reservoir zone to take advantage of fishing and other economic opportunities would risk increased human/wildlife conflicts from predation, poaching and from disease. It is believed that Niokolo Koba’s status as a national park and as a tourist destination would be seriously

compromised by the construction of the Kekreti Dam and Reservoir. With or without a dam, at the onset of the 21st century the only hope for this last refuge for Africa's mega-fauna in West Africa is community empowerment over these resources along the lines of "*gestion des terroirs*" principles which are discussed in Chapter 9 on Community-Based Natural Resource Management (CBNRM) (see Chapter 9, Section 9.8.9, *Gestion des Terroirs*, West Africa).

Further downstream in The Gambia, regardless of whether a piece of floodplain is rainfed or riverfed, irrigated or kept in tidal swamp, it would be necessary to integrate the estimated 300,000 head of cattle that use the floodplains as dry season forage areas into the management of planned agricultural development (Carney, 1984 *In:* Samba & DeGeorges, 1987a; 1987b). This would be necessary both above and below Kuntaur. Any scenario with the Balingho Barrage would result in 40,550 ha of dry season grazing area being permanently lost on the North Bank, Lower River and McCarthy Island divisions as a result of inundation by the Balingho Barrage's reservoir (Carney, 1984 *In:* Samba & DeGeorges, 1987b) out of a total floodplain estimate of 158,000 ha (DeGeorges, 1987d).

7.8.9.3 Zambezi River

Kariba Dam, Reservoir Area

Three major game reserves were created to absorb wildlife displaced by the Kariba Lake (Thomson, *pers. comm.*):

- The Matusadona Game Reserve (now national park) makes up about 25% of the Kariba shoreline;
- The Chete Game Reserve and Sijarira Forest take up 50% of the Binga District of the Kariba shoreline; and
- The Chizazira Game Reserve.

The Chete and Chizazira shorelines are rocky and deep, unsuitable for both fishing and agriculture and not even that good for wildlife. Neither Chete nor Chizazira have much tourist value. Matusadona had good land and could be considered for settlement, but comprised only about 12% of the entire southern Kariba shoreline. It has become a tourist destination, albeit a small one (Thomson, *pers. comm.*).

The actual “Operation Noah” was more of a publicity stunt than an effective conservation undertaking to “save wildlife” that might be lost from inundation by the Kariba Reservoir (Thomson, *pers. comm.*). Over a five-year period, about 6,000 animals were rescued (Nhamo, 1999; Tumbare, 2000). According to Ron Thomson (*pers. comm.*; Thomson, 1997), of this only about 2,000 could be considered game, and this mostly consisted of impala. There were 20-30 black rhino caught of which nine black rhino were sent to the Hwange National Park and the remainder released on the mainland and a few sable recovered, but the majority were medium to small animals like kudu, bushbuck, impala, waterbuck,

monitor lizards, baboon and monkeys, mongoose, etc. This was mainly wildlife trapped on “islands” created by the rising waters of the reservoir. Most of the recovered wildlife was released into the newly settled Ba-Tonga areas, and/or released along the riverbanks and wandered into their resettlement areas only to be poached!

The majority of wildlife moved off into the interior on its own, becoming “super-saturated” as it competed for food, territory and space with wildlife already existing in the areas of refuge (Thomson, *pers. comm.*; Thomson, 1997; 2003).

Kariba Dam, Downstream, Zambezi River

The flood magnitude of the Zambezi River was reduced by 24% due to the Kariba Dam, resulting in the reduction of flooding of the Mana Pools Floodplain (WCD, 1999; Tumbare, 2000). Riverine vegetation was replaced by more dry land vegetation in those areas normally kept wet by discharge overspill during flooding (WCD, 1999). Normally the rains in Zimbabwe arrive in November-December within the immediate Kariba Watershed in Zimbabwe and Zambia. The flood peaks in April with waters originating out of the Angolan Highlands, the Victoria Falls being at their peak at this time (Beilfuss & dos Santos, 2001; Thomson, *pers comm.*). Throughout eons of time, the downstream wildlife developed its life cycle, as did the people, around this cyclical flooding. Most wildlife along the river reproduced at the low point in the Zambezi water regime in September and October and/or was somehow dependent on traditional low flow regimes for survival, for example:

- Wildlife that lays eggs in riverbanks such as crocodile, monitor lizards, bee-eaters, plovers and king fishers (Thomson, *pers. comm.*);

- Wildlife that nests on sand banks such as the African skimmer (*Rhynchos flavirostris*) (Thomson, *pers. comm.*); and
- Wildlife that nests in reed beds such as weaver birds (Thomson, *pers. comm.*).

Also,

- The breeding cycles of many species of water birds, including threatened species such as Pel's fishing owl (*Scotopelia peli*), the eastern white pelican (*Pelecanus onocrotalus*), wattled crane (*Bugeranus carunculatus*), black stork (*Ciconia nigra*), and African skimmer (*Rhynchos flavirostris*) are triggered by the annual inundation and draw down of floodwaters (Beilfuss & dos Santos, 2001).
- Several species of wading birds, including the openbilled storks (*Anastomus lamelligerus*), depend on the annual minimum flows for freshwater snails and mussels on the exposed shifting sandbars of the Lower Zambezi during the dry season (Beilfuss & Bento, 1997 *In:* Beilfuss & dos Santos, 2001). Any further stabilization of the Zambezi flow regime will greatly diminish the availability of sandbar habitats, threatening one of the largest populations of openbilled storks reported in Africa (Beilfuss & dos Santos, 2001).

With the coming of the rains in November and December, the Kariba Reservoir fills rapidly. The sluice gates were not designed to be able to discharge this quantity of water in so short a time. In anticipation of this sudden rise in water level and in order to avoid breaching and possibly breaking the dam face, waters are released early in September and October (Thomson, *pers. comm.*). According to Beilfuss and dos Santos (2001),

“the magnitude of monthly flows is sharply reduced during the peak-flooding season, including a 41% reduction in the mean monthly flow in April and 36% reduction in March...translating to a dramatic decrease in the inundated area of floodplains below Kariba Gorge, including the Mana Pools National Park”, while “average dry season flows have more than tripled, from 255 m³/s to 812 m³/s in October, changing the dry season character of the Zambezi River from a meandering sandbank river to a single down-cut channel”.

Both Thomson (*pers. comm.*) and Beilfuss and dos Santos (2001) agree that these modified, and one can say irregular and inappropriate, flows during the dry season have an adverse impact on the reproductive cycles and/or food supplies and thus the population status of the above species along the main channel of the Zambezi. Since this wildlife had been evolutionally programmed, each year this wildlife sets about breeding and each year humans wipe out nesting sites, eggs and food supplies with these artificially high flows. These species are replaced to some degree with wildlife breeding along feeder-rivers and streams that are not impacted by these floods (Thomson, *pers. comm.*).

Cahora Bassa Reservoir Area

The reservoir area supported a rich diversity and density of animals, including eland, bush pigs, buffalos, elephant, and rhinoceros. Large herds of animals were swept away as the lake rose and others starved on small islets in the middle of the newly formed lake. Some migrated out of the region, and others retreated to the reservoir shoreline and surrounding escarpment. In recent years, many of the remaining mammals have disappeared from the Cahora Bassa lakeshore due to over-hunting, although significant numbers remain in the Magoe and Cahora Bassa Districts on the southwestern shore of the reservoir (Beilfuss, 2001).

Wildlife and Livestock Impacts in the Zambezi Delta from the Cahora Bassa Dam and the Kariba Dam

Recent research in the Zambezi Delta suggests that wattled cranes (*Bugeranus carunculatus*) have abandoned most of the floodplain, due to erratic flooding patterns, in favor of floodplains adjacent to the Cheringoma Escarpment, which still receives unregulated floodwaters (Beilfuss & dos Santos, 2001). With similar impacts from irregular wet and dry season flows from dam releases, the causes for this movement are discussed in the following case study of the Kafue Flats, Zambia, also the home of the wattled crane (Beilfuss & dos Santos, 2001; Kamwenesche & Beilfuss, 2002).

The 6,880 km² (688,000 ha) Marromeu Complex consists of the Buffalo Reserve established in the 1950s and four surrounding hunting blocks established in the 1960s (*coutadas* 10, 11, 12, 14) on the south bank, made up of floodplain grasslands, deepwater swamps and mangrove forests (Beilfuss & dos Santos, 2001). The Marromeu Swamps contained one of the highest populations of buffalo in Africa. Prior to the construction of the Kariba Dam, peak floods spread over a mosaic of vegetation communities in the 12,000 km² (1,200,000 ha) Zambezi Delta, one of the largest wetland systems in Southern Africa. Floodplain grasslands were inundated with floodwaters for up to nine months of the year and many areas were saturated throughout the dry season (Beilfuss, Moore, Bento & Dutton, 2001).

The Kariba, Kafue and then Cahora Bassa Dams have fundamentally altered the very large floodplain in the Zambezi Delta. With the great reduction in flooding, dry season forage was lost for both livestock and wildlife.

With the closing of the Kariba Dam in 1959 and the Cahora Bassa Dam in 1974, nearly 90% of the Zambezi catchment has become regulated and the natural flood cycles of the Lower Zambezi River are now a phenomenon of the past. The Kariba controls 40% of the Zambezi Basin runoff. Flooding in the delta is now dependent on local rainfall-runoff within the Lower Zambezi catchment or unplanned (possibly catastrophic) water releases from the upstream dams (e.g., 2001 floods). These hydrological changes are further exacerbated by the construction of dikes along the Lower Zambezi for agriculture, trains and road networks that prevent medium sized floods up to 13,000 m³/s from inundating the south bank floodplains (Beilfuss, *et al.*, 2001).

“Much of the Lower Zambezi Valley is well suited for livestock production, and livestock grazing activity was closely linked to Zambezi flood patterns. Livestock were typically herded along the riverbanks, where they found the best pasture and water supply. The availability of good quality pasture in the late dry season was especially important, and depended on prolonged flooding during the wet season” (Beilfuss, *et al.*, 2002).

Migratory and local movements of wild ungulates in the delta were opportunistic responses to the availability of different vegetation communities allowing ungulates to meet their year-round life requirements through rotational grazing in response to natural flood cycles (Beilfuss & dos Santos, 2001). Herbivory is an integral part of the succession dynamics of floodplain systems, exerting selective pressure on the delta grassland composition. Many herbivores have co-evolved with plants, acting as dispersers and influencing plant regeneration patterns. Coarse grass (bulk) feeders, especially buffalo and elephant, graze down rank pastures and enhance grazing conditions for the medium to short grass feeders such as waterbuck and zebra. The mulch of grass flattened by large herds of buffalo and elephant also enables greater penetration of rain and results in better primary production of floodplain grasses. Following the ebb line is a zone of

changing width of moist soil (depending on micro relief at each water level), supporting a green flush of vegetation that gradually dries out on its upper margins. Grazing herds follow the green zone and vacate browning lands. During these annual migrations, herbivores provide opportunities for plant regeneration by removing large quantities of emergent vegetation and trampling seed into soils, while browsers remove woody growth at the floodplain periphery (Beilfuss, *et al.*, 2001).

Primarily from the reduction in flooding, relatively drought-tolerant grassland species have displaced flood-tolerant species in the broad alluvial floodplain and saline grassland species have displaced freshwater species on the coastal plain. Coastal mangrove has been replaced by saline grassland at the tidal margin. Of critical importance for large herbivores is the Tussock grass habitat, reduced by 23% over the last 40 years, a major source of food in the wet season grazing areas for buffalo, zebra, waterbuck, etc. migrating from the more deeply inundated floodplains (Beilfuss, *et al.*, 2001).

Soft-leaved grasses and sedges in the swamps, preferentially grazed on by buffalo and waterbuck until floods limited access, have been reduced by 6% over the last 20 years (Beilfuss, *et al.*, 2001). Woody vegetation and thickets invade grasslands and drought resistant less nutritious grassland species replace stressed wetland species of higher nutrient content. Similar patterns have been shown for the Kafue Flats and middle Zambezi Floodplains following river regulation. Cape buffalo are highly susceptible to starvation and high mortality when their pastures dry out early, especially when uncontrolled fires sweep across the delta. Hippo and waterbuck are also vulnerable to poor forage conditions in floodplains (Beilfuss & dos Santos, 2001). This also allows easy access to the game by local hunters, “poachers”, a major problem in the Marromeu Buffalo Reserve and surrounding hunting blocks (Wicker, *pers. comm.*).

“The total area of perennially wet grassland, permanent deepwater swamp, and coastal mangrove is now about 2,600 km² (260,000 ha), or 22% of the total delta area. There has been an 18% reduction in permanently flooded areas since 1960, and a 12% reduction in perennially wet grassland. The average duration of inundation in the hydromorphic vertisols along the western edge of the floodplain has decreased from 4-6 months per year in the past to 2-3 months per year today. These changes suggest that moisture conditions have become limiting in many areas of the floodplain. Most of the delta grasslands now burn during the dry season, and deciduous Acacia savanna covers much of the higher delta plain” (Beilfuss & dos Santos, 2001).

These changes would have begun in 1974 and 1975 with the filling of the reservoir.

It is estimated that between 1976 and 1979, 12,400 buffalo were cropped (Anderson, Dutton, Goodman & Souto, 1990). A sustainable game cropping operation was initiated, with 30,000 animals harvested between 1978 and 1985, but wildlife populations remained strong (Bindernagel, 1980; Tello, 1986 both *In: Beilfuss, et al., 2001*) (Table 7.14). However, civil war and anarchy ended sustainable management of this area. Dutton, Ribaune, Jujumen, Carvalho and Pingo (2001) show buffalo populations for 1994 as 2,346, in 1999 as 2,000, in 2000 as 5,125 and in 2001 as 3,056. The total ungulate population went from 81,570 in 1979 to 4,354 in 2001, a decline of 95%.

Anderson, *et al.* (1990) place the cause for major reduction of wildlife on uncontrolled hunting with military weapons during the protracted civil war. Also, over a period of only seven years – five at the end of the civil war and the first two years following the cease-fire in 1990 – wildlife populations were decimated by illegal commercial meat hunting – (Beilfuss, *et al.*, 2001).

Table 7.14: Wildlife population reduction between 1968 and 1990 Zambezi Delta Complex

Species	1968	1977	1978	1979	1988	1990	% Reduction, 1978-1990
Buffalo	20,000	55,595 (45,000)*	43,992	30,394	11,575	3,696	91.5
Waterbuck	40,300	36,380	46,227	45,653	6,455	4,490	90
Elephant	257	331	361	373	1,554	326	1
Zebra	673	1,340	2,120	2,720	---	1,205	43
Hippo	250	2,820	1,010	1,770	-----	260	74

Prepared by principal author

Beilfuss, *et al.* (2001) also note:

- An increase in human population in order to escape the war.
- Increased desiccation of the swamps associated with the dams.
- Increased human access and increased burning of the grasslands.

All of these factors are believed to have been significant in impacting on the wildlife in this complex. *Coutada* (hunting block) operators in the delta now complain that the foraging quality of the delta grasses has decreased. Similarly, in the Mana Pools, between the Kariba and Cahora Bassa Dams, the frequency of perennial grasses declined with the lack of Zambezi flooding (Beilfuss, *et al.*, 2001). The decline in buffalo numbers in 2001 is said to be from drowning, mostly of young, from the 2001 flood, which was of exceptional magnitude (Dutton, *et al.*, 2001).

The elimination of hippos has probably contributed to the drying out of abandoned alluvial channels and loss of open water areas, the wallowing activities

of hippo being vital in maintaining open water conditions in the many small ponds and distributary channels of the delta (Tinley, 1977 *In: Beilfuss, et al.*, 2000). These changes have been exacerbated by drier conditions across the delta from reduced flooding.

Likewise, the reduction in wildlife grazing pressure has also contributed to the increased extent of wildfires during the dry season. In the 1960s and 1970s, intense grazing by wildlife created a mosaic pattern of grazed and ungrazed grasses (Tinley 1977; Tello & Dutton 1979 both *In: Beilfuss, et al.*, 2000), creating natural firebreaks. With the reduction in wildlife populations, vast expanses of ungrazed floodplain have created highly combustible vegetation at the end of the dry season. Coupled with the general desiccation of the floodplain, wildfires now spread unchecked across extensive areas. Nearly 95% of the delta burns during the dry season and fires penetrate deep into the formerly inundated floodplains. Only the permanently flooded areas remain unburned.

Because of the desiccation of the floodplains, wildlife has unlimited access to the delta floodplain throughout the year, since there are no floods to drive them to the upland margin. The floodplain grasslands are now highly susceptible to over-grazing because they are no longer rested during the flood season each year. The decreased grazing pressure from reduced wildlife numbers has likely prevented further degradation of the floodplain grasslands. As wildlife populations slowly recover in the delta, unless the hydrological conditions in the delta improve, careful management will be required to prevent the widespread degradation of the floodplain grasslands due to over-grazing (Beilfuss, Dutton & Moore, 2000; Beilfuss *et al.*, 2001)

There is a widespread opinion among *coutada* operators and wildlife biologists that the delta can no longer support the large herbivore concentrations it supported

prior to the 1980s (Beilfuss, *et al.*, 2001), implying that this is due to impacts primarily from reduced flooding. Some operators, as Toni Wicker (Wicker, *pers. comm.*) believe that continued poaching into the 21st century is the main cause for the failure of buffalo and other wildlife populations to recover. Anderson, *et al.* (1990) recommend the consideration of artificial flooding. The questions that need answering are, “Why is the population of buffalo in the Marromeu Complex stagnant at around 4-6,000, along with apparently stagnant numbers of other ungulates? What percentage of the failure of the buffalo population to increase exponentially by 400-600 buffalo a year is from continued poaching by a disenfranchised and impoverished community of about 20,000 people surrounding the area, versus the change in habitat from the loss of flooding”? This needs careful investigation followed up by mitigation. In 2005, a meeting took place in Maputo to discuss the possibility of artificial flooding.

7.8.9.4 Kafue, Zambia

The 6,500 km² floodplain ecosystem of the Kafue River, Zambia, the Kafue Flats, was once one of the richest wildlife habitats in the world. Normally, the surrounding grasslands become regularly flooded as part of the natural water cycle of the Kafue Flats. However, the flood regime of the Kafue Flats has been modified by two dams (WWF/Netherlands, 2002), which have disrupted the reproductive cycles of many fish species and therefore populations of piscivorous birds (see Figure 7.5, Kafue River Dams). Reduced flooding is also believed to be negatively affecting wildlife, by prolonging the period of nutritional stress and reducing the area of optimum low flood grazing. Wildlife and fisheries are the principal resources in the Kafue Flats, but poaching and over-fishing are now threatening these (Kamwenesche *et al.*, 2002). Productive grasses have been replaced by aquatic plants in those areas now permanently inundated by

reservoirs. Populations of zebra, wildebeest, sitatunga and the endemic Kafue Lechwe have been greatly reduced (WWF/Netherlands, 2002).

“The most important herbivore of the Central African floodplain is the lechwe antelope, *Kobus leche*. Three races have been described. The Red Lechwe, *Kobus leche leche* is the most widespread of the three species, occurring in the upper drainage of the Zambezi, Kafue, Okavango Delta and the Congo River systems. The other two sub-species occur only in Zambia. The Black Lechwe, *Kobus leche smithemani* is endemic to the Bangweulu Basin and the Kafue Lechwe, *Kobus leche kafuensis* is endemic to the Kafue flats” (Kamwenesche, *et al.*, 2002).

Lechwe is an old Bantu name for antelope. Since the construction of hydroelectric dams in the Kafue Flats in the 1970s, it is thought that the population of Kafue Lechwe has been more than halved: from approximately 100,000 in the 1970s to fewer than 40,000 in 2001 (WWF/Netherlands, 2002). Kamwenesche, *et al.* (2002) provide the following statistics (Table 7.15).

Table 7.15: Decline of Kafue Lechwe population over time

YEAR	ESTIMATE	STANDARD ERROR
1970 (April)	95,040	37,638
1970 (October)	95,075	11,415
1971	94,212	15,958
1972	93,159	21,891
1973	109,612	7,640
1975	80,774	9,860
1981	45,867	6,145
1982	41,345	4,932
1983	41,155	6,247
1988	65,018	7,497
1989	47,145	5,345
1990	44,538	3,723
1999	45,000	-
2002	42,000	-

Source: Kamwenesche, *et al.* (2002) with permission, Dr. Richard Beilfuss, Carr Foundation-Mozambique & Saving Crane Foundation.

Changes in the flooding regime have affected the Kafue Lechwe in several ways (DFID, 2002):

- In the western part of the Flats the decrease in forage grasses and increase in woody and weedy herbaceous plants has reduced lechwe grazing.
- In the eastern part of the Flats the increased area of permanent inundation has reduced the habitat suitable for lechwe from 1,078 km² in 1970 to 930 km² post dam construction. This reduction in suitable habitat means that the lechwe continuously forage in a limited array of vegetation communities, which increases the risk of range deterioration.
- The lechwe breeding system has been adversely affected by changes in flooding patterns.

Acreman *et al.* (2000) also tend to believe that modified flooding has negatively impacted lechwe populations, although poaching is also a factor. They fail to state, however, which they consider most important. Poaching, infectious diseases, grazing pressures, traditional hunting practices, human presence in the area, and small-scale agricultural practices are also major factors responsible for the decline (Siamudaala, Muma, Munang'andu & Mulumba, 2005 *In:* Osofsky, Cleaveland, Karesh, Kock, Nyhus, Starr & Yang, 2005). The population should increase exponentially by at least 10% per annum (Kamwenesche, *et al.*, 2002). If the current population is about 40,000-45,000, it should increase by 4,000 animals per annum, assuming natural morality. However, the population has not increased significantly since the early 1980s, suggesting that 4,000 or more lechwe fail are being killed each year through hunting, habitat loss, or not appearing due to reduced fecundity. Since the limits for legal offtake during this period have been maintained below 2-4% of the population (fewer than 800 animals) and since

there is no evidence of large-scale mortality from disease, one can only conclude that the major causes for the lack of population growth are poaching or reduced fecundity. Poaching is particularly a problem during the period of high flood levels, when lechwe are forced to migrate to the floodplain periphery close to the villages in Muchabi and other areas in the Blue Lagoon (Timberlake, 2000; Kamwenesche, *et al.*, 2002; DFID, 2002). Based on official statistics, Siamudaala, *et al.*, 2005 (*In: Osofsky, et al.*, 2005) estimate that between 1995 and 1999, 4,679 lechwe were legally harvested of which 4,353 lechwe (93%) were hunted for meat and 326 (7%) for trophies, valued at US\$ 47,459 and US\$ 60,315/year respectively. This gives an average annual sustainable harvest rate of 936 animals: 871 for meat and 65 for trophies. It also amounts to an average of 47.7 tons/year of meat consumed by an estimated 39,780 people. Poaching for the bushmeat trade is believed to account for another 50% of the official quota or about 468 lechwe harvested/year, giving a total of 1,404 lechwe harvested/year or about 3-3.5% of the current population.

The principal author personally hunted a lechwe with professional hunter Rory Gellatly¹⁷⁴ in the late 1990s. He observed pickups loaded with up to five or more lechwe each; some of trophy quality taken by local hunters who are said to chase the herds with their vehicles. The posted game guard asked the principal author to shoot a couple of extra ones for him and his friends, which was refused.

The modified flood regime is also believed to be contributing to a reduction in the lechwe population since it is very important to its life cycle.

“The most important factor found to affect the distribution of females and calves was the distance from the waterline, followed by vegetation community selection, followed by preference for shorter grass. Mothers retreat to secluded areas with tall grass

¹⁷⁴ Rory Gellatly, P.O. Box 300050, Lusaka, Zambia, Member Professional Hunters Association of Zambia (PHAZ).

where they give birth to their young, and the highest densities of Lechwe occur in the Vossia-Echinocloa floodplain grasslands. All of these conditions are affected by the flooding regime, and the cumulative effects of Itezhitezhi Dam and Kafue Gorge Dam may be a reduction in the extent and quality of available habitat on the floodplain" (Kamwenesche, *et al.*, 2002).

Zonation of key vegetation of the floodplains has been described as follows by Ackerman, *et al.* (2000):

Permanent Swamp:

Vossia cuspidata,
Echinochloa scabra + Cyperus papyrus,
Leersia hexandra + Echinochloa
pyramidalis

Deep Flooded Grassland Long Flood

Oryza perennis + Echinochloa
pyramidalis

Deep Flooded Grassland Short Flood

Leersia hexandra + Acroceras macrum
+ Paspalum commersonii

Shallow Flooded Grassland Long Flood

Setaria avettiae + Vetiveria nigritania

Shallow Flooded Grassland Short Flood

Cynodon dactylon
Setaria sphacelata + Themeda triandra

Floodplain Margins

Hyparrhenia rufa + Setaria sphacelata
+ Panicum coloratum

A total of 275 buffalo were observed: a herd of 240 buffalo was observed on the floodplain of the Blue Lagoon National Park and two herds of 20 and 15 in the Kafue game management area. This is a substantial increase over the 1999 survey, which recorded 188. Historically, buffalo were very common on the Kafue Flats, but have been subject to heavy hunting pressure (Kamwenesche, *et al.*, 2002). The total population of hippos on the flats is unknown. The 1990 estimate was more than 80 (Kamwenesche, *et al.*, 2002). As it is difficult to observe, the exact number of sitatunga in the Kafue Flats is unknown, though numbers are believed

to have significantly declined over the past decades from habitat loss and poaching (WWF/Netherlands, 2002). Although past surveys suggest that sitatunga were once common on the Kafue Flats, the current population is probably less than 100 individuals, (Kamwenesche, *et al.*, 2002). Historical accounts suggest there were many thousands of zebra on the Kafue Flats earlier in the century, often in very large aggregations of up to 1,000 or more. Today, estimates are somewhere between 500 and 2,000 (Kamwenesche, *et al.*, 2002).

More than 450 bird species occur in the Kafue Flats, some all year round and some as season migrants. The Kafue Flats lie along a major migration route. Palearctic migrants¹⁷⁵, along with seasonal migrants from the rest of Africa, frequent the area. White pelican (*Pelecanus onocrotalus*), pink-backed pelican (*Pelecanus rufescens*), open-bill storks (*Anastomus lamelligerus*), Goliath herons (*Ardea goliath*) and spur-winged geese (*Plectropterus gambensis*) occur here, alongside what is thought to be Africa's largest population of the highly endangered wattled crane (*Bugeranus carunculatus*) that is highly reliant on wetlands for breeding and are easily disturbed. With fewer than 10,000 remaining, the wattled crane is Africa's rarest crane, its habitat impacted by dams and decreased flooding on the Kafue River (WWF/Netherlands 2002). A recent coordinated international survey effort in Botswana, Mozambique, South Africa, Tanzania and Zambia suggests that the population may even be less than 7,000, with no more than 4,000 wattled cranes in Zambia (Kamwenesche & Beilfuss, 2002). Concern also exists that modified flood regimes are endangering the wattled crane in the Zambezi Delta (Beilfuss & dos Santos, 2001) – see 7.8.9.3 under Zambezi Delta.

In an undisturbed floodplain, the breeding cycle of wattled cranes is intimately linked to the natural flood cycles. Wattled crane pairs are “triggered” to nest as

¹⁷⁵ Biogeographic region that includes Europe, Africa north of the Sahara and Asia north of the Himalaya Mountains

floodwaters begin receding after peak flooding. Nesting in deep open water after the major flood rise and crest ensures that nests will be protected from predators and wildfires, but will not be drowned by further rising floodwaters. As floodwaters slowly recede, wattled cranes raise their single chick on the pulse of exposed plant and insect life, especially tubers of the *Eleocharis* spike rushes. When flooding patterns are erratic or mistimed, wattled crane pairs may not be induced by hydrologic conditions to initiate nesting. Where nesting is attempted, unanticipated water level rises can drown nests and food sources. Rapid water level drawdown in the floodplains may expose nests to wildfires and predators and limit food availability. Prior to dam construction on the Kafue River, 40% of wattled crane pairs attempted to breed in a year of normal flooding conditions, while only 3% of all pairs bred in a year of negligible flooding conditions due to drought (Beifuss & dos Santos, 2001; Kamwenesche & Beifuss, 2002).

When the Itezhitezhi Dam altered the hydrological regime of the Kafue Flats, Konrad (1981 *In:* Kamwenesche & Beifuss, 2002) predicted a dramatic restriction in wattled crane nesting sites and feeding area. Despite these concerns, there have been no detailed studies of wattled cranes and wetland biodiversity in the Kafue Flats during the past 25 years of Kafue River regulation. A 2001 survey counted a total of 756 birds, giving an estimate of 967 wattled cranes for the sampled area. One flock of 460 birds was observed in the Blue Lagoon National Park. Other large flocks included groups of 35, 19, 17 and 14 birds, mostly on the north bank. Although it is possible that the estimates from the 1970s and 1980s were too high—based on difficulties in extrapolating from large flocks—it seems very likely that there has been a substantial decline in the population of wattled cranes on the flats over the past 20 years, perhaps most significantly between the 1980s and 1990s. It is unknown whether this decline represents a real decrease in the global wattled crane population or a shift in seasonal or annual distribution. The peak breeding months of April/May and August coincide with high levels of

human activity such as livestock grazing from May-July when upland fodder is limited. Uncontrolled fires were observed in several areas. There is a need to better understand how sudden flood releases from the Itezhitezhi Dam affect the feeding and nesting activities of wattled cranes (Kamwenesche & Beifuss, 2002).

Domestic livestock, particularly cattle, are widespread on the Kafue Flats, with several thousands in the Kafue game management area. Conflicts between cattle grazing and wildlife utilization, especially lechwe and zebra, are a major conservation issue for the Kafue Flats. The question of competition for food and transmission of diseases between lechwe and livestock has also been raised (Kamwenesche, *et al.*, 2002).

7.8.9.5 Waza Logone Floodplain, Cameroon

The Waza National Park lies in the Far North Province of Cameroon in a Sudano-Saharan grassland ecosystem. It was created as a hunting reserve in 1934 and then declared a national park in 1968 (Hakizumwami, 2000). The Waza National Park has an important animal diversity, especially avifauna with 379 species. There are at least 30 species of mammals, including elephant (*Loxodonta africana*), giraffe (*Giraffa camelopardalis*), lion (*Panthera leo*), spotted hyena (*Crocuta crocuta*), striped hyena (*Hyaena hyaena*), kob (*Kobus kob kob*), topi/korrigum (*Damaliscus korrigum*), roan antelope (*Hippotragus equinus*), red-fronted gazelle (*Gazella rufifrons*), warthog (*Phacochoerus aethiopicus*), Nigerian bohor reedbuck (*Redunca redunca nigeriensis*) and Grimm's duiker (*Sylvicapra grimmia*), in addition to smaller or less abundant species. The latter two species (reedbuck and Grimm's duiker) have become extremely rare and might join the list of species that have become locally extinct over the last few decades: the leopard (*Panthera pardus*), cheetah (*Acinonyx jubatus*), sing-sing waterbuck (*Kobus defassa defassa/Kobus ellipsiprymnus unctuosus/Kobus*

defassa unctuosus), bushbuck (*Tragelaphus scriptus scriptus*) and red flanked duiker (*Cephalophus rufilatus*) (Loth, 2004).

Impacts on Migratory Birds

It is believed that Lake Chad and its related floodplains are along key migratory routes, both of which have been adversely impacted as waterbird habitat by the SEMRY irrigation scheme and drought (Loth, 2004).

Impacts on Elephant and Livestock Populations, Waza National Park

Prior to 1947, there were no elephants in the 1,700 km² Waza National Park (de Iongh, Tchamba, Tamis, Van't Zelfde, Prins, de Haes, Bauer & Tiawoun, 1999; Loth, 2004). In 1962, elephant numbers had increased to a population of 150. Total dry season numbers in Waza were 465 in 1978, one year before the Maga Dam was constructed (de Iongh, Tchamba, Aarhaug & Verhage, 2004). By 1996, the elephant population numbers reached 1,100 and are believed to be at or beyond carrying capacity at about 1/km². The increased elephant population is a combination of natural reproduction plus in-migration from Nigeria and Chad (de Iongh *et al.*, 1999), some say to escape the Chadian war of the 1980s. By 2001, the number of elephants was estimated to be 1,140 (de Iongh, *et al.*, 2004). While the *Acacia seyal* woodlands of the Waza Park were important to feeding the elephants, they were not enough to support them year-round, pushing the elephants onto the floodplains to feed on perennial grasses such as *Echinochloa pyramidalis*, *Vetiveria nigritana*, *Oryza longistaminata* and *Hyparrhenia rufa* (Loth, 2004).

There are three elephant sub-populations (de Iongh, *et al.*, 1999; de Iongh, *et al.*, 2004):

- **Sub-Population 1, Waza Kalamaloué area.** Northern part of Waza in the wet season, migrating north to the Kalamaloué Park in the dry season (Jan-Feb) and returning at the end of the dry season (May-June);
- **Sub-Population 2** resides year-round in the Waza National Park; and
- **Sub-Population 3** tended to stay in the central and southern part of the park. Today, move south out of the park during the first rains (June/July), becoming problem animals in agricultural areas, and return in November-December.

The construction of the Maga Dam in 1979 resulted in decreased flooding and the succession from perennial (*Echinochloa pyramidalis* and *Oryza longistaminata*) to less palatable annual grasses (e.g., *Sorghum arundinaceum*). Just prior to the Maga Dam, the first 30 elephants from the third population were recorded moving south out of the park to the area of Mindif. With the Maga Dam in place, the number of elephants moving north decreased, while those moving south (Loth, 2004) increased at the onset of the rains. Two artificial waterholes in the *Acacia seyal* woodlands, along with decreased flooding and less palatable grasses, resulted in increased pressure on and degradation of the woodlands (de Iongh, *et al.*, 2004).

Between 1991 and 1997, the crop raiding elephants leaving Waza to the south during the rainy season increased from 50 to 330, significantly increasing the human-elephant conflict. Annual crop damage was valued at US\$ 206,000 compared to the US\$ 51,000 generated from elephants by tourism (Tchamba, 1998).

During the rainy season, only the cattle herds of the settled agricultural stock keepers, the Musgum, graze the floodplains on the left bank of the Logone River. During the dry season, 3,000 nomadic and semi-nomadic pastoralists such as the Fulbé (Fulani) and Shuwa Arabs from as far away as Nigeria enter the floodplain for six to eight months with over 200,000 cattle grazing on the rich perennial grasses. This is about 33% of the total cattle population of the Far North Province of Cameroon in which the left bank floodplains of the Logone and Waza are found. The nomadic Fulbé keep the larger more robust *bo'deiji* red long-horned breed of cattle, which is better adapted to the rigors of transhumance, while the agro-pastoral more settled Fulbé keep the smaller *gudaali* cattle. The sedentary Musgum keep an even smaller breed better adapted to the rainy season and flooding (Loth, 2004).

With regard to livestock, after the construction of the SEMRY rice irrigation scheme, the dry season herd was reduced to 80,000 tropical livestock units (TLU), a TLU being a 250 kg animal.¹⁷⁶ The area grazed was 1,200 km². It is estimated that the loss in cattle production was Euros 2,285 (US\$ 2,696) per km² or 11,750 TLU/km². The total loss was estimated at Euros 1,402,500/year (US\$ 1,654,950) to the pastoral economy resulting from decreased flooding and associated change from perennial dominated grasses to less nutritious annual grasses (Loth, 2004).

Section 7.10.7.5, Waza Logone Floodplain, Cameroon goes into some detail on the use of artificial flooding as a mitigative tool to overcome these problems.

¹⁷⁶ South Africa, the most advanced country in Sub-Saharan Africa in savanna research, uses a large-animal stock unit of 450 kg, about the size of a full-grown steer. Depending on the savanna type and thus energy available from the veld, the number of animals by species/large-animal stock unit is determined. This is used as an aid to the reserve, park or game ranch manager in determining the mix of wildlife and/or livestock on a property (Bothma, 1996).

7.8.9.6 Lower Kihansi Dam, Tanzania

With funding from the International Development Association (IDA), the World Bank's lending agency for the poorest countries, the Lower Kihansi Hydropower Project (LKHP) with a 25-meter dam and relatively small 26-ha reservoir on the Kihansi River in Tanzania's Rufiji Basin destroyed an 800-meter-high waterfall and brought development to a protected natural area, the Kihansi Gorge ecosystem, one of 25 "Global Biodiversity Hotspots" as designated by the IUCN. It is home to numerous endemic flora and fauna species (e.g., Kihansi spray toad, *Nectophrynoides asperginis*) that live in the spray of the gorge's 800-meter-high waterfall and are at risk of extinction because of this dam. The World Bank's environmental assessment only covered the most basic requirements, merely analyzing impacts on habitat inundated by the reservoir, but not downstream impacts on the gorge (IRN, 2001c).

7.8.10 Livestock and Wildlife Diseases

Reservoirs can provide habitat for livestock and wildlife disease vectors (this is also applicable to humans), and in the displacement of wildlife from the inundation zones have brought diseases such as sleeping sickness into livestock areas previously free of this disease.

7.8.10.1 Senegal River

The permanent presence of stagnant fresh water behind the Diama Dam favored the development of parasitic diseases affecting livestock, especially those caused by liver flukes with snail vectors as intermediate hosts. These ailments were rare in the delta prior to the Diama and are now very common. They have a major impact on livestock productivity. Herders have to expend major efforts to keep

livestock from entering the infested waters and to provide drinking water away from the river's edge. The epidemic of Rift Valley Fever, which occurred at the filling of the Diama Reservoir, probably a one off event, also caused great losses to livestock from abortions (Hamerlynck, *et al.*, 2000).

7.8.10.2 Kariba Reservoir, Zimbabwe, Zambezi River

Having nothing to do with Operation Noah (program to capture wildlife from Kariba inundation zone – see 7.8.9.3), the majority of wildlife on its own, including elephant and buffalo, moved out of the Kariba inundation zone as the reservoir filled into both the game reserves and into areas where the Ba-Tonga had been resettled. Both the people and wildlife were compressed into areas that were unfamiliar to them. Wildlife already existed in the game reserves, thus wildlife coming out of the inundation zone resulted in many areas exceeding carrying capacities for the vegetation to support them. For the first three years, until torpedo grass (*Panicum repens*) developed along the draw down zone of the Kariba Reservoir, hippos were found up to 27 km inland looking for grazing (Thomson, *pers. comm.*).

At the same time, major people and elephant/buffalo conflicts occurred as they invaded domestic crops. In the first year of resettlement, Ron Thomson, then a young Problem Animal Control (PAC) officer shot 600 PAC elephants and 100s of buffalo invading the farm plots of the Ba-Tonga, covering 12,950 km² (5,000 mi²) of control area with his team (Thomson, *pers. comm.*; Thomson, 2003).

Ron Thomson (*pers. comm.*) developed the Chizazira Game Reserve, blasting a 37 km (60 mi) road up the escarpment, which at one place climbed 2,000 feet in elevation over just 2.5 km (4 mi) of road. He observed that this PAC, along with the turmoil of 1,000s of displaced Ba-Tonga hewing out new lands and occupying

most springs and waterholes, pushed/compressed the elephant and buffalo even further from the Zambezi, up onto the 2,000 foot high mountain plateau of the Chizazira Game Reserve and into the Chete area. The entire miombo woodlands (*Brachysteigia spp.*) of the Chizazira Game Reserve were destroyed by elephants between 1964-1968, the same period in which elephant and buffalo moved southwards and eastwards out of the Zambezi Valley into the Rhodesian Highveld onto white-owned commercial farms and ranches. They carried with them sleeping sickness that was transferred to the livestock, something that had not existed before in these highland areas. Most tsetse fly along the Zambezi River was *Glossina morsitans*, which only carried *nagana* or cattle sleeping sickness. Human sleeping sickness here was very rare and carried by the *Glossina pallidipedes*, which lives only in deep shady areas (Thomson, *pers. comm.*; Thomson 1997; 2003).

A tsetse corridor was set up, running the length of the escarpment along the Zambezi, ranging from 13-155 km (5 to 60 miles) wide. Ron Thomson ran PAC in the Sebungwe Sector, inland from the upper part of the Kariba Dam, between the Sengwa River and Devil's Gorge where the Zambezi enters the impoundment. Thomson's job in the Sebungwe area was to shoot out all elephant and buffalo. Local Ba-Tonga called *magotshas*, a Tonga word for "butcher", were hired. They were equipped with British 303 Enfields and asked to shoot out all warthog, bushpig, kudu and bushbuck that were believed to be the intermediate host of the tsetse fly, which carried the sleeping sickness parasite. The *magotshas* shot everything: roan, sable, and zebra, wounding many elephant and buffalo in the process and taking lesser game that was not part of the mandate. Over the period of the tsetse fly eradication, officially 40,000 buffalo, elephant, kudu, bushbuck, warthog and bushpig were killed, mostly in the Sebugwe area of Binga and the Copper Queen Area. Ten's of thousands of other species were also taken. Unofficially, given the efficient work of the *magotshas* for non-target species, this

number could have easily doubled, making the 2,000 game species “saved by Operation Noah” relatively insignificant (Thomson, *pers comm.*; Thomson 1997). Thus, the Kariba Dam set off a series of events that disrupted the entire ecology and socio-economics of the area, from which the wildlife and people have never completely recovered.

7.9 SOCIO-ECONOMIC IMPACTS OF DAMS IN AFRICA

7.9.1 Dam Impacts on Displacement of People

The World Commission on Dams (WCD) (WCD, 2000) estimates that since about 1950, the beginning of the “big dam era”, globally large dams have forced 40-80 million people from their homes and lands, with impacts including extreme economic hardship, community disintegration and an increase in mental and physical health problems. Indigenous, tribal and peasant communities have suffered disproportionately (McCully, 2001; IRN, 2003). People living downstream of dams have suffered from water-borne diseases and the loss of natural resources, especially the floodplain ecosystem, on which their livelihoods depended (IRN, 2003). Estimates of people displaced by major dams in Africa are contained in Table 7.16.

Table 7.16: Major dams in Africa that have affected local communities

Name of Dam and Year(s) of Completion	River and Country	Impacts on People	Source
Akosombo Dam, 1965	Volta River, Ghana	80,000-84,000 displaced from 700 communities	IRN, 2000d; Hitchcock, 2003
Aswan Dam, 1902, 1912, 1934	Nile River, Egypt	Hundreds of Nubians and others displaced	Hitchcock, 2003
Aswan High Dam, 1970	Nile River, Egypt and Sudan	120,000 people displaced	Hitchcock, 2003
Cahora Bassa Dam, 1974	Zambezi River, Mozambique	1) 42,000 displaced in inundation zone 2) 350,000 people impacted downstream along floodplain	1) Isaacman & Sneddon, 2000 2) Beilfuss & dos Santos, 2001
Kainji Dam, 1968	Niger River, Nigeria	1) 44,000 displaced in inundation zone 2) 100s of thousands displaced from loss of floodplains downstream	1) McCully, 2001; Hitchcock, 2003 2) McCully, 2001
Kariba Dam, 1959	Zambezi River, Zambia and Zimbabwe	57,000 displaced total: 23,000 displaced – Zimbabwe side 34,000 displaced Zambia side	McCully, 2001; IRN, 2001a WCD, 1999; Thomson (<i>pers. comm.</i> ; 2003), IRN, 2001a
Kiambere Dam, 1988	Tana River, Kenya	7,000 displaced	McCully, 2001 & Hitchcock, 2003
Kihansi Dam, 2000	Kihansi River, Tanzania	22,000 people directly affected	Olsen, 2001
Lesotho Highlands Water Project, three dams; Katse Dam (1997), Muela Dam (1998) and Mohale Dam (2001) See: www.en.structure.de/structures for dates of start and completion of dams	Orange River, Maloti Mountains, Lesotho, diversion some say 40% (Tarico, 2002) to 67% of the Senqu/Orange River to another basin to supply the Greater Pretoria, Johannesburg area with water	1) Three dams dispossess 24,000-30,000 rural farmers of assets (including homes, fields and grazing lands) and deprive many of their livelihoods, totaling 4,645 ha pasture, 1,500 ha arable land from Phases 1A and 1B alone; 2) Katse Dam, directly displaces 2,000 people (300 households), 20,000 indirectly from loss of 925 ha arable land and 3,000 grazing land 3) Mohale Dam inundates 550 ha, resettlement of 400 families & b. impacting 7,400 people 4) Phase 1A (Katse and Muela Dams) adversely impacts 24,000 people, loss of 4,635 ha grazing land and 1,500 ha arable land, 312 homes relocated. Phase 1B (Mohale Dam), 7,400 people impacted, 300 homes relocated. 5) Downstream population at risk: 155,000 people (8,300 households in 338 villages) living along the rivers downstream of the LHWP structures and using the rivers for subsistence.	1) IRN, 2000a; IRN, 2001b IRN (2005) same figures but uses the term people instead of farmers 2) Bond, 2002 3a.. Bond, 2002 b. IRN, 2000a 4) Tarico, 2002 5) IUCN, 2002; Horta & Pottinger, 2005

Table 7.16 (Cont.): Major dams in Africa that have affected local communities

Name of Dam and Year (s) of Completion	River and Country	Impacts on People	Source
Maga Dam, 1979	Logone River, dam and 100 km embankment on left bank for irrigated rice	Adverse long-term impact on maximum 25,000 rural people using downstream floodplains for fishing, dry season grazing and agriculture	Njomaha, <i>pers comm.</i>
Maguga Dam, 2001	Nkomati River, Swaziland	66 households displaced	Hitchcock, 2003
Manantali Dam, 1988	Bafing River, Mali	1) 11,000 displaced behind dam, 2) Others say 10,000 displaced behind dam 3) 500-800,000 people displaced from loss of downstream flooding on Senegal River in Senegal & Mauritania	1) McCully, 2001; Hitchcock 2003 2) Diarra, Dolores, Yaouaga & Maiga, 1995 3) WCD, 2000 & Ryder, 2001
Masinga Dam, 1981	Tana River Kenya	6,000 people displaced	Bobotti, 2000
Roseires Dam, 1966	Blue Nile, Sudan	10,000 people displaced	Hitchcock, 2003
Ruzizi II Hydroplant	Rwanda/Zaire Border	15,000 people were displaced – more than 111 times the World Bank's original estimate.	McCully, 2001
Prepared by Principal Author			

“Typically the people to be displaced by a reservoir are underestimated, and often the numbers of people adversely impacted downstream from modification of floodplains are also underestimated or ignored altogether. Often the process of moving people from the area to be flooded is rushed and accompanied by violence and intimidation. The general impoverishment of communities, social disruption, trauma and health impacts are more severe on women than on men. Irrigation schemes tend to be badly managed, destroy soils, bankrupt small farmers, and turn lands that fed local people to production of export crops. Dams assist the powerful and wealthy to confiscate ‘Common Lands’

used for grazing, forestry, collection of herbal medicines, etc. of local communities – the politically weak - for irrigation. Often local people lose their lands to speculators. Marginalized ethnic minorities make up a disproportionately large percentage of those who lose their lands and livelihoods to dams. The remote mountain valley, forest or deserts are often their last refuge from cultural obliteration. This displacement often traumatizes entire communities, who have strong spiritual and ancestral ties to the lost land” (McCully, 2001).

Shocking as these case studies may seem, it is believed that forced relocation is more common than not across Sub-Saharan Africa as a result of the creation of both dam schemes, and parks and protected areas. Chapters 3 and 11 discuss a number of such relocations dating from colonial times including:

- 3.8.1 Land Compression Among the Last Hunters and Gatherers, Ju/'hoansi of Nyae Nyae, Eastern Bushmanland, Namibia.
- 3.8.2 Land Compression among the Bisa, Luangwa Valley.
- 3.8.3 Land Compression and British Colonial Policy, Tanzania (Tanganyika).
- 3.8.4 Land Compression and the Maasai of Kenya and Tanzania.
- 3.9.1 Eco-Genocide and the Elephant People.
- 3.9.2 Eco-Genocide and the San of the Central Kalahari Game Reserve (CKGR), Botswana.
- 3.9.3 Eco-Genocide and the Ik, the Mountain People.
- 3.11.1 Population, Kikuyu and the Mau Mau.
- 11.11.2 Donor Driven Conservation, Lake Mburo National Park (LMNP), Uganda.
- 11.11.5 Transfrontier Conservation Areas (TFCAs), Southern Africa.
- 11.11.6 Eco-Genocide in Southeastern Cameroon, the Forest People and the *Dobi Dobi*, More Parks and Protected Areas.

Forced relocation causes multidimensional stress (World Bank, 1982 *In: Colchester*, 1994). These stresses include (Colchester, 1994):

- Psychological stresses from loss of home and ancestral grounds, fear of the unknown future, vulnerability in being unable to protect one's home or surroundings.
- Physiological stresses appearing as health problems.
- Socio-cultural stresses such as those linked to the ancestors tied to the old home and land, loss of respect by society for traditional leaders that are made impotent by forced relocations.

"Societies that are removed from their lands not only lose the economic basis for their survival, but 'a major reduction in their cultural inventory due to a temporary or permanent loss of behavioral patterns, economic practices, institutions and symbols'" (Scudder & Colson, 1982 *In: Colchester*, 1994).

Compensation is usually inadequate (Scudder & Colson, 1982 *In: Colchester*, 1994).

"Thayer Scudder of the University of California has noted that 'forced resettlement is about the worst thing that you can do to a person short of killing him'" (Claxton, 1986 *In: Colchester*, 1994).

7.9.1.1 Senegal River

The Manantali's huge reservoir submerged almost 500 km² (50,000 ha) of fertile farmland and forests. The Manantali Reservoir caused the involuntary resettlement of 12,000 people (Ryder, 2001). GFCC (1980b) predicted that 13,000 people would be involuntarily resettled, while Diarra, Koenig, Yaouaga and Maiga (1995) estimated that the number would be 10,000 people. While the affected communities were allowed to select the resettlement sites themselves,

many families did not receive sufficient agricultural land and grazing grounds (Bosshard, 1999). The planners of the resettlement program for the Manantali failed to recognize that the sustainability of agricultural lands of the resettled communities would require a reserve of fallow land at least equal to that on which crops are grown since the productivity of these lands depended on slash and burn agriculture and ideally fallow periods of 20 years or more, although with increasing populations, fallow periods in West Africa were diminishing and/or even disappearing. The importance of common land to provide grazing for livestock was also ignored. The importance of women's kitchen gardens and wild foods gathered by women was also overlooked. Slashing the size of landholdings and people's access to the commons brings a risk of increasing hunger in the wake of an eviction – an ironic fact given that most dams are built with the rationale of increasing food production through irrigation (Diarra, *et al.*, 1995; McCully, 2001).

Once the Manantali Dam was built, however, the floodwaters needed for growing sorghum and keeping pastures fertile downstream in the valley all but disappeared. Once abundant fisheries collapsed and the valley became infested with waterborne diseases. According to the World Commission on Dams (WCD), between 500,000 and 800,000 people living downstream of the Manantali Dam lost all or part of their means of survival due to the virtual elimination of the river's annual floods (WCD, 2000; Ryder, 2001). Artificial flooding has been minimal. With the installation of hydropower stations in the Manantali, the chance of viable artificial floods becomes even more remote, though modeling by GFCC allowed for this over a 15-year period. Artificial floods could become a permanent process in the management of the Manantali Dam, though it is possible that a trade off would be income lost from a reduction in hydropower output (Section 7.10.7.1, Senegal River).

7.9.1.2 Gambia River

There did not appear to be any major village within the inundation zone of the Balingho Barrage. Major long-term adverse impacts were projected to result in the displacement and loss of livelihoods by as many as 43,099 women who depended on the 12,930 ha of tidal rice that would be permanently lost as a result of the Balingho Reservoir (University of Michigan, 1985c) (Table 7.17):

Table 7.17: Number of women who would lose their tidal rice fields as a result of the Balingho Barrage

Area	Ha	Number of Women
Tendaba To Balingho	1,930	6,433
Balingho To Kuntaur	11,000	36,666
Total	12,930	43,099

Source: University of Michigan (1985c), for USAID public domain.

The University of Michigan (1985a) study estimates that as many as 100,000 people lived within several kilometers of the floodplain that would be inundated by the Balingho Reservoir, estimating a minimum of 15,000 people who would have to be resettled. With the exception of the proposed Kekreti and Sambangalou Dams, displacement of people by the high dams was projected to be relatively minor, as these dams were for the most part located in undeveloped portions of the basin (Table 7.18):

Table 7.18: Agricultural lands and villages inundated by proposed high dams on the Gambia River

Proposed Reservoir/Altitude (m)	Agricultural Lands in Production in Inundation Zone (Ha)	Villages in Inundation Zone	Villages on Edge of Reservoir Jeopardized
Kekreti/65 (IGN)	1,705	20-28 (1)	16-20
Sambangalou/218 (IGN)	6,030 (Low Estimate 1,383)	9	12
Medina Kouta/204 (IGN)	1,968 (Low Estimate 392)	5	3
Kouya/300 (IGN)	283	7	8
Kouya/250 (IGN)	265	5	3

7.9.1.3 Zambezi River

Kariba Dam, Zambia

It is believed that the name Zambezi comes from *kasambabesi*, a name brought by the Portuguese from the coast, which means that only those who know can cross/swim. Most people called it the big river, the big one or the river that could never run dry – the only truth that will never end, a holy gift from God, which gave them food like a mother. The people living along the Zambezi River, which was to become the inundation zone of the Kariba Dam, referred to themselves as the “river people” or *bamulwizi*. They were hunters of elephant, cultivators on flood recession land and fishermen. They used the Tonga, Leya or Dombe speaking variations of the Tonga language and lacked strong traditions of centralized political authority, such as kings. It is claimed that these various names were used so that if the enemy sought the Tonga, they would sink their canoes and claim to be part of another tribe. They had many shrines along the

river, sacred pools, waterfalls and graves on islands. Many of the pools and waterfalls were used to bring rain through senior mediums or *mpande* (McGregor, 2003 *In:* Beinart & McGregor, 2003).

The actual resettlement of about 34,000 people on the Zambian side (WCD, 1999; IRN, 2001a; Thomson, *pers. comm.*) of the dam was begun at short notice once the decision to build was made (Table 7.16). The police in the then British colony of Northern Rhodesia (Zambia) shot dead eight villagers and wounded over 30 others in a confrontation during the poorly conceived and trauma ridden crash program to clear lands that were to become the Kariba Reservoir. Anthropologist, Elizabeth Colson, describes the 1958 evacuation to a resettlement area of some 57,000 Gwembe Tonga/Korekore people (on the Zambian and Zimbabwean sides of the dam) displaced by the Kariba: "They rode the swaying, open lorries for a hundred miles, over rough roads, in the blazing sun of the hottest period of the year...to reach an unknown land they dreaded...The misery of the trip was increased by nausea...They emerged exhausted sick to find themselves in what they regarded as a wilderness..." (From Scudder, 1993 *In:* McCully, 2001). During a two-month period shortly after resettlement, outbreaks of sleeping sickness, dysentery, measles and chicken pox killed more than 121 Kariba oustees, mostly children. Nearly a year later in 1959, an unexplained disease outbreak claimed the lives of 56 women and children.

On the Zambian side of the reservoir, anthropologists, Colson and Scudder, conducted a long-term study on resettlement showing that most of those moved on the northern bank of the Zambezi went into the Zambian hinterland, settling amongst host communities. Lusitu, to which 6,000 people moved on a second removal and Siameja have become dustbowls (WCD, 1999) due to the increased human population, which has exceeded the ability of the soils to support it. Tribal leaders (WCD, 1999) and mediums of ancestral spirits (McGregor, 2003 *In:*

Beinart & McGregor, 2003) lost much of their authority, as they were viewed with less respect due to having failed to prevent the forced removal. The results were land shortage, decimated livestock numbers, built up in the good years of the 1960s, and falling crop yields on mostly unsuitable land. This, along with Zambia's plunge into national bankruptcy and the official designation at the time as the country having the fourth highest percentage (80%) of rural poor, removed the possibility of the Tonga adapting their agricultural skills so that they could participate in the newer economic activities around the lake, or of escape to and absorption by the formal economy.

The major weakness of the resettlement program was that it failed to understand the intricate manner in which the Valley Tonga secured a living along the Zambezi. This led to poorly conceived resettlement and compensation that was inadequate. The Valley Tonga were moved mainly to "land" surveyed primarily as areas suited topographically for settlement, with little or nothing done to match soils, climate and their productive capability to the ecology of the Tongas' previous homes along the river. Fishing, though important in the beginning, could not serve all the families. This resulted in many settling far away from the lake where tsetse fly, poor soils, disappearing rainwater and unreliable harvests made it hard to cope. There is ample evidence to suggest that such marginal agricultural land is leading to soil and vegetation degradation and ultimately to desertification. "Today, the second generation after resettlement speak of a large out-migration of younger people to more hospitable areas with better facilities, land and greater access to markets" (WCD, 1999).

Kariba Dam, Zimbabwe

On the Zimbabwean side of the reservoir, the condition of the 23,000 resettled Tonga is similar to that of Zambia, mostly inland and the shore hard to reach.

Most of the shoreline went under public use, mainly as parks, partly in response to the emotions and with the help of private donations unleashed by Operation Noah, the highly publicized exercise that rescued animals trapped on islands as the waters rose (WCD, 1999; Thomson, *pers. comm.*; 1997) (see Section 7.8.10.2, Kariba Reservoir, Zimbabwe, Zambezi River).

The people were obliged to move into the interior away from the floodplains of the Zambezi that had provided them with their livelihood. There were 23 Ba-Tonga chiefs and their constituencies in the upper half of the lake: the Sengwa River dividing the lake into an upper and lower half (Thomson, *pers. comm.*). Those people who moved first were able to find pockets of black alluvial soil on which to grow their giant sorghum, but the vast majority of people ended up on ridgelines dominated by Kalahari sands. The giant sorghum grew poorly on the Kalahari sands, which were nutrient poor. The people were able to get about two years of production out of these sands and then were obliged to move on. A way of life was destroyed, namely permanent settlements along floodplains tied to the annual flood cycle of the Zambezi. In order to survive, the Ba-Tonga had to break up into smaller family units who relied on shifting slash and burn agricultural for survival. The people became dependent on food aid (Thomson, *pers. comm.*).

An attempt was made to provide them with a lower yielding faster growing sorghum more suited to the sandy soils. This sorghum was 0.9 meters (3 feet high) and matured in three months compared to six months for the traditional late maturing giant sorghum that grew 3.6-4.3 meters (12-14 feet) high (Thomson, *pers. comm.*).

Unfortunately, politics came into play. In 1965, the Unilateral Declaration of Independence (UDI) had been declared by the Smith government for Southern

Rhodesia, with its white government, that had not been independent from Britain but had practiced self-governance since 1923. A black independence movement was gaining strength. Black politicians told the Ba-Tonga that this new type of sorghum being given by the white man would make the men impotent. The women, who saw one of their major roles in life as childbearing and rearing, quickly put a halt to their men cultivating this sorghum. The Ba-Tonga have never recovered from their removal along the Zambezi, to this day remaining impoverished, dependent on the state and in a state of cultural deprivation, having lost their independence, pride and dignity (Thomson, *pers. comm.*; 1997).

The Zambezi River Authority plans to tax the water used for power generation to partly fund development programs and to attract donors. This move sets up a potential link between those removed from the lake 40 years ago to those who now benefit from the cheap generation of electricity throughout the region (WCD, 1999). Given the recent history of radical land reform beginning in 2000 and deteriorating economic conditions in Zimbabwe, it is unlikely that such goodwill will happen anytime soon. The poor and disenfranchised in all levels of society will continue to suffer in anonymity.

Cahora Bassa Dam, Mozambique

“There were far-reaching consequences for the displaced communities whose homelands and farms were flooded to create the massive reservoir. Yet it was not simply being evicted from their homes and ancestral lands that proved so devastating. The Zambezi peasants were herded into strategic hamlets with few basic amenities. These ‘*aldeamentos*’ were an integral part of Portugal’s broader counterinsurgency program designed to cut *Frente de Libertacão de Moçambique* (FRELIMO) off from its rural base of support. Although colonial authorities initially claimed that only 25,000 Africans would be displaced, by the end of 1973 the number had jumped to over 42,000. Conditions in the camps were rudimentary at best. A typical *aldeamento* contained

up to 1,500 residents. They lived in mud and wattle huts laid out in a grid enclosed by a barbed wire fence. The original planning documents called for each *aldeamento* to maintain a school, health clinic, water pumps, gristmills, warehouse for food reserves, social hall and football field. Except for a handful of model encampments, few of the ‘protected villages’ had all, or even most, of these amenities. Furthermore, the designated lands which the government had cleared were rocky and not very fertile and often far from the strategic hamlets. They stood in sharp contrast to the lands left behind. The arid conditions and absence of rain-fed lands dramatically reduced agricultural yields. So too did the colonial policies which limited each household to one small plot – typically less than a ha in size” (Isaacman & Sneddon, 2000).

In light of the restrictive government policies and the harsh environment, it is hardly surprising that the displaced communities experienced increased food shortages. There were also fewer opportunities to make up food deficits through hunting and fishing. In spite of government plans to protect the herds which roamed in the valley, large numbers of animals drowned when the Zambezi was impounded. Even in those areas where game survived, Portuguese military authorities prevented peasants from carrying rifles and severely restricted their movement (Isaacman & Sneddon, 2000).

Beilfuss, *et al.* (2002) provide similar descriptions of impacts. Fields being far from the strategic hamlets, it was not uncommon for peasants to depart before 6 a.m. in the morning and walk 5-7.8 km (2-3 miles) to get to their designated plots. To make matters worse, the lands that the government had cleared were rocky, hard to work and not very fertile (Beilfuss, *et al.*, 2002). Food insecurity and hunger were thus an integral part of the displacement process (Isaacman & Sneddon, 2000).

7.9.1.4 Waza Logone Floodplain, Cameroon

As with all floodplain ecosystems, the SEMRY rice scheme and especially its Maga Dam resulted in dramatic adverse long-term impacts on fish/fishermen,

agriculture/farmers, pasture production/pastoralists and their herds, migratory water birds and the wildlife of the 1,700 km² (170,000 ha) Waza National Park, especially elephants. From 1981 until the mid-1990s, this resulted in major environmental degradation and severe social upheaval, impacting up to 148,323 people in an area covering about 800,000 ha downstream of Lake Maga (Table 7.19):

Table 7.19: Economic losses from reduced annual flooding of the Waza-Logone Floodplain as a result of the SEMRY Scheme/Maga Dam

ECONOMIC SECTOR	TOTAL VALUE OF LOSSES FROM REDUCED FLOODING, (Euros/US\$)
Pasture Losses	1,402,500/1,654,950
Fisheries Losses	498,500/588,230
Agricultural Losses	340,000/401,200
Grass Losses (Thatch, Baskets)	304,900/359,782
Surface Water Supply Losses	19,800/23,364
NET COSTS/LOSSES	2,565,700/ 3,027,526

Source: Extracted from Loth (2004) with permission, International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU).

The total loss from the reduction in the annual inundation of floodplains as a result of the SEMRY scheme/Maga Dam of US\$ 3 million (Euros 2,565,700) to rural residents of the Waza Logone area (Loth, 2004) is 23% of the value of these resources prior to the implementation of this development scheme and its infrastructure.

7.9.1.5 Akosombo Dam/Volta Reservoir, Ghana

The majority of the 80,000 people who were relocated have never been provided with compensation, either in the form of money or in adequate land (IRN, 2000d).

7.9.1.6 Kiambere Dam, Tana River, Kenya

There was no relocation plan for the 7,000 people displaced by this World Bank funded dam. The displaced villagers went from poor to destitute. People were told that they had to leave with no alternatives. They lost their land, access to water and pasture for their cattle. Threatened by hunger, many found refuge in surrounding villages, vastly increasing pressures on the land. Reduced fallow periods for arable land and over-grazing of pastures created environmental stress. As a result, people in the communities that absorbed the displaced population also became poorer. A World Bank report states that families displaced by the Kiambere lost 82% of their money-equivalent income (which includes, for example, crops grown for household consumption) due to resettlement. The dam's electrical transmission lines pass over nearby villages, but not a single volt helps improve the lives of local people. "We are the cheap providers of electricity", says a farmer made landless by the dam (Horta, 1994).

7.9.1.7 Masinga Dam scheme, Tana River Kenya

"In 1981 after three years of construction, Masinga dam drowned an area of 115 km² (11,500 ha) of a river valley formerly a home to 6,000 people. These people became the displaced migrants to the surrounding rural areas and urban centers. They were monetarily compensated on basis of land lost and development as determined by official valuation and as required by law but with no systematic resettlement. That was the end of it. Public facilities like schools and health centers were reconstructed in the proximity of the old sites. Money given as compensation was not enough and the people became worse off. There has been no systematic monitoring of these displaced people and of their newfound settlements. A big lesson to manage future resettlements of displaced people was missed by this lack of monitoring" (Bobotti, 2000).

7.9.2 Dam Impacts Cultural and Spiritual Resources

The links of rural Africans to the lands of their ancestors, burial sites and sacred forests can never be replaced in resettlement zones, often causing psychological trauma and the breakdown in traditional society that may never be overcome by the displaced generation. These impacts are not much different to those created by the creation of parks and protected areas all over the continent that displace rural communities, where Westerners care more about wildlife than people.

7.9.2.1 Kariba Dam, Zimbabwe

“The Tonga people claim that Nyaminyami-Guardian of the River god, who is a direct descendant of their soothsayers and traditional healers, was angered by their removal from the dam inundation zone. This caused misfortunes such as the washing away of the foundation of the Kariba coffer dam during construction twice, in December 1955 and January 1958 as well as the death of 17 men trapped while working on the dam wall in February 1958” (Nhamo, 1999).

7.9.2.2 Cahora Bassa Dam, Mozambique

“The impoundment of the Zambezi River led to the flooding of a number of sacred shrines and burial sites. Many peasants believe that because they are no longer able to propitiate the dead they have alienated powerful Tawara and Tonga royal ancestor spirits (*Mhondoro*). Because they have angered the royal ancestors' spirits they no longer receive divine protection and therefore have suffered from divinely inspired droughts, famines, and diseases. They also could not rely on the protection from the *Mhondoro* during the brutal civil war in which thousands of peasants were killed or maimed. The oral data underscores the deep sense of cultural obliteration and vulnerability experienced by the dislocated communities” (Beilfuss, 2001).

7.9.3 Dam Impacts on Ethnic and Other Conflicts

The loss of dry season floodplain habitat by pastoralists from both flooding and irrigation can result in ethnic conflicts. Dams have also become political tools of ideological and liberation conflicts.

7.9.3.1 Senegal River

The Manantali Dam has not just affected local patterns of agriculture, but has led to violent conflict at a regional level as well. The crisis was caused by the dam itself, which had upset intricate water-sharing arrangements between Senegalese farmers, cattle herders and Moorish¹⁷⁷ traders (Sevunts, 2001). New landownership laws in Senegal and Mauritania, strongly promoted by the World Bank, IMF and French Fund for Assistance & Cooperation (FAC), enabled wealthy nationals and foreign companies to privatize land in the Senegal River Valley, on which traditional peasant owners had no formal rights (McCully, 2001).

When the dam project opened with new prospects of commercial agriculture, land legislation in Mauritania was rewritten in order to abrogate the land rights of the peasants who had lived along the Mauritanian riverbank for generations. The Arab-speaking elite Moors expropriated huge land areas (McCully, 2001). The Moors, who before had had little interest in agriculture, expropriated land in anticipation of making large profits from the development of medium and large-scale irrigation schemes with backing by the security forces. Thousands of black Mauritanian nationals as “foreigners” were kicked off their land (Colchester, 2000). This increased pressure on flood land outside of commercial control, and

¹⁷⁷ There are both white and black Moors

heightened ethnic tensions on the north bank of the Senegal River, where black farmers are perceived as Senegalese by Mauritanian herders (McCully, 2001).

Ethnic conflicts in the region preceded the arrival of the newcomers in the Senegal River Valley. Because these violent outbreaks, also referred to as *les événements*, coincided with the completion of the dams, many believe that there exists a direct link between the two events (Bossard, 1999a; Adams, 1999; Horowitz, *et al.*, 1990 *In:* Kloff & Pieterse, 2002). In 1989, just after completion of the two dams, the killing of sedentary Senegalese farmers by nomadic Mauritanian herdsmen in the river valley triggered the ethnic conflicts. In Senegal's capital, Dakar, 100 to 150 Moorish shopkeepers were killed and 10,000s of Mauritians fled from Senegal to Mauritania. Also in Mauritania's capital, Nouakchott, 100s of black people were killed. About 70,000 flood-recession farmers fled from the Mauritanian side of the river to Senegal. The military of the two countries engaged in armed skirmishes and nearly went to war over the conflict (Homer-Dixon, 1994; Bossard, 1999a; Ryder, 2001; Horowitz, *et al.*, 1990 *In:* Kloff & Pieterse, 2002).

The restructuring of the river most probably triggered the conflict. During the pre-dam period, the sequential use of the same lands by flood-recession farmers and herdsmen contributed to social cohesion and peace. This harmony was disrupted by rapidly developing irrigation schemes. Vast seasonal grazing lands in the river valley diminished and previously amicable relationships between ethnically distinct herdsmen and farmers deteriorated. Dikes were now surrounding the agricultural lands, blocking access by herdsmen to freshly harvested land. The killings that triggered *les événements* were probably the direct result of deteriorating relationships between farmers and herdsmen because of dam building and new irrigated perimeters (LeBillion, 2000 *In:* Celliers & Dietrich,

2000; Kloff & Pieterse, 2002).¹⁷⁸ The incident escalated and also spread to other regions after an accumulation of ethnic tensions that go further back in time (e.g., slavery) and that are not directly linked to the erection of the dams. A “burning belt” exists at the transition zone where nomadic desert life meets sedentary Sahelian life, a line of conflicts and wars from Mauritania to Sudan. These conflicts are quite similar to what happened or still could happen in the south of Mauritania (Kloff & Pieterse, 2002) (see Chapter 5, Section 5.11, CONFLICT LINKED TO OVERPOPULATION AND DESERTIFICATION – SCARCE RESOURCES). Much of this is believed to be due to factors such as decreasing fallow forcing farmers into traditional herding areas, loss of dry season floodplains from so-called “development” or “conservation”, creation of “open access” resources by central governments obliterating traditional management systems, dry season fodder on farms being used for fuel as forests disappear under an increasing wave of humanity, and old tensions from slave/master relationships. Slavery still exists in Mauritania, with white Moors having black slaves and in Senegal and Guinea-Conakry where blacks have black slaves and/or there are slave classes.

7.9.3.2 Cahora Bassa Dam, Mozambique

The Cahora Bassa Dam is linked to the struggles between *Frente de Libertacão de Moçambique* (FRELIMO) and the colonial state and later between the Mozambican government and South African supported *Resistëncia National Moçambicana* (RENAMO) rebels. The dam was initially conceived as a way for the colonial state to retain power over its territory as evidenced by the selective character of pre-dam investigations and subordination of social and environmental considerations by colonial planners intent on transforming the river regardless of

¹⁷⁸Note: Loss of traditional dry season grazing areas from reduced flooding forced pastoralists into farming areas and farmers displaced due to expropriation of their land would have been pushed into traditional grazing areas on the floodplains

the cost. Portuguese officials believed that the project would blunt FRELIMO guerrilla advances south of the strategic Zambezi River. They theorized that the 500 km (193 miles) long reservoir would impede access by FRELIMO forces to the heart of Mozambique from bases in Zambia and Malawi. They predicted that economic development stimulated by the dam would increase the size of the white settler community to 80,000, providing the first line of defense against the guerrillas. However, there was little evidence of settler interest in this malaria-infested region (Isaacman & Sneddon, 2000).

“The nationalist forces contended that Cahora Bassa was an integral part of a military and economic alliance between Portugal and South Africa designed to provide cheap energy to South Africa and perpetuate white rule in the region. For almost 7 years, FRELIMO waged an unsuccessful guerrilla campaign to block construction of Cahora Bassa which was completed in 1974” (Isaacman & Sneddon, 2000).

Independence intensified the conflict over Cahora Bassa between the new government and the Apartheid regime of South Africa. Concerned about FRELIMO’s historic ties to the African National Congress (ANC) and its non-racial socialist agenda, South African security forces began a military and economic campaign to destabilize the Mozambican government and destroy the country’s infrastructure with Cahora Bassa high on its list. Within six months of Mozambique’s independence in 1975 and take-over by FRELIMO, South African security forces working with Rhodesian counterparts created, trained and armed the *Resistência Nacional Moçambicana* (RENAMO) insurgents. Between 1976 and 1979, Mozambique suffered from more than 350 RENAMO and Rhodesian attacks. Although the dam itself was left unscathed, power lines were sabotaged on a regular basis for more than a decade (Isaacman & Sneddon, 2000).

The building of power stations to provide energy from the dam to the provincial capital Tete and nearby coal mines, plans to use the dam's water to irrigate more than 210,000 ha of choice farmlands in the valley, an agreement with India to set up an aluminum plant and plans to develop the commercial fishing, tourism and shipping industry on the reservoir never got underway due to South Africa's destabilization campaign. This ensured Pretoria's hegemony over the region in order to defend the political and economic interests of the Apartheid state and to insulate the African National Congress from linkages to sympathetic regional regimes (Isaacman & Sneddon, 2000).

The Mozambican government lacked the capacity to protect the 4,000 pylons cutting across 900 kilometers of remote country. As early as 1981, RENAMO dynamited pylons, which reduced electricity exports by 50%. It took six months to repair the lines. The cost of repairing the power lines of US\$ 500 million was almost three times the total value of Mozambican exports. The dam remained a white elephant, benefiting neither the national economy nor local economies of a struggling Mozambique (Isaacman & Sneddon, 2000).

Among the most vulnerable communities were the peasants displaced by the dam into strategic hamlets during the colonial period. Since their original homes were underwater, most had little alternative but to remain where they were. They were easy prey for RENAMO forces, which would go into homes and steal, order the people back into their homes and then set them on fire. This destroyed the social fabric of society among riverine communities, while paralyzing electricity production so that Mozambique derived no economic benefits whatsoever from the dam. From 1982 to 1997, Cahora Bassa's five massive generators stood idle (Isaacman & Sneddon, 2000).

7.9.4 Dam Impacts on Rural Electrification

The regrettable fact is that communities resettled by dams in Africa are rarely provided with electrical power by the dam they helped to create. This hydropower is destined for the wealthy in the big cities, irrigation and industry. The rural poor remain poor, or in many cases the displaced become poorer after this “development” takes place.

7.9.4.1 Senegal River

The inhabitants of 30 villages who were resettled downstream were allocated infertile and insufficient land to farm. They have no health centers and, although they are just a few kilometers from a dam that would be providing power for cities as far away as Nouakchott and Dakar, no electricity (Baxter, 2001).

7.9.4.2 Kariba Dam, Zimbabwe

An on-going irony that still frustrates many of those resettled is that electricity has formed no part of that program. This is explained by the cost of “stepping down” the supply to localities and the mainly widely dispersed nature of that resettlement. This is typical of most dam schemes in Africa and the developing world in general; the lives of the rural poor displaced by the dams are forever damaged, and links to electrical power destined for industry and urban centers escape them (WCD, 1999). By 1980, only 14% of Zimbabwe’s households, virtually none in rural areas, had access to electricity. A rural electrification program in the 1990s raised this to only 20% of the households. By then, the Kariba debt had been paid off to the World Bank. In addition, the majority of the people could not afford market-related electrical rates, which led the World Bank

and UNDP to push for a reforestation program.¹⁷⁹ Additional loans from the Bank to refurbish the Kariba and pressures to increase user fees, cutting off access to the majority of Zimbabweans, resulted in only 21% of Zimbabwe's population having electricity by 1996 (Bond & Manyanya, 2003).

7.9.4.3 Akosombo Dam/Volta Reservoir, Ghana

After nearly 40 years since the construction of the Akosombo Dam, almost all of the 52 resettlement communities that were created following the construction of the dam have yet to be supplied with electricity (Anane, 2001).

7.9.5 Dam Impacts on Downstream Irrigation

It is rare that irrigation schemes have reached the projected areas to be brought under production. Meanwhile, modification of the hydrological regimes has destroyed the traditional production systems that have fed man for centuries.

7.9.5.1 Senegal River

On the Senegal River, *the Société d'Aménagement et d'Exploitation des terres du Delta du Fleuve Sénégal* (SAED) was the state parastatal tasked with oversight of irrigation development in the Senegalese portion of the river. It had begun working with small-scale irrigation further north on *périmètres irrigués villageois'-PIV* (villager irrigated perimeters), which developed rapidly in the valley on the Senegalese side, increasing from 20 ha of irrigated land in 1974 to 13,000 ha in 1986 (Adams, 2000a) and 18,000 ha by 1988 at 700 sites (Boone,

¹⁷⁹ The history of forest plantations for firewood in Sub-Saharan Africa has not been positive (see Chapter 9, Section 9.8.9.3, Community-based natural forest management, *Gestion des Terroirs*, Burkina Faso).

2003). Yields were good. Had it not been for OMVS and the Senegalese government's plans of dam building and large-scale hydro-agricultural schemes, there might have been a small chance of PIV's success influencing river development plans, which might have enabled it better to weather the storms of the 1980s (Adams, 2000a). Boone (2003) explains that the PIV system was begun by peasant farmers in the Upper Valley, who used motor pumps to draw water from the river to land above the normal floodplain that was not controlled by the Soninké elite even though much of the floodplain was uncultivated. In 1976, the Senegalese government intervened to centralize control through SAED to develop rice-producing PIVs along the Upper and Middle River. The average household plot size in a PIV was 0.25 ha. In a power sharing relationship with central government, control over tenure was conceded to the ruling Fouta (Toucouleur) oligarchy in the Middle Valley and Soninké oligarchy in the Upper Valley. This was despite the fact that the 1964 National Domain Law over land tenure abolished "traditional landholders" to free peasant farmers from bondage by the rural elite. The rural elite took over control of the PIV's who benefited from credit and subsidized agricultural inputs. At the same time, they retained their traditional control over the floodplains. SAED was to deduct the cost of inputs after buying the rice harvest from farmers. However, most farmers consumed the produce themselves and/or sold the rice on local informal markets, SAED commercializing not more than 35% of the rice produced in the Upper and Middle Valley. Costs on the small plots within the PIV proved to be too high to make this commercially viable (Boone, 2003). The peasant families who had lived in the Senegal Valley for many decades could often not afford the inputs needed for irrigation farming (Bosshard, 1999). Between 1985 and 1990, SAED withdrew producer subsidies and PIVs were abandoned, leaving farmers even more vulnerable due to the disruption of flood recession agriculture by the Manantali Dam. This forced many farm families in the Middle Valley to depend on rotational migration to Dakar (living on remittances), commercial activities

and wage employment in the delta (Boone, 2003). Koopman (2004) goes into some length in discussing the loss of subsidies and supports to small scale irrigation farmers in the SRC beginning in 1985/6 with structural adjustment policies (SAPs) imposed on Senegal by the IMF.

SAED created an artificial peasantry in the delta that was socially heterogeneous. Between 1980 and 1987, as the Senegalese government gradually pulled back from managing large-scale rice estates in the delta, there was a speculative land rush by Dakar *fonctionnaires* (government workers), Mouride marabouts, merchants and SAED technicians eager to make a profit before salinization set in. From 1981-83, 40% of the requests for land grants around *Lac de Guiers* were made by persons residing outside of the rural council areas along with local “peasant aristocracy” such as village chiefs and presidents of cooperatives. Gradually, peasant associations made similar requests but appeared to have little political clout (Boone, 2003). In the Lower Valley (Delta), peasant farmers were sometimes forced into sharecropping arrangements with prosperous outsiders. With irrigation, the traditional sorghum crop was replaced by rice. Even for the richer farmers, however, irrigation proved to be more cumbersome and less productive than the project planners had expected. Since there has been no electric power (until 2001), expensive diesel for running the pumps (as well as seeds and pesticides) had to be purchased.

Due to organizational (little autonomy to farmers) technical (high saline groundwater tables) and operational problems such as farmers’ refusal to reimburse debts, delays in the delivery of inputs, poor maintenance of infrastructure problems, and high production costs, irrigation has never taken off as planned (Boone, 2003). Once Senegal, where most of the irrigated land is situated, underwent structural adjustment (SAP) beginning in 1985/6, the government could no longer afford to subsidize inputs or credits. The harvest

from the Senegal River Valley could not compete with rice imported at world market prices (Bosshard, 1999). At a cost of US\$ 25,000-40,000/ha, the construction of large-scale irrigation networks fed by the Manantali Reservoir proved to be more expensive than originally planned. Instead of 375,000 ha (255,000 ha – GFCC, 1980b), only about 100,000 ha have been brought under irrigation so far, with only about 2,000 ha/year added (Bosshard, 1999; World Bank, 2001; WEC, 2003). According to SAED's own statistics, the total area laid out for irrigation on the Senegalese bank of the river was 71,751 ha in 1995 and the area actually farmed that year, in all seasons, was 29,792 ha (Adams, 2000a). The World Bank (2001) estimates of the 100,000 ha in irrigation about 60,000 ha are farmed mostly in rice during the rainy season and 20,000 ha during the dry season. Koopman (2004) estimates that Senegal still imports 500-600,000 tons of rice a year, spending about 20% of its export earnings.

This problem was supported by similar conclusions about irrigation on the Senegal River examined as a means of assessing potential viability just south on the Gambia River. In the early 1980s, the rapid deterioration of infrastructure and irrigation equipment on the Senegal River resulted in a rate of abandonment about equal to the rate of expansion. Likewise, the cropping intensity for those perimeters in irrigation in 1983 was estimated at 122%, well below the projected rate of double cropping (200%), (University of Michigan, 1985a).

The inability of the Senegal Valley to compete with rice imported at world market prices was known by the GFCC consultant Walter Firestone, the agronomist on the Senegal River Basin (SRB) Environmental Assessment. However, his concerns were ignored. The environmental assessment was fairly accurate in its predictions on the loss of dry season forage, recession agriculture, and fish production, but it refused to take into account Firestone's concerns that 1) pumped irrigated rice was not economically viable and 2) rice could be imported

cheaper from Asia than grown by pumped irrigation in the Senegal River Valley, especially the delta (Firestone, *pers. comm.*¹⁸⁰; Rosenblum & Williamson, 1990). Unfortunately, it appears that GFCC was willing to sacrifice the people of the Senegal River Valley for what they hoped would be their next contract.

7.9.5.2 Gambia River

From the standpoint of pure rice production, a high dam with irrigation upstream of Kuntaur and improved swamp culture between Balingho and Kuntaur appeared to be the most advantageous development scenario (see Figure 7.3: Dams in the Gambia River Basin). This would require a regulated flow from a high dam of 3 m³/second maximum at Gouloumbou to keep the “1 part per thousand (ppt.)” salinity regime downstream of Kuntaur (km 250) once it reaches this point during the dry season, necessary to assure maximum rice production in the Lower Freshwater River Zone (Risley, 1986 *In:* Samba & DeGeorges, 1987a; 1987b & DeGeorges, 1987c). This was based on the Streamflow Synthesis and Reservoir Regulation (SSARR) model developed by the U.S. Army Corps of Engineers in the 1950s for the Columbia River Basin and applied to the Gambia River. Within this model, there was a watershed basin model, a flow routing model, a backwater model for estuary simulation and a reservoir operation model.

For single cropping, it was projected that a “salt free” zone less than 1 ppt. is needed from June/August until November and for double cropping until April/May (Euroconsult, 1986 *In:* Harding & DeGeorges, 1987). This would permit double cropped pumped irrigation of about 40,000 ha (Table 7.20) in the estuarine basin of The Gambia where approximately 80% of all irrigation, both tidal and pumped, would take place.

¹⁸⁰ Walter Firestone, Utah, USA, Agronomist, Senegal River Basin Environmental Assessment, funded by USAID and run by Gannett Fleming Corddry and Carpenter

Using the 2,300 calories/day/person (GFCC, 1980b) as the minimum intake for a healthy adult, the high dam options would meet the needs of 1,786,778 people/year (Table 7.20).¹⁸¹

Table 7.20: Projected rice yields in the estuary and Lower Freshwater River Zone with high dam options only (no Balingho Barrage), Gambia River

Location	Ha (1)	Yield (Metric Tons Rice) (2)	Protein Gain From Rice (gm) (3)	Carbohydrate Gain From Rice (Calories) (4)
Pumped Irrigation, Upstream Kuntaur	40,000	360,000	238×10^8	12.6×10^{11}
Improved Tidal Rice, Balingho-Kuntaur	49,000	56,350	37×10^8	2.0×10^{11}
Tidal Rice Upstream of Kuntaur	9,089	14,542	9.6×10^8	0.5×10^{11}
Tidal Rice Tendaba To Balingho (Mangrove Soils)	1,930 (5)	1,351	0.9×10^8	0.05×10^{11}
Total		432,243	286×10^8	15×10^{11}

Prepared by principal author

Irrigation potential in Senegal Oriental between the Gambian border and the Niokolo Koba Park was estimated at 4,900 ha. A high dam on the Gambia River in Guinea-Conakry would permit the additional irrigation in Senegal of 6,000 ha

¹⁸¹ See Chapter 5, Section 5.3.3, Food Security in Africa for latest figures used as standards below which a population is considered undernourished.

upstream of Kedougou above Niokolo Koba – thus an additional 10,999 ha of irrigated land (Samba & DeGeorges, 1987a).

From an agricultural standpoint, the proposed Kouya Dam received a slightly favorable rating because it permitted the irrigation of an additional 3,000 ha downstream in Guinea-Conakry. The Sambangalou and Medina Kouta Dam options would permanently inundate a portion or all of this area. However, the Sambangalou and Medina Kouta Dams on the Gambia River would retain much more water for hydropower¹⁸², irrigation, creation of artificial floods and estuarine maintenance. An additional dam, the Kogou Foulbe Dam on the Koulountou River within the Gambia River Basin, would allow the irrigation of another 12,000 ha for vegetables, maize, sorghum and rice (University of Michigan, 1985a).

Mini-Barrages in the mid-section and headwaters of the Gambia River Basin (Senegal and Guinea-Conakry) would permit incremental development over time. A minimum of 12,000 ha was identified in Guinea and in Senegal about 6,000 ha upstream of Kedougou and 4,900 ha of good to very good land was identified between the Gambian frontier and the Niokolo Koba Park that could be served by irrigation from mini-barrages.

7.9.5.3 Waza Logone Floodplain, Cameroon

Irrigated rice dates back to the post-WWII creation of the rural development company *Secteur Expérimental de Modernization du Nord* (SEMNORD), established to disseminate technologies on food crops. By 1954, the *Secteur Expérimental de Modernisation de Riziculture de Yagoua* (SEMRY) was

¹⁸² Average annual production in GWh/Year & Potential Power (Mw): Sambangalou/911-1,086 & 104-124, Kouya/334 & 30, Medina Kouta/137-269 & 14.4-67 and Kekreti/157 & 20 (Samba & DeGeorges, 1987a).

established and by 1965 was supervising 10,000 farmers cultivating 6,500 ha that produced 10,000 tons/year of paddy rice. It was determined that with an embankment to stop flooding into the rice fields, fertilizers, improved varieties and controlled irrigation by pumping, production could increase yields to 16,000 tons/yr; 40% of the national consumption. To avoid the high cost of production, the Maga Dam would be needed to store water and allow for gravity fed irrigation. Recommendations to SEMRY by the French consulting company SOGREAH to release water between September and November from the Vrick sluice gate to allow for artificial flooding were ignored. Once the dam was in place, there was no monitoring downstream on the ecological, hydrological or socio-economic impacts of the Maga Dam and the SEMRY scheme. A second phase, SEMRY II, built a 21 km embankment without appropriate studies, which would have shown that it was not needed to protect the rice perimeters, but would have dramatic adverse long-term impacts on the floodplain ecosystem, the Waza Park and the people living from the floodplain resources. There was no involvement of local communities in the planning process and when the communities requested that the Petit Guruma Channel be left open to allow for flooding, their advice was ignored (Loth, 2004).

“SEMRY I & II have been in financial difficulties since 1987. After the poor results of the 1st restructuration plan in 1991-1994, the Cameroon government launched a second restructuration plan as from the year 2000. This second plan will last till 2006 and SEMRY will benefit some 7 billions CFA (about Euro 10.8 million/US\$ 13.4 million) to renew its equipment (tractors, bulldozers, etc.), to cure irrigation canals, to reorganize and train farmers and to set up a functional credit system for input purchase and rice marketing. After 2006, the corporation is expected to operate on its own without any additional government assistance. If results are still poor, the company will be then closed.

For the moment, SEMRY I and II plough annually 50 to 60% of the total land available (11,600 ha). The 2 units have some 21,000 rice farmers. If you consider that each farmer takes care of seven

people (on average), you have about 150,000 people who depend on SEMRY rice production. Adding other people who are in charge of fertilizers trade, rice processing, wholesaling and retailing, you may end up with 200,000 people living on SEMRY rice production and marketing.

Total costs of production (for 0.5 ha) vary from 217,000 CFA (Euro 332/US\$ 415) to 270,000 CFA (Euro 412/US\$ 515) depending on the types and quantities of inputs used. Yields (per ha) vary from 25 to 40 bags of paddy rice. At production sites (Yagoua and Maga), clean rice costs about 250 to 300 CFA per kg (Euro 0.38-0.46/US\$ 0.48-0.58/kg), which is equivalent to the wholesale price of imported rice in Douala after customs clearance at the seaport. Due to high transportation cost from Maga-Yagoua to the major urban and consumption centers (Douala and Yaoundé which are 2,000 km away), the SEMRY rice becomes more expensive than the imported rice from Asia. Consequently, SEMRY rice is mostly sold in northern Cameroon, in Nigeria and in Tchad, which are close to the production sites" (Njomaha, *pers. comm.*).

According to Loth (2004), this amounted to 27-30 bags/ha averaging 2.3 tons of rice/ha, which, based on the above prices, would be valued at CFA 575,000-690,000/ha (Euro 879-1,055/US\$ 1,099-1,319/ha).

7.9.5.4 Nile River, Aswan High Dam

All but a small proportion of Egypt's agriculture is now dependent on regulation of the Nile River by the Aswan High Dam, completed in 1971. Government sources claimed in 1993 that 690,000 ha had been reclaimed from the desert since the high dam was built (McCully, 2001). FAO (1997) shows 852,000 ha reclaimed, but 210,000 ha of this reclaimed land going uncropped or a net of 624,000 ha in irrigation by 1992. FAO statistics show that actual irrigated land in Egypt in 1989 was 2.6 million ha, virtually unchanged from the area irrigated in 1961 when construction began on the dam (McCully, 2001). An estimated 100,000 ha of fertile topsoil has been mined to make bricks since the loss of the annual flood deposits of silt in the pre-High Aswan era, resulting in brick factories

buying up farmland to quarry. Urbanization has also resulted in more than 125,000 ha of formerly irrigated land being lost. Water logging and salinization from perennial irrigation are also a major issue (McCully, 2001).

“It should be noted that each time new land is reclaimed it is of a lower quality than the already cultivated land. The ‘best’ soils in Egypt cover an area of only about 1 million ha, while the ‘best’ plus ‘suitable’ soils cover an area of about 3.6 million ha. Adding the still more marginal land, the maximum area for agriculture could be 4.8 million ha. The remaining soils are unsuitable for agriculture. Taking an average water requirement of 13,000 m³/ha/year in the Nile Valley and Delta, about 4,420,000 ha could be irrigated using the 57.4 km³/year of Nile water” (FAO, 1997).

FAOSTAT (2004) indicates that 3,400,000 ha were in irrigation by 2002, Egypt apparently rapidly approaching its maximum potential.

However, the sum of the irrigation potential of all countries in the Nile Basin (Egypt, Ethiopia, Sudan, Uganda, Rwanda, Burundi, Tanzania, Eritrea, Kenya and the DRC)

“leads to a water deficit of over 26 km³/year, without considering possibilities of reusing water as indicated by Egypt and Sudan in their water balance, but after deducting the water ‘losses’ in the Sudd region” (FAO, 1997).

“This deficit corresponds to an area of almost 2.2 million ha for all countries, considering an average water requirement in the region of 12,000 m³/ha per year. This leads to an irrigation potential for the basin as a whole of 8 million ha instead of the nearly 10.2 million ha projected. However, even these 8 million ha are still a very optimistic estimate and should be considered as a maximum value, requiring very important storage works and optimum water use” (FAO, 1997).

Some argue that a potential water war looms in the future over its allocation for irrigation and the construction of dams for water storage in the Nile Basin (Klare,

2001). Turton (2001) describes similar hydropolitics and water security issues in Southern Africa (see Chapter 13, Section 13.11 AFRICA'S POTENTIAL WATER WARS).

7.9.5.5 Sennar and Roseires Dams, Sudan

Britain dammed the Nile at Sennar in the Sudan in 1925 for the Gezira Scheme, one of the world's largest cotton plantations. Almost 66% of modern large-scale irrigation in Sub-Saharan Africa is in Sudan. The Gezira scheme covers 840,000 ha, half the irrigated area in Sudan. Watered from the Sennar and Roseires Dams on the Blue Nile, it was first developed by the British in the 1920s, replacing traditional sorghum and nomadic herding with cotton. Cotton for export is the major crop grown even today. Even so, 33% of the children in Sudan suffer from chronic malnutrition (McCully, 2001).

"Irrigation potential in Sudan has been estimated at over 4.8 million ha, but this figure does not take into consideration the available water resources. There are plans to increase irrigation to about 2.8 million ha by the year 2000, almost all to be irrigated by Nile water" (FAO 1997).

Water management is a problem, as on the old established cotton schemes of Gezira-Managil where available water is 12% below crop requirements at crucial points in the growth cycle, while as much as 30% of the water delivered is not used by crops (FAO, 1997).

7.9.5.6 Bakolori Dam, Nigeria

Located on the Sokoto River, a tributary of the Niger River, the Bakolori Dam reduced the area of downstream rice production by 7,000 ha, and dry season crops by 5,000 ha. The dam altered the timing and extent of the flood. Dry season

water tables fell, requiring deeper wells and increased expenditures in time and money on watering crops. A 1980s survey showed that 75% of the dry season irrigators had given up farming, only the richer farmers surviving. Projected yields of groundnuts (peanuts) were only 69% of those predicted by the agricultural economists, rice 56% of the projected yield and cotton 17%. In 1971, the Nigerian Department of Agriculture estimated that Nigeria would have 320,000 ha under large-scale irrigation by 1982. By the end of 1980, less than 31,000 ha were under modern irrigation (McCully, 2001).

7.9.5.7 Kiambere Dam, Tana River, Kenya

By 1994, the project was reminiscent of a ghost town with abandoned water towers, overgrown irrigation canals and 20,000 desperate and hungry settlers. Downstream from the Kiambere Dam, the Bura irrigation project is an unmitigated disaster: the result of remarkably poor planning and institutionalized conflicts of interest. The Bura irrigation project, which the World Bank funded in the 1980s, was to irrigate about 14,170 ha (35,000 acres) to grow cotton and maize at an estimated cost of US\$ 98 million. The area actually irrigated peaked at just about 2,249 ha (6,000 acres) at a cost of US\$ 108 million, while social and environmental project components were canceled. In a country where per capita income is only about US\$ 350/year, the project spent an incredible US\$ 55,000 for every settler on the project site. Yet today, these settlers and their families suffer abject poverty, drought and famine. The project has also led to the destruction of evergreen floodplain forests, which were rich in plant and animal species (Horta, 1994; Horta, 1994 *In:* McCully, 2001). Only people with nowhere left to go remain on the project site. They are a community of about 20,000 former herders who sold their cattle, and farmers who left more fertile areas of the country for the promise of irrigated agricultural land. Much of the money for the Bura project was borrowed from the World Bank on non-concessional terms and

will have to be repaid at high interest rates. The Bura project will be a burden to the Kenyan economy for years to come and the debt will have to be repaid in hard currency, adding pressure to increase exports to generate foreign exchange. More of the country's resources will be diverted to activities such as flower production for European markets, while several million Kenyans risk becoming victims of drought and famine (Horta, 1994; Horta, 1994 *In: McCully, 2001*).

7.9.6 Impacts on Soil Linked to Agriculture

As discussed under Chapter 5, agriculture, soil salinization and acidification are major constraints in many irrigation and planned irrigation schemes in Africa. Over-population and resulting soil erosion in watersheds draining into reservoirs has also tended to shorten reservoir lifespans and modification of the hydrological regime by dams has resulted in the loss of fertile sediment being replaced each year on the downstream floodplains.

7.9.6.1 Senegal River

It is estimated that annually, an average 900,000 tons of sediment was deposited on the floodplain between Bakel and Saint Louis (Figure 7.4), 43% of the load as measured at Bakel for an average flood (GFCC, 1980b; 1980d).

The full establishment of irrigated agriculture is still confronted with many difficulties and economically questionable, with average production of rice not exceeding three tons/ha/year instead of the projected 12 tons/ha/year. Moreover, as the delta was a marine bay that gradually filled in with sediment over the last few 1000 years, there is an underlying hypersaline groundwater sheet at about 1 m below average sea level (ASL) stretching to over 200 km inland. Current irrigation practices, usually without drainage systems, seem unsustainable because

of increased soil salinity and large tracts that have already become irreparably damaged for agriculture. The rate of expansion of irrigated agriculture and total production is still far below set targets. For example, in Mauritania, of some 50,000 ha equipped for irrigation at great cost, only about 15,000 are cultivated annually. Some say that about 50% of the irrigation fields has been lost to soil salinization in the basin (Hammerlynck, *et al.*, 2000) (see Chapter 5, Section 5.12.1.3, Irrigation potential, Major Constraints to Irrigation as an Alternative to Production and Chapter 12, Section 12.4.4.1, Impacts of structural adjustment on peasant farmers along the Senegal River).

7.9.6.2 Gambia River

Much of this description is also true for the Senegal River Basin. At the time, little quantifiable data existed as to the degree of soil erosion in the Gambia River Basin. It was believed that the following activities led to wind and rain erosion in the basin (DeGeorges, 1987d):

- **Burning** to clear land for agriculture, for precautionary fires to protect villages from big fires and predators, to improve visibility for hunting, to improve dry season grazing.
- **Over-grazing**
- **Deforestation**, see Chapter 5, Section 5.9.4.7, Deforestation in savanna environments - Deforestation in Senegal Linked to Charcoal Making, Over-Population and Declining Fallow Periods.
- **Farming steep slopes**, as fallow periods disappear and people are forced onto more marginal lands.
- **Clearing land of all soil cover** right before the rains for agricultural purposes.

Indirect estimates of erosion through sedimentation in the Gambia River Basin indicate 50-100 metric tons of sediment/km²/year (Olivery, 1983 *In: DeGeorges, 1987d*). Though considered low compared to more intensively cultivated areas of Africa, the soils of the Gambia River Basin are thin and thus erosion might be considered high; this needs further study. Increased deforestation and farming on marginal land associated with increasing human populations risk to increase soil erosion and the life span of proposed dams, as well as the productivity of the lands.

7.9.6.3 Nile River, Aswan High Dam

Before the construction of the Aswan High Dam, the Nile River carried an average of 124 million tons of sediment to the sea each year, depositing an additional 9.5 million tons on the floodplain and delta as an aid to traditional recession agriculture. Today, 98% of the Nile's silt drops to the bottom of the Nasser Reservoir. As a result of the Aswan High Dam acting as a major silt trap, the loss of silt, low in nutrients, but rich in silica, aluminum, iron and other trace elements, has had a serious effect on Egyptian agriculture, requiring large inputs of artificial fertilizers and a long-term decline in soil trace elements. Each year the silt also added 1 mm to the depth of the soil on the floodplains. This soil loss is particularly significant in the delta, which constitutes 67% of Egypt's cropland, the delta virtually disappearing, and losing 5-8 m/year. Soil exhaustion and salinization linked to the loss of silt, annual flushing and expansion of perennial agriculture, the long-term sea rise in the Mediterranean from global warming and the subsidence of the Egyptian coast add to this crisis (McCully, 2001).

7.9.7 Impacts on Floodplain Irrigation “Recession Agriculture”

Unless there are artificial flood releases from high dams, which in Africa is rare, traditional production systems associated with floodplains (e.g., recession agriculture, dry season pasture for wildlife and livestock and fisheries) are lost both due to a lack of flooding and due to conversion of habitat to irrigated perimeters; often the rural producer loses control of his/her land to an outside elite which moves in for a profit.

7.9.7.1 Senegal River

Seck (1991 *In: Boone, 2003*) estimates that for an average flood only 100,000 ha was traditionally cultivated on both sides of the river.

“Traditionally, the parts of the floodplain that had been under water for 45 days [Note: Bossard (1999) estimated pre-dam floods lasting from a couple of weeks up to four months, Koopman (2004) estimated six to eight weeks, while GFCC (1980b; 1980d) calculated land available for recession agriculture as any area inundated for 30 days or more] at least could be cultivated without any other intervention but planting seeds when the waters receded. Fertility was maintained by the clays and silts that sedimented from the floodwater, and by the dung left by animals that had grazed the floodplains during the dry season. Though the productivity per ha rarely exceeded 1 ton per year, the low labor and capital input and the hundreds of years of experience transmitted through the generations made this exploitation system rather performant, especially for the rural poor. Even now, sedentary agriculturists that have converted to rice farming continue to practice recession agriculture as an extra source of food security whenever the floods released from Manantali allow. A major problem is that the land available for this sustainable type of agriculture is insufficient, not only because of population growth and reduction of flood height but also through the change in land ownership structure. Many of the best soils have been converted to large-scale irrigation plots and concomitantly their ownership has

‘moved out of the valley’ (that is taken over by rich outsiders who can afford inputs). This has in some cases led to serious social conflict. A positive development has been the establishment of small-scale market gardening along the new permanent freshwater courses” (Hamerlynck, *et al.*, 2000).

Boone (2003) goes into some detail on the disenfranchisement of local farmers by local and outside elites as irrigation began taking over (see Section 7.10.5.1, Senegal River). Artificial flooding is discussed in Section 7.11.7.1, Senegal River.

7.9.7.2 Gambia River

Structural scenarios, which included the Balingho Anti-Salinity Barrage, would result in loss of existing/potential tidal swamp rice habitat from inundation by the Balingho Reservoir and/or modification of tidal action:

- 1) Loss of existing tidal swamp culture in Balingho inundation zone, major adverse, long-term.** This was estimated to be 12,756 ha +/- 2,078 (Harding & DeGeorges, 1987). At the time, this was estimated to be 49% of the current rice land in the Gambia (University of Michigan, 1985a). In an earlier estimate, 9,000 ha were identified as existing swamp culture (Cueto & Webb, 1987 *In: Samba & DeGeorges, 1987a*). University of Michigan (1985c) estimated 11,000 ha.
- 2) Loss of potential swamp culture in the Balingho inundation zone, major adverse, long-term.** It was predicted that 40,000 ha of potential improved swamp would be permanently lost within the inundation zone of the Balingho Barrage (Cueto & Webb, 1987 *In: Samba & DeGeorges, 1987a*).
- 3) Loss of existing rice production upstream of Kuntaur (upstream of inundation zone) from loss of tidal action.** An estimated 5,600 ha of

tidal swamp culture habitat was projected to be lost (Cueto & Webb, 1987
In: Samba & DeGeorges 1987a)

- 4) Loss of potential rice production upstream of Kuntaur from loss of tidal action.** An additional potential of 9,089 ha of tidal swamp agricultural upstream of Kuntaur would be lost due to elimination of tidal action (Cueto & Webb, 1987 in Samba & DeGeorges, 1987a).
- 5) Loss of actual and potential tidal rice culture below Balingho.** The University of Michigan (1985c) study estimated at the time that there were 1,930 ha in swamp culture. It is believed that because of the salinity gradient, there would be marginal room for expansion.
- 6) Projected loss of dry season grazing area.** It was projected that 40,550 ha of dry season grazing area would be permanently lost on the North Bank, Lower River and McCarthy Island divisions as a result of inundation by the Balingho Barrage's reservoir (Carney, 1984 *In: Samba & DeGeorges, 1987b*).

Another important factor that must be brought out here is that when agricultural schemes go from subsistence, such as swamp culture undertaken by the 43,000 women, to intensive cash oriented agricultural schemes as was being planned, men tend to displace women in the work force (Samba & DeGeorges, 1987b). Similarly, Turner (2004, *In: Fabricius, Koch, Magome & Turner, 2004*) indicates that women tend to be most heavily involved in and dependent on small-scale subsistence oriented wild resource collection but tend to be displaced by men when this resource collection becomes commercialized (e.g., timber, wildlife, etc.). A classical example is the Jahaly-Pacharr irrigation scheme in the Gambia (Pottier, 2005 *In: Acts, 2005*) that would likely see further disenfranchisement of women as commercial irrigation comes on line.

7.9.7.3 Zambezi River Floodplains

Kariba Dam, Zambezi River

As described under the section on displacement of people, inundation by the reservoir resulted in the Ba-Tonga losing the floodplains necessary for cultivation of giant sorghum (see Section 7.9.1.3, Zambezi River).

Cahora Bassa Dam, Upper Catchment Mozambique, Zambezi River

In the “upper catchment near Cahora Bassa Reservoir, agricultural production was also closely tied to and dependent on the Zambezi River. Waters from the flooding river inundated the banks of the Zambezi during the rainy season, beginning in December and ending in March. When the water receded, they left a rich deposit of nutrients along the shoreline. In lowland areas, this spillover extended, depending on the locale, over a several kilometer stretch of land. Tawara and Tonga peasants through this region stressed that these rich dark makande soils of the floodplains were the most desirable agricultural sites in the region. They distinguished the floodplain makande soils from the more common sandy, rocky ntchenga soils, which did not retain water and were difficult to farm. Given the low and irregular rainfall in the Tete region (600 mm per year), access to the river-fed makande soils was critical to insure household food security. From the interviews, it became clear that the utilization of river-fed fields was an integral part of a complex and highly adaptive indigenous agronomic system, which dated back over several centuries. Drawing on rich repertoire of farming practices, born out of years of trial and error and detailed micro-ecological knowledge” (Beilfuss, *et al.*, 2002).

These areas were lost with the inundation of these floodplains by the reservoir.

Cahora Bassa and Kariba Dams, Zambezi Delta, Mozambique

The Lower Zambezi Valley supports more than one million people who directly depend on the Zambezi River for part of their livelihoods (Davis, *pers comm.*; Beilfuss, *et al.*, 2002). Traditionally more than 350,000 people depended on the

floodplains of the Zambezi Delta, practicing recession agriculture, hunting, fishing, etc. (Beilfuss, *et al.*, 2002). Thus, the lives of the people and the food they depended on were regulated by the annual floods of the Zambezi, as is the case over much of Africa's floodplain ecosystems. A variety of floodplain crops were grown, including corn, vegetables, sweet potatoes and beans with at least two harvests per year, a main harvest - known locally as *tchaca* - during the wet season between October and January and a second harvest - called *mulope* - during the dry season between April and June (Beilfuss, *et al.*, 2002).

Traditionally, high ground was farmed in the wet season and the floodplain in the dry season. Flood recession agriculture provided a safety net during drought years when upland crops failed (UTIP, 2002). The Cahora Bassa (Isaacman & Sneddon, 2000), Kariba and Kafue Dams turned the Lower Zambezi into a regulated river; the principle function of the Cahora Bassa being to provide cheap energy to South Africa (Isaacman & Sneddon, 2000).

By 1975, with the operation of the electrical turbines, the transformation of the river's annual cycle was complete from a punctuated, season-specific flow regime with a regular pattern of flood timing, magnitude and duration to one with irregular floods, relatively constant flow rates and unpredictable high flow durations – without regard for the agricultural cycle (Isaacman & Sneddon, 2000). For instance, occasional out-of-season drawdown releases from Cahora Bassa have wiped out crops along the length of the main stem of the Zambezi River and along the Catarina, Chinde, and Mucelo distributaries (Beilfuss & dos Santos, 2001). From the Shire confluence down to the Zambezi Delta at Luabo, because of the irregular floods, farmers are forced to cultivate their crops and gardens on rainfed uplands far from the river during the wet season. Farms in the lower floodplain and on the islands are periodically washed away by unexpected floods. At Mopeia, much of the farming land formerly used for a double crop of rice has been abandoned, the floodplain being used only once a year for sweet potatoes. In

several areas in the lower reaches of the Zambezi, floodplain farmers have resettled close to the main stem Zambezi to cultivate crops in the narrow band of alluvium that is inundated each year, believing the Cahora Bassa Dam can control large floods (Beilfuss, *et al.*, 2002 & UTIP, 2002). This has led to a significant increase in flood risk and flood damage when large floods occur, such as the 1978 flood, the 2000/2001 Zambezi River flood that killed 700 and displaced 500,000 (NASA, 2008) and the 2007 flood that killed 45 people and left 285,000 homeless from torrential rain and hurricanes (Mangwiyo, 2008). In 2008, early rains, primarily in the Zambezi Basin forced releases from Cahora Bassa dam, flooding the delta and resulting in massive loss of crop production for a second year, and displacement of about 62,000 people as of January 13th (NASA, 2008) and 76,000 by January 22nd (Robertson, 2008). Even floods that are moderate by historical standards, such as the 1989 and 1997 floods, resulted in extensive flood damage because of new settlement patterns. The loss of recession agriculture, along with the loss of the floodplain fishery, has resulted in chronic food insecurity for tens of 1000s of people living in the riparian districts of Morrumbala, Mopeia, Mutarara, Caia and Chinde (UTIP, 2002).

The only agricultural area in the alluvial plains that appears immune from irregular flow is the high rainfall area of the Zambezi Delta coastline, which receives about 1200-1400 mm rainfall per annum, discharge from the Zambezi River and perennial runoff from streams rising on the Morrumbala Plateau (north bank) and Cheringoma Plateau (south bank). The reduction of large flooding events may be contributing to soil salinization in this region (Beilfuss, *et al.*, 2002).

7.9.7.4 Waza Logone Floodplain, Cameroon

This area receives between 500-600 mm of rainfall annually, with crop production failing one in three years, which results in chronic food insecurity, in turn

exasperated by the diverse loss of food as the result of reduced flooding from the SEMRY scheme. A census shows that 148,323 rural residents (24,720 households) in 555 villages live in the Waza Logone region of which 25% have agriculture as their main activity and 34% as a secondary activity. Traditionally, planting occurred as follows (Loth, 2004):

- June, fields ploughed and sowed with red and white millet, vegetables and cotton;
- Red millet harvested in October;
- Nursery plants of dry season millet transplanted end of September – harvested in February; and
- Rice sown in July and nursery plants transplanted in August – first rainfed, then irrigated with floodwater – harvested in February.

The estimated losses to agriculture from the Maga Dam/SEMRY project are estimated at Euros 340,000/year (US\$ 401,200/year) (Table 7.19), mainly from decreased flooding and the lost potential for floating sorghum and rice and recession sorghum (Loth, 2004). Additionally, the total loss of produce is estimated at 50% annually from pests such as the red-billed queleas (*Quelea quelea*), insects and wildlife for those living near the Waza Park, and at times excessive flooding.

7.9.7.5 Kainji Dam, Nigeria

Floodplain yam production fell by 100,000 tons after dam completion in 1968 (McCully, 2001).

7.9.7.6 Nile River, Aswan High Dam

See Section 7.9.6.3, Nile River, Aswan High Dam.

7.9.7.7 Pongola River, South Africa

“In the late 1960s the Pongolapoort dam was constructed on the Phongolo River in north-east South Africa near its borders with Swaziland and Mozambique. The reservoir was filled in 1970 with a view to irrigating 40,000 hectares of agricultural land for white settlers, with no provision for hydropower generation. No assessments were undertaken of impacts of the impoundment on the floodplain where 70,000 Tembe-Thonga people were dependent on recession agriculture, fishing and other wetland resources nor on the biodiversity of the Ndumu game reserve” (Acreman, *et al.*, 2000).

7.9.8 Impacts on Nutrition

The bottom line is that development schemes are supposed to improve peoples' lives by eliminating poverty and improving nutrition and health. Improved nutrition is a very good indicator of how successful a development program has been in achieving or not achieving its goals. The record speaks for itself.

7.9.8.1 Senegal River

The projection of impacts of dams on nutrition in the following tables assumes that the rate of conversion of land to irrigation continues as projected and that an artificial flood will continue for 15 years. The importance of traditional production systems, (1) recession/*waalo* farming, (2) *dieri/jeeri* farming (rainfed), (3) herding and (4) freshwater/saltwater fisheries, in 1980 prior to dam construction cannot be denied, as these make up 75% of the caloric intake and 92% of the protein intake within the Senegal River Basin (Table 7.21).

Table 7.21: Summary of projected, available amounts of nutrition from agricultural products on an annual basis with implementation of the proposed plans of development in the Senegal River Basin

Table 7.21 Cont.: Summary of projected, available amounts of nutrition from agricultural products on an annual basis with implementation of the proposed plans of development in the Senegal River Basin

	1980				2000				2028			
Sources	Calories	% of Total	x 10 ⁷	Total Grams	Calories	% of Total	x 10 ⁷	Total Grams	Calories	% of Total	x 10 ⁷	Total Grams
Saltwater Fisheries	1,400	1	240	4	5,320	2	912	13	14,000	3	2,400	14
Total	96,738	100	5,808	100	254,834	100	10,583	100	465,908	100	17,239	100

- 6) Saltwater equates to marine fisheries whose importation into the Senegal River Basin would makeup for the loss of riverine fisheries from dams and development. With upwelling phenomenon, large ocean fishery of species whose lifecycles are independent of estuaries.

Source: Extracted from GFCC (1980b) funded by USAID, public domain.

- 7) Assume 100,000 ha rainfed Dieri farming for sorghum and millet in 1980, half under cultivation in 2000 and used primarily for agriculture by 2028.
- 8) In 1980 about 100,000 ha/yr of 374,000 ha flooded 30 days or more placed in recession agriculture & in 2000 about 100,000 ha/yr of 178,000 ha/yr artificially flooded for 30 days or more placed in recession agriculture primarily in corn, niebe (beans) and sorghum until 2002 when artificial flood (required flow at Bakel of 2,500 m³/sec from August 15 – September 15) discontinued. By 2028 on average of 64,000 ha flooded for 30 days or more only 47,000 ha in recession agriculture due to agricultural development, flow control & loss of artificial flooding with flooding virtually disappearing in valley between Bakel and Dagana during smaller than average floods.
- 9) In 1980 estimated 2,066,000 cattle equivalents by adding goat/sheep numbers (2,524,000) divided by 7 and adding to cattle numbers. Decrease in cattle units to 2,057,000 and 2,042,000 but carcass weight increases under modern agriculture (28,250-38,250 ha in forage of 255,000 ha in pumped irrigation) from 120 kg to 190 kg/carcass. Also includes pig and fowl production.
- 10) In 1980, 12,000 ha of pumped irrigation 100% in rice (64,400 metric tons) but by 2028 with 255,000 ha in production while rice still dominants (406,200 metric tons) metric tons from other crops also includes wheat (132,600), corn (222,300), sorghum (315,000), beans (3,800 dry weight) and vegetable fruit (256,800). In 2000, 117,000 ha, same crops as 2028 at about 50% the yield in metric tons.

Source: Extracted from GFCC (1980d) funded by USAID, public domain By principal author who helped prepare original table

Actual consumption of cattle for cultural reasons may have been much less than shown, but was projected to increase in importance as the basin entered into a cash economy. One could also project that if traditional food production systems were wiped out – as has happened – without replacing them with production from

the planned irrigation, there could be an increase in livestock consumption as people would enter into a survival mode or sell livestock to obtain money to buy food that could no longer be produced. Of course, wiping out the dry season forage habitat from reduced flooding without replacing it with high value forage as projected from the irrigated perimeters could also have resulted in a drastic decline in livestock as a nutritional or income source.

On the other hand, if in fact livestock were not consumed to the degree applied in the analysis, then the other traditional systems would become that much more nutritionally important if irrigation would not take off.

Even with the projected increase in irrigation offsetting the loss of these traditional production systems, caloric deficiencies in the Senegal River Basin were projected to become a problem by 2028 during peak development of the irrigated perimeters (Table 7.22). Due to the exponentially expanding human population, food demand by 2028 would exceed the linear growth of agricultural production as projected. It was projected that the quality of the diet as measured by protein intake would remain adequate while deficiencies in the quantity of food consumed, as measured by caloric intake, would return to deficit levels. This deficiency was evident even without stratification of the populace by age groups, even though caloric deficiencies are more common in younger age groups.

It was projected that caloric deficiencies (undernourishment) may ultimately result in protein malnourishment even though adequate supplies of protein might be consumed. This results from proteins being used as an energy source in place of much needed calories. Proteins are lost as building blocks for growth, repair and preservation of the body and bodily functions.

Table 7.22: Summary of projected, available caloric and protein intakes for the population of the Senegal River Basin on an annual basis with implementation of the proposed plans for development

	1980	2000	2028
Population	1,649,500	2,901,100	6,274,500
<u>Calories</u>			
Total Available (x10 ⁷)	96,738	254,834	465,908
Total Desirable ¹ (x10 ⁷)	138,476	243,547	526,744
Deficit (-)/Gain (+) (x10 ⁷)	-41,738	+11,287	-60,836
Daily Per Capita Availability	1,607	>/= 2,300	2,034
<u>Protein (Grams)</u>			
Total Available (x10 ⁷)	5,808	10,583	17,239
Total Desirable ² (x10 ⁷)	3,974	6,989	15,115
Deficit (-)/Gain (+) (x10 ⁷)	+1,834	+3,594	+2,124
Daily Per Capita Availability	>/= 66	>/= 66	>/= 66

- 1) Assume minimum value of 2,300 calories per capita per day for projected basin populations
- 2) Assume average value of 66 grams of protein per capita per day for projected basin populations.
- 3) Human population growth rate projected at 2.3% per annum
- 4) By 2028, rice and wheat would have to be imported into the basin
- 5) Key assumptions are that a) programmed levels of agriculture proceed at scheduled rate of implementation, b) the annual crop yields assume proper management of irrigated perimeters, c) prior to export out of the basin, local dietary needs would be met first.

Source: Produced by principal author for GFCC (1980b), funded by USAID, public domain

What has actually happened is that the traditional systems have been virtually wiped out and that irrigation has failed to come anywhere near the projected 255,000-375,000 ha. The proposed artificial flood as of 1999 has not taken place to the degree planned, with the result that yields from recession agriculture and riverine/estuarine floodplain fisheries are minimal. So far only about only about 100,000 ha have been brought under irrigation, with only about 2,000 ha being added per year (Bosshard, 1999; World Bank, 2001; WEC, 2003). Some say that about 50% of the irrigation fields have been lost to soil salinization in the basin

(GEF, 2002). The dams and dikes have reduced traditional grazing lands from 80,000 ha to 4,000 ha in the valley (GEF, 2002).

Even if artificial flooding could bring an average of 50,000 ha/year into recession agriculture production (see Section 7.10.7.1, Senegal River) that was the GFCC 2028 scenario (see Table 7.21, footnote 8), without going into a detailed analysis, it can be seen that there would be an immediate food crisis both with regard to caloric and protein intake, both falling into deficit categories. It must be presumed that the deficit in the near future can only be mitigated by:

- 1) Out migration
- 2) Food aid and/or
- 3) Remittances sent from family living in Dakar or overseas.

Out migration from the Senegal River Basin by males in search of employment has been a factor since the 1940s, peaking during the drought of the 1970s because of a failing economy and desertification. In 1980, over 90% of the foreign labor in France from the Sahel came out of the Senegal River Basin. It was projected that without the OMVS development scheme (or implying if it failed) 100,000 migrants/year would leave the basin by 1980 and 850,000 migrants/year by 2028 (GFCC, 1980b). In 2006, it is assumed the figure of out migration falls between these two figures. In fact, since the dams, the net result of declining food production from the slow pace of irrigation expansion and the rarity of useful floods has resulted in out-migration by young males, households depending upon remittances to buy food they no longer produce, an increase in malnutrition especially among women, children and ethnic minorities and increased vulnerability to respiratory and parasitic diseases from declining nutrition (Finger & Teodorou, 2003). One must wonder what percentage this has

contributed to Senegalese fleeing to the Canary Islands via unseaworthy boats, many dieing along the way, in hope of reaching France and a better life?

The GFCC environmental assessment (1980b) went on to say that if the population continued to grow as expected to over 6 million people in the river basin, and yet agricultural production remained at 1980 levels, the daily per capita caloric intake rate could fall to as low as 424 calories/person/day and protein as low as 26 grams/person/day. This would mean severe under- and malnutrition of the basin's inhabitants and an increased susceptibility to disease. From the failed irrigation schemes and the destruction of traditional production systems, one would have to assume that by the late 1980s or at the latest early 1990s a nutritional crisis would exist unless there was an increased out-migration, mitigation was successful and/or remittances from family working elsewhere helped provide purchasing power to buy imported foods.

The switch from local grain to rice production and the reduction of fish consumption have also had negative impacts on the diet of the local population. A 1994 study of villagers in Senegal and Mauritania financed by USAID determined that their health has deteriorated. The study is convinced that before the construction of the dams, the production of traditional food recession crops provided a more varied and healthier diet. The local population insists that it is because of their present diet, made up primarily of rice, that they are weaker and have more health problems than before. Rice consumption is not only a consequence of the new dam, but also seems to have become a cultural preference in the Senegal Valley (Bosshard, 1999). McCully (2001) states that rice consumption doubled in eight years since the dams were finished, but that the nutritional status of the people in the valley declined since the variety in their diet (millet, sorghum, maize, black-eyed peas) had fallen between 30 and 90%. Consumption of fish, meat and dairy products had also fallen.

7.9.8.2 Gambia River

The following compares a high dam scenario only versus a high dam linked to the Balingho Anti-Salinity Barrage and the impacts this will have on rice production and nutrition in the Gambian portion of the basin where most of the rice is currently produced and would be produced if dams were built. While a high dam only option would allow the development of both irrigation and improved tidal swamp culture, any structural alternative with the Balingho Anti-Salinity Barrage would be catastrophic to the local people (Table 7.23).

Assuming that Balingho was hooked into a high dam that permitted irrigation that produced 360,000 metric tons of rice (Table 7.23) in the Lower River, the net production from a two dam scenario would be 287,757¹⁸³ tons of rice that could assure 2,300 calories/day as a minimal requirement for a healthy adult (GFCC, 1980b) theoretically to +1,191,185 people compared to 432,243 metric tons of rice from a high dam scenario only (see Table 7.20) that could assure minimum daily caloric requirements to +1,786,778 people/year. Thus, theoretically, the high dam only scenario could feed an additional 595,593 people in the estuary and Lower River where the majority of the people reside. This has not accounted for the additional irrigation in the Senegal and Guinean portions of the basin, which will vary slightly with each dam. The purpose here is to demonstrate that regardless of the high dam, in the Gambian portion of the basin, any high dam with the Balingho Anti-Salinity Barrage will result in significantly less food being produced than a high dam only scenario. Thus, other than for construction profits for dam building companies, kickbacks for politicians and a bridge to control the secessionist movement in the Casamance (see Section 7.8.5, Politics of Proposed

¹⁸³ 360,000 tons from irrigation - 72,243 tons lost from the Balingho Barrage = 287,757

Dams on the Gambia River), it is impossible to understand how anyone could opt for the Balingho Barrage as part of any dam scenario! Learning from the Senegal experience, if irrigation development does not attain projected goals and traditional swamp culture is wiped out, the high dam scenario at least allows residents to continue producing via traditional systems.

Table 7.23: Projected loss of annual rice yield potential in the estuary and Lower Freshwater River Zone with Balingho Barrage

Location	Ha (1)	Yield (Metric Tons Rice) (2)	Protein Gain From Rice (gm) (3)	Carbohydrate Gain From Rice (Calories) (4)
Pumped Irrigation Upstream of Kauntaur	+40,000	+360,000	+238 x 10 ⁸	+12.6 x 10 ¹¹
Improved Tidal Rice Balingho to Kuntaur	-49,000	-56,350	-37 x 10 ⁸	-2.0 x 10 ¹¹
Tidal Rice Upstream of Kuntaur	-9,089	-14,542	-9.6x 10 ⁸	-0.5 x 10 ¹¹
Tidal Rice Tendaba to Balingho (Mangrove Soils)	-1,930(5)	<u>-1,351</u>	<u>-0.9 x 10⁸</u>	<u>-0.05x10¹¹</u>
Total Loss of Rice Production		-72,243	-47.5 x 10 ⁸	-2.6 x 10 ¹¹
Net Gain in Rice		+287,757	+191 x 10 ⁸	+10 x 10 ¹¹

(2) Pumped Irrigation 9 tons/ha/ year. Swamp Culture: 1.6 tons/ha/year non-mangrove soils and 0.7 tons/ha/year mangrove soils (Use average of 1.15 tons/ha/year below Kuntaur since one cannot separate mangrove from non-mangrove and 1.6 tons/ha/year upstream of Kuntaur where mangroves do not exist) (Samba & DeGeorges, 1987a)

(3) 6.6 grams (gm) protein/100 gm of rice, HEW (1968 In: Samba & DeGeorges, 1987b)

(4) 350 calories/100 gm of rice, HEW (1968 In: Samba & DeGeorges, 1987b)

(5) University of Michigan (1985c)

Prepared by principal author

The Balingho would have to be linked to a high dam as noted.

Add in what would appear to be a significant loss of fish (Section 7.8.7.2, Gambia River) and dry season grazing for livestock (Section 7.8.9.2, Gambia River) as a result of the Balingho Anti-Salinity Barrage and one is faced with a food crisis, which unlike a drought, would be permanent in nature. Also, as noted under the Senegal River case study, a carbohydrate deficiency can result in a protein deficiency from forcing the body in trying to survive to draw on muscle tissue as a source of energy.

7.9.8.3 Cahora Bassa Dam, Mozambique, Zambezi River

Anderson, *et al.*, (1990) believe one of the reasons poaching is up in the Marromeu Swamps is due to a decline in other sources of food, which artificial floods would bring back in the form of freshwater fish production, recession agriculture, dry season grazing and even shrimp production, helping people find a more diverse source of protein which could take the pressures off the wildlife within this game reserve. In addition, increased flooding would likely make access into the Marromeu Complex by poachers during the wet season more difficult, while operational trophy hunting camps during the dry season would serve as a second deterrent. A third aspect would be to get local communities more actively involved in co-management of the area, even allowing traditional hunting and fishing within the area but in a controlled manner.

Estimates made within Mozambique cost the lost power output from Cahora Bassa to restore a mimicked natural flood regime at US\$ 20 to US\$ 30 million/year or some 10% to 15% of the value of its power generation. Early estimates put the gain in agricultural, fishing and aquaculture, wildlife and tourism in the delta at higher than that loss of power (WCD, 1999) (see Section 7.10.7.3, Kariba and Cahora Bassa Dams, Zambezi River).

7.9.9 Impacts on Health

Reservoir areas become foci of disease during and after construction. Also, unless people are healthier and better fed as a result of dam construction, in a weakened state they become more susceptible to succumbing to disease because of weakened immune systems.

7.9.9.1 Senegal River

When the Diama and Manantali Dams were filled, an epidemic of Rift Valley Fever (mosquito vectors) occurred, schistosomiasis (aquatic snail vector) prevalence rates reached record levels and riverside inhabitants experienced diarrheal disease, malnutrition and malaria, despite experiences with transmission of these diseases from earlier African dams (WCD, 2000). The Rift Valley fever outbreak began in October 1987, appearing for the first time in West Africa, killing 300 people in Rosso, Mauritania. The outbreak appeared at a time when mosquitoes were unusually abundant due to the recent filling of the Diama Dam and the subsequent increase in irrigated rice fields (McCully, 2001).

By 1994, rates of infection of intestinal schistosomiasis (pre-dam only urinary schistosomiasis was a problem) ranged from 25-82% of the people living near the lower Senegal irrigation schemes (McCully, 2001). Certain villages near the reservoir and in the valley reported a prevalence of schistosomiasis of close to 100% (Bosshard, 1999).

"The dramatic increase in incidences of malaria and schistosomiasis in the Valley since the Manantali and the downstream Diama Dams were built, now claim 8,000 lives a year.
 The huge Senegal Sugar Co. near the Diama Dam in the lower valley is the focus of the worst bilharzia (schistosomiasis) epidemic ever seen in Africa. More than 50,000 plantation workers are infected. In 1986, before the Diama Dam came into operation, there were no cases of bilharzia" (Sevunts, 2001).

In the past, seasonal fluctuations in flows and salinity helped keep the disease-bearing snails of schistosomiasis from taking hold (Pottinger, 1997). On the positive side, the Manantali Dam has eradicated River Blindness -

Onchocerciasis, around the inundation zone and reduced the incidence downstream (McCully, 2001).

7.9.9.2 Gambia River

The major impact in the Gambia would be from the Balingho Barrage (University of Michigan, 1985d; Samba & DeGeorges, 1987b):

- **Anemia and other nutritional diseases.** Although gains can be expected from irrigated agriculture in food supplies, it would be a long time before the loss of traditional agricultural production and projected losses in fish yields would be made up, if ever, as a result of projected major, long-term, adverse, irreversible impacts from the Balingho Barrage.
- **Urinary schistosomiasis, *Schistosoma haematobium*.** The reduction of salinity and the elimination of tidal action creating pond-like conditions with the possibility of infestation by water hyacinth would create ideal conditions for the proliferation of the snail host, *Bulinus truncate guernei*. Major, adverse, long-term and irreversible.
- **Intestinal schistosomiasis, *Schistosoma mansoni*.** The Balingho Reservoir was projected to provide an ideal environment for the proliferation of the snail host, *Biomphalaria pfeifferi*. Major, adverse, long-term and irreversible.
- **Malaria.** With the creation of a freshwater reservoir, it was predicted that the more efficient mosquito vector, *Anopheles funestus* would replace the salt flat breeding *A. melas*. *A. funestus* has a longer flight pattern and is a more efficient vector than *A. melas*. This would increase the incidence of malaria among residents living in the vicinity of the Balingho Reservoir. Major, adverse, irreversible.

Regardless of the scenario, urinary schistosomiasis was projected to intensify with the expansion of irrigated agriculture, providing additional habitat for *Bulinus globosus* (*B. jousseaumei*) along with the spread of malaria (University of Michigan, 1985d). As agriculture intensifies, it was projected that the use of pesticides would significantly increase. Organo-phosphate pesticides that are neuro-toxic would pose a direct health risk to handlers. Long-lasting in the environment, organo-chlorines would risk to bio-accumulate in fish and animal flesh, causing indirect health risks to basin residents who consume the flesh as a protein resource (Samba & DeGeorges, 1987b).

7.9.9.3 Kariba Dam, Zimbabwe/Zambia, Zambezi River

The Kariba triggered an epidemic of sleeping sickness (trypanosomiasis) amongst settlers who moved up the Sengwa River on the Zimbabwe side. Bilharzia and malaria were prevalent before and after. An outbreak of cholera in the two most densely re-settled areas of Lusitu and Siameja in Zambia would appear to be related to population pressure, inadequate and poor quality water supplies and environmental degradation; all linked to resettlement (WCD, 1999).

7.9.9.4 Cahora Bassa Dam, Zambezi River

As would be expected, “near Cahora Bassa Reservoir, water borne parasitic illnesses such as schistosomiasis and malaria now pose new health threats to the population since the dam was constructed” (Beilfuss, *et al.*, 2002).

7.9.9.5 Lesotho Highlands Water Project

HIV is believed to have made inroads into the isolated mountain communities via construction workers, of which 1 in 20 (5%) tested HIV positive along with 1 in

120 (0.83%) in nearby villages (McCully, 2001). Thamae & Pottinger (2006) place the incidence as 0.5% in villages around the dam and 5.3% in the dams' work camps in 1992. By 1999, tests of antenatal women living around Katse Dam indicated 22% were HIV positive.

7.9.9.6 Akosombo Dam/Volta Reservoir, Ghana

All reservoirs have become infected with *Bulinus spp.* snails, vectors of urinary schistosomiasis. Around the Volta Reservoir, urinary schistosomiasis increased from 10% of the riverine villages in 1966 to 90% in children living near the new reservoir in 1969. A World Health Organization (WHO)/UNDP schistosomiasis eradication program spraying molluscicides and treating infected people halved the incidence of this disease in treated people between 1975 and 1981, but still left 40% of the people in the project area infected. It only covered 60 km along a 5,000 km shoreline of the Volta Reservoir. The Volta Reservoir has flooded out large areas of blackfly breeding grounds, vectors for "river blindness" or onchocerciasis, but worsened the disease downstream because of blackfly breeding habitat created by the spillway and altered downstream flows (McCully, 2001).

7.9.9.7 Nile River, Aswan High Dam

"Since construction of the High Aswan Dam, infections of the more dangerous intestinal schistosomiasis have risen markedly, especially in the Nile Delta, possibly because the increased salinity of water in the delta favors the vector, *Biomphalaria sp.* snails which carry *Schistosomiasis mansoni* (intestinal) over the *Bulinus spp.* snail that carries *S. haematobium* (urinary). The loss of the flood, which once swept the snails out to sea, and the explosion of freshwater aquatic vegetation in the irrigation canals provided habitat for the snail vector. In 1977, a mysterious hemorrhagic disease, later identified as Rift Valley Fever-a viral disease, broke out near the Aswan. About 18,000 cases were recorded and 600

people died. Previously, it was only known in livestock. It is believed to have started as an outbreak among livestock in northern Sudan, and then spread to Egypt via human in-migration or wind-blown mosquitoes. The Nasser Reservoir provided habitat for mosquitoes which served as vectors of the virus" (McCully, 2001).

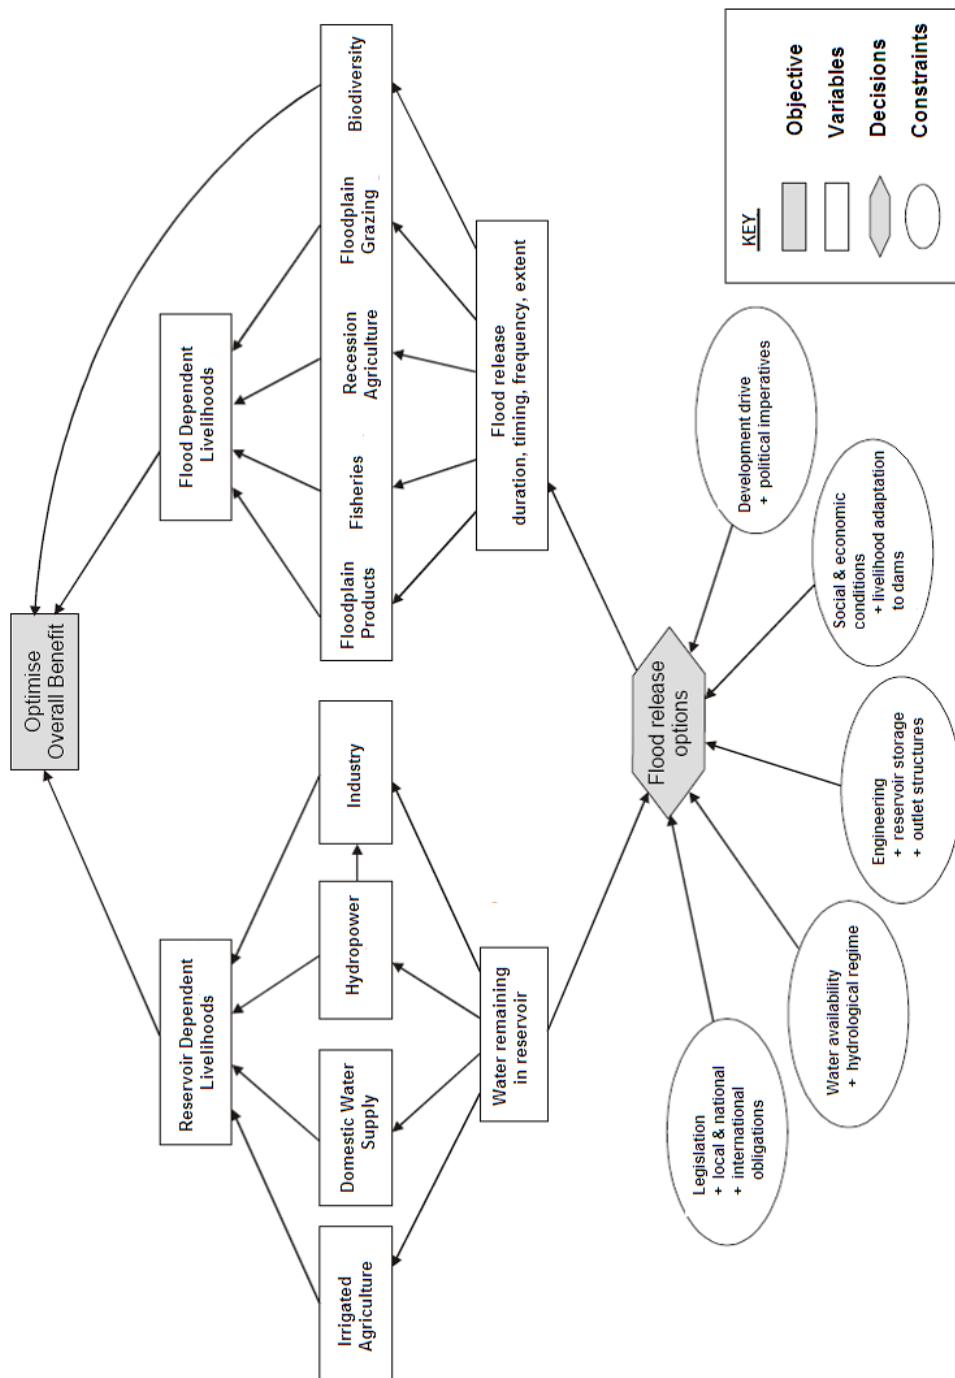

7.9.9.8 Kossou, Cote d'Ivoire

The reservoir flooded large areas of blackfly breeding grounds, vectors for "river blindness" or onchocerciasis, but worsened the disease downstream because of blackfly breeding habitat created by the spillway and altered downstream flows (McCully, 2001).

7.10 PLANNING AND MITIGATION

Mitigation is easier said than done. The problem is often the lack of political will to link technical planning into the political machinery of decision-making. Technical pre-dam planning, through multi-million dollar multi-disciplinary environmental assessments, was undertaken on both the Senegal and Gambia studies, but misused or bypassed. We know what the problems are, and how to solve them, but the will of the politicians is not there. What is provided below is theoretical.

The basis of post-dam planning might be considered the new science of "Restoration Ecology", with a major goal of returning floodplains and estuaries, modified by dams and other hydrological structures, to their traditional ecological and production roles (Adams, 2003 *In:* Adams & Mulligan, 2003). The gains and losses from controlled flooding and the tradeoffs from various uses can easily be modeled (Figure 7.14) and have been such as in the Senegal and Gambia River Basin environmental assessments. Maintaining a downstream hydrological balance is referred to in some circles as "environmental flow".

Source: Acreman, *et al.* (2000), WCD public domain

Figure 7.14: Flow chart depicting competing water uses that must be modeled against gains from controlled flooding

An ‘environmental flow’ is the provision of water within rivers and groundwater systems to maintain downstream ecosystems and their benefits, where the river or groundwater system is subject to competing water uses and flow regulation...Environmental flows are vital for healthy functioning river systems, which in turn are critical for attracting investment, achieving long term economic prosperity and the conservation of biodiversity. Environmental flows work for people as much as for plants and animals (IUCN, 2003).

What obstructs such idealistic approaches are the amoral politics of big money and the complete lack of accountability by consulting firms, donors and politicians, all of whom benefit at the expense of the voiceless rural people of Africa.

The most significant impact of most dams in Africa has been on the downstream floodplain ecosystems. As a result, the Sahelian Wetlands Expert Group (SAWEG) was formed and is linked to the IUCN. SAWEG is a network of floodplain specialists working in the Sahelian region of West Africa. SAWEG currently includes around 100 members (SAWEG, 2001):

- With a wide range of disciplines, including hydrologists, water engineers, biologists, physicists, pedologists, planners, human and animal health experts, ecologists, sociologists, legal experts and agro-foresters; □native to or working in the Sahelian countries of Nigeria, Mauritania, Senegal, Mali, Niger, Chad, Burkina Faso, the Gambia and Cameroon; and
- Representing key organizations, including universities, research institutions (both national and international), government departments, non-government organizations (from local to international, including the International Institute for the Management of Irrigation) and river basin development authorities such as the OMVS (Senegal River Basin

Authority), the Niger Basin Authority, the OMVG (Gambia River Basin Authority) and the Lake Chad Basin Commission.

Similar to the well-known author Sandra Postel in her recent book, Rivers for Life (Postel & Richter, 2003), the SAWEG group is an advocate of returning floodplains to their traditional roles, implying the use of artificial floods from controlled dam releases.

7.10.1 Planning

Sadler, *et al.* (2000) recommend new approaches to river basin planning that are more bottom-up, more inclusive of stakeholders and which adequately address environmental and social issues (Table 7.24).

The Sahelian Wetlands Expert Group (SAWEG) was formed and is linked to the IUCN. The Guidelines and Manual, “Toward the Sustainable Management of Sahelian Floodplains”, were compiled in four years of work by over 60 of the SAWEG experts from West Africa (SAWEG, 2001 with permission of IUCN):

“Planning provides a structured way of solving problems and achieving objectives. It involves viewing the floodplain and its catchment as a single system which has economic, social and environmental components that interact. Planning requires a multi-disciplinary team including experts. The steps involved in planning are described below.

- a. **Bring together key stakeholders.** Develop a process of stakeholder participation; have each stakeholder define his/her core interest rather than rigid viewpoint; develop a process of information sharing among stakeholders
- b. **Collate available information.** Develop a data collection strategy, collect data and set up databases; identify traditional floodplain uses (e.g. recession agriculture, grazing, fisheries, hunting, etc.) and involve local communities in data collection; establish a records center and

publicize its existence; make information available; establish monitoring program.

Table 7.24: Old and new concepts for river basin planning and dam placement	
Old Planning Concept	New Planning Concept
A hydro project is a technical scheme to: <ul style="list-style-type: none"> Provide basic technical infrastructure to improve supply of power/water 	A hydro project is part of an integrated set of technical, environmental and social measures to: <ul style="list-style-type: none"> Cover basic needs of people in a sustainable manner (water, light, power) Accelerate rural development to improve the welfare of people in the region – particularly those directly affected by the project Improve environmental and flood protection Combat global warming
Planning is government responsibility , often assisted by international development agencies	Planning involves many partners/stakeholders: <ul style="list-style-type: none"> Government People affected Non-governmental organizations Private sector developers Financing institutions
Least-cost planning procedure: <ul style="list-style-type: none"> Identify least-cost project to cover power/water needs Carry out unavoidable social & environmental impact mitigation at minimum cost Carry out detailed studies 	Multi-criteria planning procedure: <ul style="list-style-type: none"> Project(s) must be part of sectoral development plan Rigorous study of project alternatives, including the No-Project option Prepare comprehensive comparison matrix showing pros & cons of each alternative from technical, environmental, social, economic, financial, risk & political perspectives Quantify secondary & external costs & benefits as well as risks Reach consensus among stakeholders about overall best alternative to be developed Carry out detailed studies
Public Sector Project: <ul style="list-style-type: none"> Developed & owned by government Funding partly from international development agencies 	Private/Public Sector Project <ul style="list-style-type: none"> Developed & owned by private sector, with or without government participation Finance largely from commercial sources International development agencies act as catalyst for project funding by providing guarantees Access to semi-concessional funding if stringent international guidelines for social & environmental impact mitigation are followed

Source: Oud (1998 *In: Sadler, et al., 2000*), WCD public domain

- c. **Analyze information.** Determine health status of people and animals, hot spots and trends; review existing legislation, local and customary laws; identify thresholds for change; predict impacts of future change, such as climate; indicate uncertainty associated with results.
- d. **Define a range of development options.** Develop a master plan and involve all stakeholders; plan at the catchment scale; define a range of development options; promote restoration of sites whose value has been degraded; always have a do nothing option.

Examples of water related catchment objectives

Overall Objective	Possible Specific Targets
Fisheries	Self-sustaining edible fish population
Wetland grazing	Palatable grasses for resident and migrant herds
Recession agriculture	Seasonal flooding of riparian land
Irrigated agriculture	Controlled water available all year
Water transport	Adequate depth in water courses
Hydropower generation	Water stored in reservoir throughout the year
Water supply reliability,	Quality of supply
Wildlife conservation	Protection of habitats for rare species

Examples of development options

- Intensive irrigation
- Hydropower generation
- Aquaculture
- Desertification control
- Sustainable fisheries
- Small embankment construction to control floodwater
- Restoration of natural floodplain functions
- Establishment of nature reserves and national parks

- e. **Assess the impacts of options.** Undertake environmental impact assessments on all options; consider all impacts at the river basin, regional and international scale; impact assessment should be an integral part of the process; assess health and social implications; ensure that traditional rights are maintained; promote options that are environmentally sustainable; develop alternatives or redesign options that have negative impact on the ecosystem;
- f. **Make decisions.** Take a long-term view; consider who benefits and who loses from an option; mitigate conflicts; use multi-criteria analysis including economic valuation; favor multiple use against single sector projects" (SAWEG, 2001 with permission of IUCN).

7.10.2 Implementation

“Preferred development options should be implemented through the following three guidelines.

- a. **Principles for implementation.** Incorporate the various elements of the river basin’s ecosystems into the implementation; underpinned decisions with best science and technical advice; allow for cross-sectoral considerations in the design of investments and policies; empower stakeholders to contribute to decision making; never do at a higher level what can be done effectively at a lower level.
- b. **Guidelines for implementation** Define and maintain a step by step implementation strategy; establish an effective monitoring and evaluation framework; develop system analysis and indicators of progress and of environmental change in project / program area; establish effective co-ordination mechanisms; define the responsibilities of involved institutions; enhance existing or develop new effective self regulation systems; develop effective mechanisms for conflict resolution, negotiation and participatory planning and implementation; develop clear sets of management instruments” (SAWEG, 2001).

7.10.3 Awareness Building, Institution Strengthening and Training

- a. **“Building awareness for integrated floodplain management.** Develop and implement clear communications strategies both for projects and programs as for general campaigns.
- b. **Strengthening institutions capacity in integrated floodplain planning and management.** Develop NGO capacity to contribute to effective decision making and project development; develop collaborative management agreements between governments and local communities; establish stakeholder groups to permit input to policy development, planning and implementation.
- c. **Training and educating for effective floodplain planning and management.** Training and education efforts should focus on: development of technical expertise; training of staff in functions and values of floodplains; transfer of appropriate technology to local water managers and regional planners” (SAWEG, 2001 with permission of IUCN).

7.10.4 Financing of floodplain development

- a. **“The financial strategy.** Diversify sources of income so as to reduce risk; develop alternate financial strategies in the planning phase of the process.
- b. **Financing from foreign and domestic sources.** Consider radical ideas such as new taxes for water use; work with donors and recipients governments on debt-relief arrangements and develop innovative funding mechanisms, such as debt-for-nature swaps.
- c. **Financing from the private sector.** Develop partnerships between the private sector and government institutions; define and implement legislation, subsides and incentives to control private sector investment” (SAWEG, 2001 with permission of IUCN).

7.10.5 Policy

- a. “Develop the concept of Integrated Water Resources Management (IWRM) and seek support from international organizations.
- b. Develop a national wetlands policy in line with the guidelines provided by the Ramsar Convention and implement **the wise-use concept** promoted by the Ramsar Convention.
- c. In line with Organization for Economic Cooperation and Development (OECD) and Ramsar Convention guidelines, 1996, development agencies must therefore **discourage support of any activities that can damage floodplain functions and services**” (SAWEG, 2001 with permission of IUCN).

7.10.6 Monitoring

Once dams, development schemes (e.g., irrigation) and mitigation (e.g., artificial flooding) are in place, monitoring must take place to allow adaptive management and modification of management interventions that allow impacted communities to mitigate unanticipated adverse impacts or take advantage of unanticipated positive impacts, ecologically, economically and socially.

7.10.7 Realities of Mitigation on the Ground

7.10.7.1 Senegal River

Mitigation is basically a question of political will to partition water flows so as to maintain traditional production systems. GFCC hydrological modeling allowed for such partitioning to take place. McCully (2001) states it best in saying that

“Although discussed as a mitigative measure, to offset adverse environmental and social impacts, artificial floods rarely happen to the degree needed to bring back natural systems, especially in large multi-purpose dams where water use is often in conflict, irrigation and hydro-power being priorities over maintaining the very ecosystems that fed the people and were eliminated by the dams in the first place. In simplest terms, dam operators cannot replicate a wild river, and mitigative measures such as fish culture will not replace natural fish, fish ladders will not allow adequate upstream migrations of spawning fish, tree farms will not duplicate the role of mangroves in contributing to the detrital food chain of an estuary”.

Senegal River Floodplains

The Institute of Development Anthropology (IDA), which in 1987 began a program of research in Senegal, the Senegal River Basin Monitoring Activity (SRBMA), demonstrated that flood-recession crops offered a better return on capital and labor than irrigated farming, while reducing risks to a minimum. They suggested that a permanent artificial flood from Manantali raising the river to the level achieved by a natural flood was justified by the increased production, income and work it would provide, while also protecting the environment. Contrary to what OMVS consultants had claimed, there was no incompatibility between controlled flood releases and the production of electricity. OMVS staff told IDA’s hydrology expert that it was “dangerous” even to ask questions about

the artificial flood, as that might give farmers the idea that they were entitled to it (Adams, 2000b).

With the Manantali Dam, the annual flood has been reduced to an artificial two-week flood compared to normal flooding of up to four months (Note below dam operator estimates 7 weeks of flooding). This short duration would have a major adverse impact on such areas as fish production, groundwater recharge, silt deposition and likely both recession agriculture and pasture production. According to the World Bank, the new hydropower plant will compete with the artificial floods for agriculture and will reduce the flooded area by another 15,000 ha (Pottinger, 1997) to 20,000 ha (Bossard, 1999). The World Bank claims that after hydropower construction, floods will still allow recession farming on an area of at least 50,000 ha, except in very dry years (Pottinger, 1997; Bossard, 1999). There is reason to doubt this statement. Critics argue that the bank's forecast is based on hydrological data, which is outdated and does not reflect the reduced rainfall pattern since the 1970s. On the basis of the flows prevailing since the 1970s, the average flood would only extend to 30,000 ha and there would not be enough water for any flood every third year (Bossard, 1999) compared to the annual average flood of 459,000-549,000 ha without a dam modeled by GFCC. Pottinger (1997) interprets this as an average of 30,000 ha available for recession farming. It is believed that Pottinger's interpretation is more correct. Additional issues that would need to be asked are to what degree flushing by the flood controls soil salinization and what the silt/nutrient/trace element load dropped on the land is before as compared to after the Manantali as a means of maintaining soil productivity?

In 1997, an artificial flood was released close to the hydrograph used as a standard. Satellite images suggest that the area available for flood-recession farming was on the order of 70,000 ha, 45,000 ha on the left bank and 25,000 ha

on the right bank. A rapid survey of the *Société d'Aménagement et d'Exploitation des terres du Delta du Fleuve Sénégal* (SAED) that controlled irrigation on the Senegal River on the Senegalese side, agents and people living near major areas of flood-recession land suggested that this flood was generally satisfactory. Although, it was sometimes judged not to have lasted long enough for satisfactory flooding of low-lying land. It was an improvement over 1996, when there was scarcely any flooding, but distinctly inferior to that of 1995 (Adams, 2000c).

The other problem is the irregularity in flooding. With no announcement, the Diama would be opened and drained, encouraging people to plant maize, beans, calabashes and pumpkins along the banks only to see their work destroyed by a release of water from Manantali (Adams, 2000b). In both 1989 (Adams, 2000c; Adams, 2000d) and 1991(Adams, 2000d), two artificial floods in the same year wiped out farmers' crops planted after the passing of the first flood. OMVS's lack of respect for its promise to maintain an artificial flood is particularly striking, as the Senegalese government's position on this matter seemed to have evolved (Adams, 2000b).

GFCC (1980b; 1980d) estimated 100,000 ha available for recession agriculture under a flow of 2,500 m³/second for 30 days from August 15th to September 15th of each year. Using a minimal flow at Bakel required for a flood, where all rivers join, at 2,500 m³/second during 30 days in August and September, (Adams, 2000a), the Institute for Development Anthropology, in about 1998, assessed the following operational scenarios for the Manantali/Diama Dams, (Adams, 2000c; Adams, 2000d):

- **Scenario 1** gives priority to the needs of agriculture (irrigated and flood recession);

- **Scenario 2** gives priority to electricity generation and the needs of irrigated agriculture (with no flood support); and
- **Scenario 3** takes into account the three main objectives of the dam (supplying water for irrigation, generating electricity and flood support in favor of flood-recession farming).

Based on natural flows for the period 1970-93, which correspond more closely to present circumstances, Scenario 3 would allow 50,000 ha of flood recession farming one year in ten and 40,000 ha every other year, averaging 30,000 ha with some flood recession farming possible two out of three years. This compares to 50,000 ha of flood recession farming one year in three without dams (Adams 2000c; Adams, 2000d). “Scenario 1 yields results very close to 3, because when the river’s rate of flow is weak (as during the period under consideration), there are few releases which cannot be used for energy production” (Adams, 2000c). Scenario 2 would not allow for any artificial flooding.

This compares to the annual average flood of 459,000-549,000 ha modeled by GFCC. Over the period 1946-1971, it is estimated that on average 312,000 ha of low lying land, *waalo*, was flooded every year on both banks of the river, and 108,000 ha cultivated; on the Senegalese side of the river, 65,000 ha were cultivated (IRD-OMVS, 1999 *In:* Adams, 2000d), meaning an average of 43,000 ha cultivated on the Mauritanian side.

The artificial flood would in no way support the estimated 364,132 persons out of a total population of 592,602, who were engaged in flood-recession farming (Adams, 2000a).

According to Acreman, *et al.* (2000), since 1991, floods have been broadly in line with a hydrograph designed to flood 50,000 ha (believe means area in recession

agriculture, left and right banks total) and exceeded it in years of good rainfall, while avoiding damaging second peaks, averaging 58,000 ha (believed left and right banks) under recession cropping, an increase over drought years before the dam. This is in line with the goal of an artificial flood, allowing 50,000 ha total for left & right banks in recession agriculture even with hydropower (World Bank, 2001; Acreman, 2003; Sarnak, 2003; Scudder, 2005), though 50% less than recommended over a 15 year period by GFC&C (see Section 7.8.1.1 Senegal River).

ESKOM, the South African company operating the Manantali and its hydropower stations, estimates artificial floods lasting for about 7 weeks from the third week in August to the first week in October (Tshibingu, 2006a) or 8 weeks ending in the second week in October (OMVS/IRD, 2001), in line with flooding from other tributaries, even in dry years, but not during drought periods (traditionally a couple of weeks to up to 4 months in length, [Bossard, 1999]; 5 months for an average flood, [GFCC, 1980h]). This allows a target of 50,000 ha inundated (OMVS/IRD, 2001; Maiga, 2007; Tshibingu, 2006b) for 25 (Maiga, 2007) to 25-30 days (OMVS/IRD, 2001) to be available for recession agriculture, 80% in Senegal, 15% in Mauritania and 5% in Mali (Tshibingu, 2006b) or 34% on the right bank and 66% on the left bank (OMVS/IRD, 2001). While the target is 50,000 ha, land available for recession agriculture can vary from 45,000 ha to 70,000 ha depending on the annual rainfall (OMVS/IRD, 2001). According to Maiga (2007), by August 20th of each year, the “OMVS Water Permanent Commission” must determine if there will be an artificial flood and if so the magnitude of the flood based upon Manantali’s reservoir level and the hydrology of the Senegal River at that time.

This implies a total flood of greater than 50,000 ha annually since not all areas flooded would be viable for agriculture (e.g., depending upon location of villages

to area flooded, soil quality, pasture, etc.) (OMVS/IRD, 2001), some estimating a 100,000 ha flood being required (Acreman, 2003; WEC, 2003), while GFCC (1980b; 1980d) estimate the average annual flood would still have been 190,000 ha without artificial flooding under full development including 255,000 ha under irrigation (far from being achieved), hydropower and navigation (see Footnotes, Table 7.5). GFCC (1980d) estimated that under full irrigation development by 2028, of the 190,000 ha flooded about 64,000 ha of land would still be inundated for 30 days or more/year making it available for recession (*waalo* and *falo*) agriculture of which 73% or 47,000 ha (44,500 in *waalo*) would be cultivated. This compares to the “smallest recorded flood” in 1972 of 104,000 ha as opposed to the largest recorded historical flood of 838,000 ha in 1924 (GFCC, 1980b; 1980d). Thus land currently available for recession agriculture is not too different from the GFCC scenario under full development, only that irrigated agriculture has failed to make up for the loss of traditional production systems. If one applies the formula OMVS/IRD (2001) of:

- Recession Agriculture (ha) Matam to Dagana =

$$[1.1392 \text{ Total Area Flooded (ha)}] - 34,289 + 5,890$$

derived from a data curve that assures 45,000 – 70,000 ha in ha recession agriculture four out of five years for annual floods not greater than 100,000 ha, and for areas under recession not greater than 80,000 ha [no formulas were provided for once every two years, the scenario currently chosen by OMVS (OMVS/IRD, 2001; Maiga, 2007) - though both curves are fairly close together], then the following can be determined (Figure 7.4):

- For 45,000 ha in recession agriculture a total annual flood of 64,430 ha from Dagana to Matam;
- For 50,000 ha in recession agriculture a total flood of annual 68,819 ha from Dagana to Matam; and
- For 70,000 ha in recession agriculture a total flood of annual 86,376 ha from Dagana to Matam.

In addition, based upon the analysis of satellite imagery from 1998/99, the area flooded above Matam amounted to about 19% of the area flooded between Dagana and Matam. Another 1% came from the Koundi marigot in the Middle Valley of Mauritania and Ngalenga marigot in the Lower Valley of Senegal (OMVS/IRD, 2001). This implies that the total area flooded is larger area than indicated by the above equation and that a slightly larger area than shown above (45,000, 50,000 & 70,000 ha) is available for recession agriculture. If this is the case, under the above annual flood scenarios one might expect:

- For 45,000 ha plus in recession agriculture, total area flooded in SRB Valley = $64,430 + (0.20 \times 64,430) = 77,316$ ha;
- For 50,000 ha plus in recession agriculture, total area flooded in SRB Valley = $68,819 + (0.20 \times 68,819) = 82,583$ ha; and
- For 70,000 ha plus in recession agriculture, total area flooded in SRB Valley = $86,376 + (0.20 \times 86,376) = Y$ or 103,651 ha.

Available pasture has been significantly reduced (Acreman, 2003), our analysis estimating a loss of 355,000 - 472,000 ha of pasture/year or more depending how much of the flood recession agricultural residue is made available to livestock after the harvest (see Section 7.8.9.1, Senegal River). It can easily be ascertained

due to a decline in both magnitude and duration of flooding that the freshwater fishery yield would be significantly lower than projected by the GFCC study at an average 190,000 ha total flood/year after full development versus an actual 77,000 – 104,000 ha total flood/year at 60 kg/ha annual yield/catch (4,620-6,240 tons/yr), or less due to flood durations on average of 5 months in the pre-dam era versus 7-8 weeks today that would adversely impact fish production and thus the annual yield/catch. If pre-dam fisheries averaged 46,755 tons/year (see Table 7.5) and post dam fisheries as predicted are 3,000 tons/yr from the Manantali reservoir (see Table 7.6), 4,620-6,240 tons/yr from the floodplains based upon ESKOM flood estimates, and 10,186 tons/yr from the Delta area (see Table 7.6), this would result in yields of 17,806 – 19,426 tons/yr or less; a deficit of 27,329 -28,949 tons/yr of fish (58%-62% decline). A limited flood of this duration and magnitude could also continue to adversely impact upon groundwater recharge and the quantity and area of nutrient rich sediment deposited on the floodplains.

The continuation of an artificial flood will require 1) political will and 2) specific instructions from the OMVS to the private operator (ESKOM South Africa) of the Manantali Dam, requiring the allocation of water for such purposes on an annual basis. Uncertainty remains about the will of the member states to maintain the artificial flood, a suspicion confirmed by OMVS's pursuit of the navigation component of its program, a year-round water level requiring water in excess of that required by irrigation (Adams, 2000c).

It is to be feared that, given the generally disappointing results of the agricultural development and the very shaky economic basis of the navigational sector, the riparian countries will be “forced” to reimburse the loans contracted for the building of the hydraulic infrastructure, almost entirely from the sale of electricity. This may compromise the continued support of the artificial flood, which, though officially justified only by the needs of recession agriculture, has at

least partially satisfied the more general water needs of the multi-functional floodplains (Pottinger, 1997; Hamerlynck, *et al.*, 2000).

There is a fundamental choice to be made in agricultural policy for the Senegal River Valley, between striving to make the dams generate revenue from electricity, large-scale irrigation, river transport, etc., or using them to ensure the survival of downstream family farming and related activities (e.g., flood recession agriculture, dry season forage, freshwater and estuarine fisheries). This debate has not taken place and if the debate does not take place now, the question will not be resolved once and for all, and the losers from the Manantali Dam will have lost out forever (Adams, 2000c). Ideally, there will be a need for a degree of compromise on both sides, hopefully assuring the long-term viability of natural production systems.

Senegal River Estuary, Bas Delta of Mauritania

Plans also existed to create an artificial estuary linked to the Diawling (Jawling) National Park, Mauritania. As a means of mitigating the above changes, the USAID assessment recommended constructing a 3 km long canal from Debi on the Senegal River to the Tianbrank-Diaouling Complex on the Mauritanian side of the river. The canal is upstream of the Diama Dam. By use of control gates and/or passive flooding by flow regulation from the Manantali Dam, this complex could be turned into an artificial estuary, which would in part help to offset the above losses, as well as greatly diminish the risk of species extinction. At the time, 1984, the following was concluded (DeGeorges, 1984): 1) additional studies would not improve on the ability of the decision-making process as to what mitigative actions might be necessary in this study area; 2) it was considered a worthwhile risk to continue in an operational mode to create an artificial estuary; 3) there should be no delusion that creation of an artificial estuary of 10,000-

35,000 ha might replace that which would be lost on both sides of the river, amounting to 100s of 1000s of ha of aquatic habitat; 4) it might help maintain the integrated traditional life styles of 4-5,000 persons through a combination of fishing, herding and truck farming; 5) a monitoring and surveillance program should be developed by OMVS to monitor fisheries, aquatic and terrestrial ecology as the result of an operational artificial estuary; 6) the people of the Bas Delta should be organized into independent cooperatives to aid them in improving yields from fishing, truck gardening and to improve transport of produce to the market place; 7) involvement of the *prefet* of Keur Macene and the *Direction de Pêche de Mauritanie* in the above decision-making processes was considered critical; and 8) The Bas Delta supported 842 families amounting to 4-5,000 people of which 349 families depended upon fishing as a major occupation.

At the time, the plan was to construct a dike with control gates between the dunes of Ebden and Burette, and Ebden and the coastal dune in order to close off the Bas Delta from the main estuary. Plans were to close the gates in August and use controlled flooding from the Manantali to inundate the Bas Delta from north to south via the Walalane *Marigot*. This would have been the reverse of traditional water movement off the main river northward during flooding (DeGeorges, 1984) and it was unclear how this might impact water quality and the movement of migratory fish species.

According to Hamerlynck, *et al.* (2000), the salinisation tendency of the Lower Delta, already evident with the weaker floods of the seventies, was exacerbated during and after the construction of the Diama Dam and the associated embankments, finished in 1990. With the exception of the flood of 1987 there was a very low input of fresh water into the floodplains. Eolian deposits in the channels have severely disturbed the flow patterns. Wells tapping the freshwater

lenses in the dunes have progressively become more saline in a south to north sequence.

To support this decidedly modern approach, the Mauritanian government, IUCN and its local and foreign partners started in 1994 by organising a visit of a multi-disciplinary team, composed of sociologists, hydrologists, agronomists, ichthyologists, protected area specialists, a botanist and an estuarine ecologist. In order to integrate the views of the local population, a participatory approach was favoured. It was immediately clear that local knowledge of the former functioning of the system was highly developed and that it would be indispensable for the drafting of the management plan (Hamerlynck, *et al.*, 2001). About 16,000 ha have been placed under management (Kloff, 2002).

At the start of the IUCN project in 1994, of the hydraulic infrastructure needed to restore the flooding and create the artificial estuary, and that should therefore have been in place at the Diama Dam closure in 1986, only the sluice gate at Lemer was fully operational. The implementation of the rest of the major objectives of the management plan (1997-2000) was jointly financed by the *Caisse Française de Développement*, the *Fonds Français pour l'Environnement Mondial* and IUCN. As the local fishermen had an extremely detailed knowledge of pre-dam hydrology and fish migration and spawning patterns, technical collaboration was very productive. The Berbar sluice gate was added to the original scheme in order to allow for fish migration to and from the spawning grounds in the Diawling-Tichilit Basin. The extra expense on this sluice and a second one (the Lekser sluice gate) for shrimp migration, added on the advice of the brackish water fishermen of Zire Sbeikha, prevented the project from completing the embankment that should have been delimiting the park's northern edge. Manipulation of floods allowed certain fish species, *Sporobolus spp.* and other grasses, and water birds to come back (Hammerlynck, *et al.*, 2000).

The basic scenario of artificial flooding is (Acreman, *et al.*, 2000):

- On 1 August releases are increased so that the water level rises at maximum 1 cm/day, so that the growth of grasses, such as *Sporobolus robustus* and *Echinocloa colona* can keep pace. The grass provides habitat for fish that spawn on the floodplain and for the nesting of crowned cranes.
- Annual yield/catch of fish increases with flooded area by around 100 kg/ha.
- The flooded wetlands provide habitat for many thousands of migratory birds.
- After 45 days of inundation, salt has been leached from the soils and the water is allowed to drain off, to prevent colonization by unwanted species such as *Typha* and cypergrasses.
- In the dry season, the *Sporobolus* is exploited for the production of mats, providing the main source of income for local women.
- The *Echinocloa* provides excellent grazing for the thousands of cattle visiting the delta.

Village gardening began. *Sporobolus spp.* allowed the development of a pilot project for the artisanal production of mats made of grass and leather, a specialty of the Moorish women. Concern existed that development was resulting in immigration of people to take advantage of improved fishing, pasture and agriculture, resulting in overuse of the limited resources. Concern exists that the Diawling Park may become a green fleck surrounded by agricultural land as “ecological refugees” move in from other degraded areas to take advantage of economic opportunities. This would place excessive pressure on the resource base. (Hamerlynck, *et al.*, 2001; Hamerlynck & Duvail, 2003).

The development of market gardening may also increase pressure to modify the water management system: the main market gardening season is January to March, when the park is normally progressively drying out and its waters are becoming brackish. Putting more fresh water in that season may irrevocably modify the diverse pastures of the basins into the reed-mace mono-culture observed in the Diama Reservoir. Similar claims for as much fresh water as possible for as long as possible have caused severe degradation and loss of multi-functional floodplains in the Upper Delta (Hamerlynck, *et al.*, 2001).

One might ask if what we are witnessing is an attempt to recreate a natural system whose productivity can never be replaced and whose limited size and resource base in the form of a 16,000 ha artificial estuary is too small given the current human population pressures in the area. Is this reversed development? Is this not the same phenomenon being observed in “community programs” all over Africa, where people have been compressed into areas that can no longer support them to create farms for European settlers, as well as parks and protected areas, and where these same people are encouraged to become sedentary? Combined with the 20th century population explosion, even if in a natural state, much of rural Africa can no longer support the majority of people in traditional lifestyles. This is raised over and over again throughout this book, but once again conservation on its own that does not fit into a larger development plan linked to urbanization and industrialization/high tech that can take the pressures off these rural areas and their associated subsistence lifestyles appears to fail. Africa’s fragile ecosystems are not evolving to support current human population numbers. Conservation fails even more when so-called development makes things worse instead of better! Hamerlynck and Duvail (2003) indicate that by 1998 floods reached the Southern portion of the Aftout-es-Sahel, with goals of flooding up to 50,000 ha. This is 15,000 ha above the originally planned artificial estuary maximum of 35,000 ha (DeGeorges, 1984). Research is ongoing as to the relationship between

duration of flooding and production for various resources (Hamerlynck & Duvail, 2003).

7.10.7.2 Gambia River

Major mitigative actions to most adverse impacts would be to develop the Gambia River Basin without the Balingho Barrage and ideally without the Kekreti, preferentially with a high dam in the Guinean portion of the basin. Of course, this implies that flow regulations would assure the survival of traditional production systems as described in this chapter. It appears the Sambangalou has been selected (International Water Power and Dam Construction, 2005).

7.10.7.3 Kariba and Cahora Bassa Dams, Zambezi River

The Government of Mozambique has recently declared the Marromeu Complex of the Zambezi Delta as the first “Wetland of International Importance” in Mozambique, under the Ramsar Convention on Wetlands, an international agreement for the protection and sustainable use of wetlands. The 688,000 ha Marromeu Complex includes the Marromeu Special Buffalo Reserve, four surrounding hunting concessions (*coutadas* 10, 11, 12 and 14), the Sena Sugar Estate and coastal mangroves on the south bank of the Zambezi Delta (Zambezi Valley News, 2003a) (Figure 7.5). Once again, the major mitigative activity would be controlled flooding downstream of the two dams.

“Prescribed flood releases from Cahora Bassa Dam, however, are achievable. Cahora Bassa’s 8 sluice gates are located 111 meters below the crest...and are below the average operating level of the reservoir, while Kariba’s...gates are installed near the crest of the dam and are only operated for emergency water releases when the reservoir is near capacity” (Beilfuss, 2001). “The crest height of the Cahora Bassa Dam face is 331 meters and that of the Kariba 131 meters high” (Beilfuss & dos Santos, 2001). “Beilfuss has

simulated the capacity for different flood releases from Cahora Bassa Dam using the HEC-5 reservoir routing model for the entire Zambezi catchment. Using an historical 92-year flow series accepted by the SADCC Hydroelectric Hydrological Assistance Project and *Unidade Tecnica de Implementacao de Projectos Hidroelectricos-Mozambique*, he modeled the potential to generate short-duration, high-volume flood releases of different magnitude, timing, and duration from Cahora Bassa Dam. Each flood release is analyzed in terms of its effect on hydropower generation, including firm power reliability and total energy output. The study demonstrates that a variety of options are available for generating meaningful flood pulses during the normal flood season months of January, February, or March, without a significant reduction in hydropower" (Zambezi Valley News, 2003b).

Four steps are recommended towards the creation of an artificial flood (Zambezi Valley News, 2003b):

- Applied research on environmental, social and economic implications of an artificial flood.
- Assessment of flood magnitude and duration on physical and biological processes such as sediment deposition on floodplains, the release of hypolimnion waters on fish populations, vegetative communities and wildlife.
- Analysis of socio-economic impacts of an artificial flood such as on recession agriculture, grazing and fishery production (e.g., people now settled on floodplains would need to move again and one would have to determine how to flood the Marromeu Complex without adversely impacting the Senna Sugar Estate).
- Development of an integrated plan and operational scenarios of flow releases creating an artificial flood that to various degrees maximizes benefits to all or some of the above parameters.

It is planned that these scenarios will be developed in collaboration with all stakeholders, including the Sena Sugar Estate, safari operators, government and other affected people (e.g., local communities, especially those who are living on the floodplain). Once a final operational scenario has been chosen, monitoring of controlled flooding and its impacts will take place and adjustments will be made in flow releases to maximize benefits to all stakeholders and related resources.

However, the tradeoffs mean quick money from electricity of US\$ 20 to US\$ 30 million/year or some 10% to 15% of the value of Cahora Bassa power generation (WCD, 1999). A new power system will be built at M'panda Ncua, 130 km (50 miles) downstream from Cahora Bassa (Issacman & Sneddon, 2000). The M'panda Ncua is a run-of-the river scheme dependent on the release of water from Cahora Bassa (UTIP, 2002).

Coinciding with high flows from other tributaries (e.g., Shire River), modeling of controlled releases from Cahora Bassa in February of $7 \times 10^9 \text{ m}^3$ (*i.e.* $2,894 \text{ m}^3/\text{s}$) in excess of power generation needs would create the desired flood peak of 9 000 m^3/s at Dona Ana, on the lower reaches of the river. As a result, energy production at Cahora Bassa South (power station/turbines) is reduced by about 8-11 %, with losses rising to 13-16% on completion of Cahora Bassa North (power station/turbines), while losses at M'panda Ncua are 7-9%. Hydropower sales from Cahora Bassa South are currently valued at about US\$ 200 million/year (Euros 215 million). The cost of an 8% loss in hydropower sales due to an environmental flow release would be about US\$ 16 million/year (Euros 17 million), while the benefits from increased food security and shrimp production downstream could exceed this figure (UTIP, 2002) along with improvements in biodiversity(UTIP, 2002).

“Investment in additional hydropower at Mepanda Uncua (M’panda Ncua) or Cahora Bassa North would increase the costs and reduce the likelihood of environmental flow releases in future” (UTIP, 2002).

Lessons of the past are still being obscured in the name of development. This will complicate the possibility of restoring the Lower Zambezi’s ecological systems through controlled flood releases from Cahora Bassa to restore pre-Cahora Bassa levels of floodplain fisheries and agricultural production. Despite the history of Cahora Bassa, the Mozambican government’s desire to harness economic benefits from the Zambezi, above social and ecological goals appears to be pushing towards the construction of what could be another white elephant (Isaacman & Sneddon, 2000). It is said that the World Bank supported the Mozal aluminum smelter, employing 400 people, which at peak will use 75% of Mozambique’s electricity. This smelter, owned primarily by BHP Billiton, a London-listed merger partner of Gencor (South African owned), and minority shareholder Japanese Mitsubishi Corporation (Bond, 2002), along with the new hydropower schemes will make the partitioning of water for artificial floods that much more difficult. Multi-stakeholder workshops will take place to determine how to best address the various demands for water in the Lower Zambezi (UTIP, 2002). The first such meeting took place in 2005.

7.10.7.4 Kafue Flats, Zambia

A priority must be to restore the original population size of Kafue lechwe and to reintroduce this species into areas where it no longer occurs. In the 1960s, the Worldwide Fund for Nature bought two farm estates in the central region of the Kafue Flats and established Lochinvar National Park and Blue Lagoon National Park, both declared Ramsar wetland sites. WWF-Zambia is trying to develop a partnership with ZESCO – the Zambian Electricity Supply Company – and the

Zambian government to improve water management in the flats by changing the operational rules of the Itezhitezhi Dam. WWF Zambia has started the “Integrated Water Management Project for the Kafue Flats”, in close cooperation with the Zambian government. Water experts from Zambia and the Netherlands are developing an optimal water management strategy for the flats with the principle that a healthy wetland will benefit both people and nature, with the goal of adoption by 2002 by the key stakeholders (including ZESCO, the sugar cane industry, the local communities etc.). Implementation programs should subsequently lead to a drastic change of the current water management – with its clear negative impact (WWF/Netherlands, 2002). DFID (2002) states

“that an integrated water resources management strategy should be developed for the whole of the Kafue Basin. Development must address local as well as national needs and so to be successful, local communities must be involved in the planning and management of the water and other natural resources of the Kafue Flats”.

The World Bank plans development of a road network and private lodges to turn the Kafue area into a major tourist attraction (Pavy, *pers. comm.*).

7.10.7.5 Waza Logone Floodplain, Cameroon

The opening up of the Petit Guruma water course in 1994 and the Areitekele water course in 1997 has helped to increase the flooded area by 200 km² (20,000 ha) or about 20% of the 964 km² (\approx 100,000 ha)¹⁸⁴ lost as a result of the SEMRY rice scheme and its Maga Dam. This resulted in the following benefits (Table 7.25) (Loth, 2004). This amounts to a 34 % net gain over the Euros 2,565,700 loss from the SEMRY scheme/Maga Dam.

¹⁸⁴ “The Waza Logone floodplain mostly refers only to that part of the Yaéres that are located East of the Waza Park down to the Maga dam” (Loth, 2004/8/16).

Table 7.25: Net benefits from pilot artificial flooding of Waza Logone Floodplains

ECONOMIC SECTORS	BENEFITS FROM RESTORED FLOODPLAIN INUNDATION (Euros/US\$)
Pasture Benefits	291,200/343,616
Fisheries Benefits	224,700/265,146
Agricultural Benefits	151,800/179,124
Grass Benefits	194,200/229,156
Bee Keeping	900/1,062
Surface Water Supply Benefits	8,700/10,266
NET BENEFITS	871,500/1,028,370

Source: Extracted from Loth (2004) with permission, IUCN.

These pilot schemes had a major positive impact on wildlife populations within the Waza Park, which relied on the floodplain as a dry season grazing area, demonstrating the value of artificial flooding. Major increases were observed in western kob, korrigum and roan antelope populations (Loth, 2004).

Since artificial flooding began in 1994, there has been a shift back to perennial grasses on the floodplain, especially the annual grass *Sorghum arundinaceum*, which decreased in the impact zone from 58% to 34%, while the cover of perennial grasses, most notably *Echinochloa pyramidalis* and *Oryza longistaminata* increased from 41 to 61% (Loth, 2004). This change, combined with flooding of natural waterholes on the floodplains providing water during the dry season, has resulted in an increased use of the floodplains by elephants, especially during the dry season, taking pressure off the *Acacia seyal* woodlands (de Iongh, *et al.*, 1999). However, crop raiding to the south after artificial flooding did not decrease as had been hypothesized, increasing from 10 ha in 1980 to 10,000 ha by 1998, the area raided fluctuating between 8,000 and 12,000 ha (de Iongh, *et al.*, 2004).

In addition, fishers caught 1,777 tons of fish in the additional 200 km² of flooded area during the pilot phase, while cattle numbers increased 260% without any sign of degradation to the floodplain grasslands in the pilot flood zone (Loth, 2004).

Based on the positive results from pilot artificial flooding, a number of scenarios were developed to expand flooding of the Waza Logone Floodplain without negatively impacting the SEMRY rice schemes (Table 7.26):

Table 7.26: Re-inundation options, Waza Logone Floodplain

Option	Additional Flow (m ³ /sec)	Total Flow (m ³)	% Restoration In Average Year	Total Area Reflooded Including Pilot Areas (km ²)		
				Good Year	Average Year	Poor Year
X	215	250	90	916	867	646
Y	165	200	71	839	687	532
Z	115	150	50	645	479	291

Source: Loth (2004) with permission, IUCN.

The cost/benefits from the above options were estimated to be (Table 7.27):

Table 7.27: Estimated cost and benefits for various options for artificial flooding of the Waza Logone Floodplain

Options	Physical Costs of Re-Inundation Over 5-Years		Incremental Net Benefits of Re-Inundation	
	Total (Euros/US\$)	Per km ² (Euros/US\$)	Total (Euros/US\$)	Per km ² (Euros/US\$)
X	-12,012,000/14,174,160	-3,140/3,705	2,475,000/2,920500	13,858/16,352
Y	-7,719,000/9,108,420	-3,125/3,688	1,901,000/2,243,180	11,235/13,257
Z	-3,495,000/4,124,100	-3,018/3,561	1,227,000/1,447,860	7,302/8,616

Source: Extracted from Loth (2004) with permission, IUCN.

It was recommended that Option X, based on the highest economic benefits overall and relative to costs, or Option Y, the most robust in face of risk and uncertainty of rainfall, should be implemented (Loth, 2004). Unfortunately, these

artificial floods have not been carried out on a regular basis (Funston, *pers. comm.*; *Tchamba, pers. comm.*), while wildlife must compete with cattle that move onto the floodplains, with the net result that initial gains in wildlife populations have been lost. (Funston, *pers. comm.*).

7.10.7.6 Tiga and Challawa Gorge Dams, Komadugu-Yobe River Basin, Nigeria

In the Komadugu-Yobe basin of northeastern Nigeria, there is unanimous consensus among policymakers, scientists and river basin managers that artificial flooding should play a central role in the integrated development of the river basin. As a result, wet season floods have been released from Tiga and Challawa Gorge Dams (Beilfuss, 2001).

7.10.7.7 Controlled flooding to restore floodplain production on the Pongola Floodplains, South Africa

Controlled floods from dams on the Pongola River, South Africa, provide recession irrigation, grazing and water supply to downstream users. Initial efforts to restore the downstream floodplain failed because flood releases were made at the inappropriate time of year and damaged floodplain crops (Bruwer, 1997 *In:* Beilfuss, 2001). Flood release schedules are now stipulated by the downstream community through water committees organized among 14 wards that represent the views and needs of the 70,000 inhabitants of the Pongola Floodplain (Acreman, *et al.*, 2000; Beilfuss, 2001).

7.10.8 Opposition to Large Dams

The authors believe that properly placed and with appropriate mitigation, large-scale dams (dam wall higher than 15 meters higher) have value. Unfortunately, as the case studies in this chapter demonstrate, mitigation rarely happens; corruption and big profits often get in the way of doing what is correct from a technical viewpoint. A coalition of NGOs published the following reasons why large- scale hydropower should be considered as a last resort (IRN, 2003).

7.10.8.1 A major expansion of large dams will harm sustainable development

1. Large hydro does not have the poverty reduction benefits of decentralized renewables.
2. Including large hydro in renewable (energy) initiatives would crowd out funds for new renewables.
3. Promoters of large hydro regularly underestimate costs and exaggerate benefits.
4. Large hydro will increase vulnerability to climate change.
5. There is no technology transfer benefit from large hydro.

7.10.8.2 A major expansion of large hydro will harm people and ecosystems

6. Large hydro projects have major negative social and ecological impacts.
7. Efforts to mitigate the impacts of large hydro typically fail.
8. Most large hydro developers and funders oppose measures to prevent the construction of destructive projects.
9. Large reservoirs can emit significant amounts of greenhouse gases.

7.10.8.3 A major expansion of large hydro will harm energy security

10. Large hydro is slow, lumpy, inflexible and getting more expensive.
11. Many countries are already overly dependent on hydropower.
12. Large hydro reservoirs are often rendered non-renewable by sedimentation.

The World Bank has calculated that every year some 0.5-1% of global reservoir capacity is lost to sedimentation (meaning that 240-480 new large dams would have to be completed every year just to maintain global reservoir capacity).

7.10.9 Water for life, not for death!

At the Second International Meeting of Dam Affected People and their Allies, Rasi Salai, Thailand, 28 November - 4 December 2003, the following principles and demands of the Curitiba Declaration¹⁸⁵ of 1997 reaffirmed (Rasi Salai Declaration, 2003):

- “We oppose the construction of all socially and environmentally destructive dams. We oppose the construction of any dam which has not been approved by the affected peoples after an informed and participatory decision-making process, and that does not meet community-prioritized needs.
- We demand full respect for indigenous peoples' knowledge, customary resource management and territories and their collective rights to self-determination and free, prior and informed consent in water and energy planning and decision-making.

¹⁸⁵ Affirming the Right to Life and Livelihood of People Affected by Dams, Approved at the First International Meeting of People Affected by Dams, Curitiba, Brazil, March 14, 1997
<http://www.irn.org/dayofaction/index.asp?id=background2.html>.

- Gender equity must be upheld in all water and energy policies, programs and projects.
- There must be a halt to the use of all forms of violence, intimidation and military intervention against peoples affected and threatened by dams and organizations opposing dams.
- Reparations must be made through negotiations to the millions who have suffered because of dams, including through the provision of funds, adequate land, housing and social infrastructure. Dam funders and developers and those who profit from dams should bear the cost of reparations.
- Actions, including decommissioning, must be taken to restore ecosystems and livelihoods damaged by dams and to safeguard riverine ecological diversity.
- We reject privatization of the power and water sectors. We demand democratic, accountable and effective public control and appropriate regulation of electricity and water utilities.
- Governments, funding institutions, export credit agencies and corporations must comply with the recommendations of the WCD, in particular those on public acceptance and informed consent, reparations and existing dams, ecosystems and needs and options assessments. These recommendations should be incorporated into national policies and laws and regional initiatives.
- Governments must ensure investments in research and application of just and sustainable energy technologies and water management. Governments must implement policies which discourage waste and over consumption and guarantee equitable distribution of wealth.
- The construction of interbasin transfer schemes, river inter-linking and other water megaprojects must halt.
- The international carbon market must be eliminated.
- Waterways for navigation should follow the principle ‘adapt the boat to the river, not the river to the boat.’

We commit ourselves to:

- Intensifying our struggles and campaigns against destructive dams and for reparations and river and watershed restoration.
- Working to implement worldwide sustainable and appropriate methods of water and energy management such as rainwater harvesting and community-managed renewable energy schemes.
- Continuous renewal and vitalization of diverse water knowledge and traditions through practical learning especially for our children and youth.
- Intensifying exchanges between activists and movements working on dams, water and energy, including through reciprocal visits of affected peoples from different countries.
- Strengthening our movements by joining with others struggling against the neo-liberal development model and for global social and ecological justice.
- Celebrate each year the International Day of Action Against Dams and for Rivers, Water and Life (March 14)".

Unless the West's attitude towards "development" in Sub-Saharan Africa is undertaken with the goal of really helping the subcontinent move forward instead of making a quick profit at the expense of its people and their natural resources, the authors would tend to agree with these conclusions. However, if the West's and Sub-Saharan Africa's political elite change their attitudes and want to do it right – then in a number of instances, such as a large dam properly located in the Gambia River (Sambangalou Dam), large dams could play a vital and multi-faceted role (electricity, irrigation, potable water, flood control and artificial floods to maintain traditional food producing ecosystems, navigation, etc.). Unfortunately, at this time the willingness to develop a "Hippocratic Oath" for development including dams appears to be far in the future. Transparency International (2005) goes into great detail as to why construction projects in

general are prone to corruption. This is due to the complex network of contracts between governments, donors, contractors and subcontractors and the construction industry's culture of secrecy with opportunities for cost overruns, kickbacks, using less material than specified in the contract (e.g., watering down cement, less re-enforcement steel than specified), etc. Bribery is often seen as a cost of doing business in order to be awarded a contract. Maybe taking some of the individuals, governments and dam builders to court for human rights violations could set a precedent for the development of moral and ethical values related to not only dams, but also conservation and development.

7.11 ALTERNATIVES TO LARGE DAMS

Alternatives to large dams include:

- **The improvement of traditional agricultural production systems** – dryland farming and recession agriculture, fisheries management and pasture management (Postel, 2002).
- **Alternative energy** – gas, wind, solar, small hydro (up to 10 MW), improved firewood/charcoal management/efficiency, (Postel, 2002; IRN, 2003), geothermal, tidal, wave and other marine energy (IRN 2003). One of the most prominent global initiatives is the Johannesburg Renewable Energy Coalition (JREC), launched by the European Union (EU) at the Earth Summit/World Summit on Sustainable Development (WSSD) in Johannesburg in September 2002 with 80 countries joining by 2003 (IRN, 2003). With all of the dams that have been built, “80% of Sub-Saharan Africans have no electricity. Access to basic, clean energy services – including non-electrical technologies such as biogas, improved cooking stoves and mini-hydro plants used for mechanical power – is essential for

poverty eradication. These services can also provide major health and literacy benefits" (IRN 2003).

- **Watershed management** to capture and store water (Postel, 2002).
- **Wetland protection** to moderate floods (Postel, 2002).
- **Mini-barrages** as discussed in Section 7.9.5.2, Gambia River.
- **Micro-irrigation** in gardens – In Zimbabwe, 20,000 ha is irrigated like this, 10% of all irrigation in country (Postel, 2002).
- **Efficient water use control and conservation**, which are aspects of water demand management (Bobotti, 2000).
- **Water recycling and groundwater recharging** which require the right technology (Bobotti, 2000).
- **Water storage** development and distribution for different uses, to different places of use and at the appropriate time, which require the right technology and substantial funding (Bobotti, 2000) (e.g., local rain water harvesting, underground reservoirs).
- **Enabling environment of good governance**, which makes and pursues the right policies (Bobotti, 2000).

During the decade since the Earth Summit in Rio de Janeiro, Brazil, the world's water problems have worsened markedly even as concern about them has risen steadily. Overshadowed at Rio by other pressing issues, notably climate change, biodiversity, and forests, fresh water came under a brighter spotlight during the 1990s. A steady stream of global commissions, conferences, and networks drew attention to water's fundamental importance to food production, human health, poverty alleviation, ecosystem protection, and regional peace and stability (Postel, 2002).

Actual improvements on the ground, however, have lagged badly behind this growing awareness. At the World Summit on Sustainable Development

(WSSD) in Johannesburg, South Africa, Governments and society-at-large took a new and critical opportunity to make efficient, equitable, and sustainable use of fresh water a top priority. U.N. Secretary-General Kofi Annan identified water as one of five areas (along with energy, health, agriculture, and biodiversity) (Postel, 2002).

All non-marine life depends on fresh water for survival. Even many coastal marine organisms rely on rivers that empty into the sea for nutrients and the maintenance of particular levels of salinity. Water is therefore not just a commodity, like oil or copper, but rather a fundamental life support. Rivers, lakes, wetlands and other freshwater ecosystems are not just sources of supply; they are habitat for a wide variety of plant and animal species. These ecosystems also perform valuable services for human societies such as moderating floods and droughts, purifying water, and sustaining fisheries. As a resource for human activities, fresh water is also unique in that it has no substitutes in most of its uses. It is essential for growing crops, for manufacturing material goods, and for drinking, cooking, and other household functions (Postel, 2002).

Throughout the 20th century, the principal challenge of water managers was to satisfy humanity's rising demand for irrigation, urban-industrial water supplies, flood reduction, and hydropower generation. They did this by building more and larger dams, dikes, river diversions, and groundwater wells. Just since 1950, the number of large dams (those at least 15 meters high) has climbed from 5,000 to 45,000, an average of two new large dams a day for the last half century (Postel, 2002).

This combination of rising demand and ecosystem alteration has depleted supplies, damaged ecosystems, and placed a large share of freshwater life at

risk of extinction. Water tables are falling from the over-pumping of groundwater in large portions of China, India, Iran, Mexico, the Middle East, North Africa, Saudi Arabia, and the United States. Many major rivers including the Colorado, Ganges, Indus, Rio Grande, and Yellow now run dry for portions of the year (Postel, 2002).

Freshwater wetlands have shrunk by about half worldwide. Moreover, increasingly, competition for water threatens social and political stability both within and between countries. In recent years, violent protests have erupted in the lower reaches of China's Yellow River and Pakistan's Indus River as farmers faced the prospect of a cropping season without sufficient irrigation water (Postel, 2002).

A fundamentally new approach to water and human development will be needed during this new century an approach that aims to satisfy the water needs of 8-10 billion people while protecting the ecosystems that sustain our economies and all terrestrial life (Postel, 2002).

7.12 CONCLUSION

It can be argued that by the time dam construction really took off, there should have been enough knowledge by Western dam builders, who moved into Sub-Saharan Africa, to understand the environmental and social consequences of placing dams on rivers and what mitigative actions would be needed. Even if this was not the case, the detailed analyses on the Senegal and Gambia Rivers laid open the suppurating wounds that would occur if mitigation was not undertaken. In both studies, multi-disciplinary teams of hydrologists, modellers, engineers, public health doctors, wildlife and fishery biologists, agronomists and anthropologists/sociologists were employed. The consequences of building these

dams were literally examined under a microscope. The studies fill volumes of reports, not available to the general public – at least not easily available. Hydrological modelling was undertaken; gains and losses of traditional versus irrigated food sources were estimated. Plans existed for artificial floods as a major source of mitigation downstream. In this chapter, with few exceptions, regardless of the dam, one can see similar consequences.

In the case of the Senegal River, a little “white lie” was told that yes, traditional food sources would be lost, but that people should not worry as this would be made up with irrigation. All the while, major constraints to irrigation, while maybe not buried, were certainly not sufficiently highlighted, such as saline groundwater, soil salinization, diseases and the cost/ha of irrigation. Nutritional projections showed irrigation more than making up for the losses of traditional foodstuffs. The environmental assessment was purposely flawed, in the hopes that by justifying these dams there would be more follow-up work. This paved the way for the construction of two dams on the Senegal, the displacement of 10-11,000 people behind the dam, adverse impacts on traditional production systems used by between 500-800,000 people below the dam, conflicts between traditional herders and farmers and the near eruption of a war between Mauritania and Senegal. Most of the people displaced by the dams today are worse off than before due to having both poorer quality and less land and for many there is substantial psychological trauma due to loss of their ancestral lands and the spiritual ties that go with them. Artificial floods in the Senegal River have been inadequate to significantly impact the traditional floodplain production systems and thus the majority of people displaced downstream. With hydropower coming on line, there is concern that the artificial floods will be less, not more and maybe not at all. The rate of land going under irrigation is well behind that which was planned due to financial and technical constraints.

In the case of the Gambia River, after a joint member state/USA team of technicians questioned the prudence of an anti-salinity barrage due to the human and ecological tragedy that might occur, as well as the sighting of a high dam in a World Heritage Site lying along a major fault line, USAID and local politicians brought in a “prostitute consulting firm” to throw the environmental study into disrepute, justifying the politically preferred scenario over what most technicians believed made sense: a high dam located in the Fouta Djallon Mountains of Guinea-Conakry. Senegal did not wish Guinea-Conakry to control its water and wanted the anti-salinity barrage for easy access to the unruly secessionist movement in the Casamance, and well if there was a “*chicken in every pot*”, a dam in each country, maybe plenty of kickbacks for the political elite from the international construction companies. As usual, politics and big bucks overrode common sense, and only behind the scene threats by an environmental legal group to take the U.S. Government to court stopped this action. The high commissioner knew that the Balingho Anti-Salinity Barrage would be a catastrophe. Eight years earlier, when he interviewed the principal author in Washington, D.C. for the position of environmental advisor to the OMVG, he asked what could be done if the fisheries were wiped out as a result of the Balingho Anti-Salinity Barrage. The principal author responded that fish culture was one option, but never to think that this could replace the loss of a dynamic natural fishery. The fact is that Mr. John just did not care at all about the anti-salinity barrage and its impact on thousands of artisanal fishermen or the 43,000 women whose rice fields would be flooded by the barrage or for that matter anything else. There appears to be little morality in dam building and this experience in addition to what the authors could glean from the literature is fairly typical.

Mitigation and planning are not the real issues. Millions have been spent on such studies. The problem is that information generated by these studies by mostly honest technicians has been misused for monetary and political gain, or just plain

ignored. The attitude of the construction firms and donors is, “We don’t live here so if it doesn’t work it’s not our problem; it will be someone else’s”. In fact, many donors moved their staff every two years to avoid having them become too integrated into the local society and too sympathetic to the local people’s needs as opposed to the political needs of the Western donors, which have been anything but long-term, especially during the Cold War when many of these dams were built.

Will things be different in the future? Based on the scandals coming out of the dams just finished, under construction or planned in Lesotho, it appears not (IRN, 2000a; Bond, 2002; Hanlon & Pettifor, 2002; Lekhetho, 2005; Transparency International, 2005). Groups such as the International Rivers Network (IRN), a watchdog group, and previously the World Commission on Dams (WCD) at one time housed in the United Nations Environmental Program (UNEP) in Nairobi, Kenya – but no longer operational, need to continue their vigilance and let the world know where dams are both constructive and destructive. On the positive side, pilot artificial flood programs in the Lake Chad Basin (Loth, 2004) of Cameroon, on the Kafue River, Zambia (DFID, 2002; WWF/Netherlands, 2002), the Zambezi Delta, Mozambique (Beilfuss, 2001; UTIP, 2002; Zambezi Valley News, 2003b), and associated with the Pongolapoort Dam on the Phongolo River, South Africa (Acreman, *et al.*, 2000; Beilfuss, 2001), offer great hope that while bringing on new technologies, the importance of maintaining traditional production systems on floodplains is being recognized in order to maintain both the people and biodiversity of Sub-Saharan Africa. In this light, it is hoped that the Senegal River Basin will become a success story for the sake of its people and their biodiversity.

If the Western donors expect to see anything but anarchy on the African continent, which risks to come back to bite them from behind in the form of

uncontrolled immigration and terrorism in revenge for what many would consider a form of terrorism, destroying the lives of millions of people on the African continent in the name of conservation and development, then they had better start making sure that the results are beneficial to the majority and not the few, in this case the people living off the land and who are directly impacted by dams. Today the majority of local people are worse off than before “development”. Consideration should be given to placing Western donors and dam construction companies on trial for human rights atrocities, but then it appears that despots from the developing world and from behind the former Iron Curtain are easily sent before the tribunal, while the West appears to have some kind of immunity from judging itself. In a modern society within the global age of communications, let us hope that humankind will no longer tolerate short-term gains resulting in long-term disasters. Then again, the authors are a bit idealistic.

Chapter 8

8.0 MINING TROPICAL COASTAL ZONES, LESSONS FROM THE CARIBBEAN, IMPLICATIONS FOR EAST AFRICAN CORAL REEFS

“For no ecosystem is the impending catastrophe more imminent than for coral reefs, the source of most of the biodiversity, fisheries, sand, tourism, and coastal protection for over a hundred countries. No other habitat on earth is more sensitive to infinitesimal increases in global temperature, nutrients from sewage and fertilizers, agricultural and industrial chemicals, soil eroded from land following deforestation and unsustainable land use, and from raging epidemics of new emerging diseases” (Goreau, 2002).

This chapter emphasizes the principal author’s experience in dealing with land-based pollution, but also highlights other factors jeopardizing coral reefs. Land-based pollution can be pinpointed and dealt with using modern technologies such as soil conservation and appropriate sewage treatment and disposal. This chapter goes into great detail in trying to sensitize the reader to the sources of this pollution, its impact on coral reefs and other nearshore ecosystems, and how to deal with this problem.

The causes of global coral reef degradation are discussed and related to the East African Coast, where the majority of Sub-Saharan Africa’s colonial “hermatypic” coral reefs are found. Special emphasis is placed on lessons to be learned from the Caribbean region, especially as it relates to appropriate sewage (brown and gray water) technology believed to be a major cause of reef degradation from nutrient pollution.

The Caribbean islands are microcosms of what is happening on the continents of planet earth, many being over-populated with natural systems mostly converted to agriculture, which is often practiced on steep slopes, and the nearshore waters acting as trash receptacles for the wastes created by humans on the land (urban and industrial sewage, sediment, pesticides, fertilizers, solid wastes, etc.). Analyzing these islands, in essence is like shrinking the African continent and placing it under a microscope, allowing one to see the big picture of what is going right and wrong with development. The advantage East Africa has over the Caribbean islands is that much of its coastal zone is relatively undeveloped with low human populations, and thus in a semi-virgin state, which is where the Caribbean was back in the 1960s and early 1970s. Thus, East Africa has the potential to learn from the mistakes of others and choose a path of appropriate development that will provide long-term economic returns for the region, while protecting the unique biodiversity of its coral reefs, associated grass beds and mangrove swamps.

8.1 INTRODUCTION

This chapter is mainly concerned with the East Coast of Africa, where colonial “hermatypic” coral reefs are found, from the Red Sea off Egypt to Sodwana Bay off South Africa, the furthest south that colonial coral reefs are found in the western Indian Ocean (East Africa and south-western Indian Ocean). On the West Coast of Africa, little or no colonial coral reef is found due to nutrient rich cold-water upwellings caused by currents linked to strong offshore winds such as the Harmatans. Here one finds rocky outcrops along the coast, rich in fish life, covered by non-colonial “ahermatypic” corals that thrive in these nutrient rich conditions.

In reality, this chapter applies to all tropical areas of the world where coral reefs are found and where development on the land from tourism, urbanization, industry and agriculture jeopardizes these unique ecosystems. In many cases, what is happening is out of ignorance, but in some cases, it is out of greed. One hundred years ago, the earth's coral reefs and associated fish populations were healthy. This is not the case at the beginning of the 21st century (Wilkinson, 2004).

Coastal tourism, as currently being undertaken in much of the tropics, is not sustainable. The number of international tourists worldwide grew from 170 to 635 million between 1971 and 1998, while the amount spent by the tourists soared from US\$ 21 billion to US\$ 439 billion. By 2020, the World Tourism Organisation predicts, 1.5 billion international tourists will spend US\$ 2 trillion a year – over US\$ 5 billion/day. However, as is discussed in this chapter, sewage, solid waste, habitat destruction, poorly placed hotels too close to beach fronts, highly fertilized golf courses next to the sea, artificially created harbors, breakwaters and jetties, a demand for seafood beyond the sustainable capacity of the area (GESAMP, 2001), boat anchors and uncontrolled SCUBA diving, etc. can adversely impact coral reefs and related habitat.

For many reasons, African coral reefs and coral reefs across the tropical world are in jeopardy, as much as if not more than the world's tropical forests. However, because the average person will never dive and see these "underwater forests" and their associated "wildlife" and because few people have a historical reference point of seeing virgin reef being "raped" by development, there does not seem to be a great sense of urgency felt by the international conservation community over the plight of the world's reefs. However, in the last few years there does appear to be a heightened awareness.

For the moment, East Africa is fortunate with regards to its coral reefs. Other than in a few highly developed areas such as Sharm el Sheikh, Mombassa, Dar es Salaam, Pemba, Maputo, etc. the coasts are relatively virgin. If greed can be controlled, there is enough knowledge, as with dams (see Chapter 7) to allow development to unfold without destroying these reefs and/or to identify key reef areas in need of protection and limit development in their watersheds so that they and their unique biodiversity may be conserved for humankind, especially for the coastal people who gain their livelihoods from the sea. It is hoped that this chapter adds to the knowledge necessary to achieve these goals.

The latest United Nations Environmental Program (UNEP) global estimate for the area currently covered by coral reefs worldwide is 284,300 km² (109,768 mi²). The atlas identifies 80 countries and/or geographical regions where coral reefs may be found - the greatest concentration is to be found around Indonesia, closely followed by Australia. In general terms, Africa is identified as hosting around 7.5% of the overall total (Spalding, Ravilious & Green, 2001), amounting to approximately 21,323 km² (8,232 mi²) of coral reefs out of the global total. Contributing to this total from other parts of the world are the Asia/Pacific (77.5% of global total), Europe (7.1%), Latin America and Caribbean (5.4%) and North America (2.5%) (Spalding, *et al.*, 2001). Leakey and Lewin (1995) argue that

“in the oceans, reef communities have been transformed periodically, as existing organisms were wiped out, coinciding in 4 cases with the major extinction crises (see Chapter 1). After each devastation, reefs reappeared, sometimes calcareous algae dominating, sometimes bryozoans, sometimes mollusks and sometimes corals. The coral reefs with which we are familiar are simply the temporary inhabitants of that adaptive zone”.

This chapter shows that as forests on land, coral reefs are being rapidly forced into extinction and converted to less biologically diverse algal reefs “at the hand of humans”. The question is, how serious is this and are humans, both in the sea

and on land, major players in the ‘6th extinction’ (see Chapter 1, Section 1.3.2, Man and the Extinction of Pleistocene Mega-fauna)?

The principal author has been diving and exploring the underwater world for over 40 years. His introduction to the underwater world began at a very young age. By 1963, when the principal author began diving, the Aqualung or SCUBA (Self-Contained Underwater Breathing Apparatus), developed by Emile Gagnon and popularized by Jacques Cousteau, was about 20 years old. The principal author made his first dive on tropical coral reefs in 1968 off Big Pine Key, Florida.

The coral reefs were virgin and the keys still relatively undeveloped in the late 1960s. After completing a M.S. that among other things looked at sport fishing on artificial reefs, as a Peace Corps volunteer from 1973-75 and then with the USEPA¹⁸⁶ in Louisiana from 1975-1977, the principal author dived at Tulum, in the Yucatan of Mexico, at Ambergris Cay, Belize – the second largest barrier reef in the world after the Great Barrier Reef of Australia, at Cayos Zapatios, Guatemala, at Roatan Island off Honduras (Figure 8.1), at the *Isla del Maize*, Nicaragua, and off Grand Cayman Island. These reefs were virgin, being found along the undeveloped coasts and fishing villages of Central America with low human populations, and all at the time had healthy coral ecosystems. When the principal author dived Grand Cayman Island in 1977, “build-out” development was just beginning as this peaceful island was being turned into one big condominium complex, and people were talking of pollution from sewage already affecting underwater visibility. There was talk of deep well injection of sewage. During this period, from 1969-1977, an underwater photographic archive was developed of what the principal author observed. The principal author then moved onto the African continent from 1977-1987 where he dived extensively off the coast of Senegal, West Africa, mainly off Dakar’s Cape Verte Peninsula.

¹⁸⁶ U.S. Environmental Protection Agency (USEPA), EMSL (Environmental Support Laboratory)/Las Vegas Baton Rouge, Louisiana

From 1988 through 1989, the principal author served as a regional environmental advisor to USAID in the Caribbean, covering all major islands on which the U.S. government had development activities plus British Honduras/Belize and Guyana. The environmental movement had caught on worldwide, and this seemed an ideal opportunity to get involved in the establishment of marine parks off the islands of the Caribbean and to continue developing an underwater photographic archive.

The principal author was based out of Bridgetown, Barbados, one of the most developed islands in the Caribbean, with an economy based on sugarcane, rum and tourism, and suffering from major coral reef degradation. One of the principal author's first assignments was to assess a wastewater treatment plant being designed by the U.S. government on the island of Grenada. Grenada had recently been invaded to save the island and the western hemisphere from communism. Grenada was a small place where they produced bananas, sugarcane and made a drink called *Ron Avec Bois Bande*, containing the bark or root of bushes (*Roupale montana* and *Chione spp.*), that acts as an aphrodisiac with potential pharmaceutical value (Johnson, DeGeorges, Jackson, Talbot & Teytaud, 1988).

As America's environmental movement had begun in the early 1970s due to rivers and streams being polluted with human and industrial wastes, the principal author had some experience in this field, having worked from 1975-1982 for an environmental engineering firm with contracts to conduct sewage treatment environmental impact statements in Region IV (southeastern USA) of the USEPA (U.S. Environmental Protection Agency)¹⁸⁷.

Because of his long-term diving experience, by then about 25 years, he had a historical reference point as to what healthy coral looked like, something very few people had or thought about at the time. In fact, he had never seen degraded coral

¹⁸⁷ USEPA Region 4, Sam Nunn Atlanta Federal Center, 61 Forsyth Street, SW, Atlanta, Georgia 30303-3104, www.epa.gov/region4

reef, since prior to 1988 it had been virtually non-existent in the areas he had dived. What he was about to encounter was a shock! The chosen site for the treatment plant was Grande Anse Beach, a beautiful half-moon bay, whose watershed contained among others a Holiday Inn Hotel - an American icon - and a medical school attended by many Americans who could not get into a U.S. school. “Clint Eastwood” rescued the medical students from the communist rebels in a 1986 movie *Heartbreak Ridge* made about the invasion of Grenada by the U.S. Military in the early 1980s to save the western hemisphere from communism. As a result, the U.S. was probably politically indebted to Grenada from this invasion over its sovereignty (DeGeorges, 1989a).

People were complaining of eye, ear and skin infections from swimming in the water along Grand Anse. Most building structures within the watershed were on septic tanks, good at eliminating organic material but not very effective at eliminating nutrients or viruses.

On arriving, the principal author walked out onto the beach expecting to see signs of organic pollution from malfunctioning septic tanks. However, the water was clear and blue, as one would expect of most tropical waters. There were no obvious signs of organic pollution, oxygen depleted, discolored and smelly water or maybe even some dead fish. Swimming out from shore, he came upon the coral reef that was virtually invisible, smothered in epiphytic algae (benthic) – mostly dead reef (Figure 8.2).

This appeared to be a case of nutrient pollution, which allowed algae to out compete the corals for space. The existing treatment systems were adequate enough to eliminate organic matter, but the nutrients were either leaching in through the groundwater in the case of the septic systems and/or being discharged directly.

Ecologically, the discharge of nutrients into the bay was resulting in the coral die-off, which the principal author had observed. Linked to nutrient pollution was an epiphytic algae that like a blanket was smothering the corals, causing the corals' death. The net result was the collapse of an entire ecosystem: the fishes' habitat! The principal author had no quantitative water quality data to backup his hypotheses. It was also obvious that both the existing systems and the planned secondary treatment plant by the U.S. government with a short outfall would be inadequate to deal with both environmental and public health issues.

Upon returning to his office in Barbados, a fax (pre-email days) was sent to his supervisor¹⁸⁸ in Washington, D.C. who was responsible for environmental issues in the Caribbean and Latin America. The fax stated that the US\$ 100,000 spent on designing the treatment plant was wasted and that less treatment, not more treatment, was needed. Money would have to be invested in minimal "preliminary" treatment and a long outfall to get the discharged effluent as far away as possible from the ecologically sensitive systems (e.g., corals and grass beds), letting the dilutional capacity of the open sea bring the discharged effluent to safe background levels. His supervisor's initial reaction was disbelief that less not more treatment was needed; he started questioning if he had hired the right person for the job. USAID and many donors often expect consultants to justify their plans, not call them into question. One of the problems with foreign aid and "development" is that employees advance within the system for justifying the expenditure of money, not doing what is right.

Fortunately, in Barbados, the principal author worked with a civil engineer who was responsible for the Grand Anse sewage works¹⁸⁹ and who was open to discussion. The principal author was also able to identify Dr. Wayne Hunte of Bellairs Research Laboratory in Holetown, Barbados, associated with McGill

¹⁸⁸ Jim Hester

¹⁸⁹ Jim Baird

University of Canada and the University of the West Indies. Dr. Hunte, a Bajan (from Barbados), had been undertaking water quality analyses both in Barbados, which had also suffered major reef damage from sewage (e.g., all fringing reef gone, major problems with beach erosion), and Grenada, among others. He was one of the few scientists at the time who understood the problem.¹⁹⁰

At a meeting, the principal author's observations were discussed. Dr. Hunte backed the principal author's conclusions and had water quality data to support them. In collaboration with Bellairs, the civil engineer redesigned the project, putting an emphasis on oceanographic studies and modeling the dilution to background levels of preliminarily treated sewage based on a long ocean outfall. The principal author never saw the final outcome of construction.¹⁹¹

Nevertheless, over the next two years, the principal author dived at most of the major islands in the Caribbean and at Belize. The principal author undertook surveys of pesticides and fertilizer use on the islands and investigated existing and planned marine parks. The following summarizes his experiences in the Caribbean and how they relate to the Indian Ocean along the eastern side of the African continent in the development of coastal tourism. Personal observations on coral reef health in both the Caribbean and the African East Coast are provided. General conclusions drawn are:

¹⁹⁰Dr. Terry Done, of the Australian Institute of Marine Science (AIMS) was another person the author met in the early 1990s at a marine symposium in Mombassa, Kenya, who seemed to share a similar understanding. The author approached scientists from the Smithsonian Institute in the 1980s but they were unaware of what was going on, as they were focused on very narrow research topics.

¹⁹¹In Table 8.7, the Point Salines Outfall appears to be the system that he worked on, demonstrating that USAID brought this process to conclusion.

- Land-based pollution is a primary cause of coral reef degradation. At the September 1988 Regional Seas Conference sponsored by UNEP in Mexico City, land-based pollution was considered the number one environmental problem affecting the Caribbean Basin;
- This is primarily from nutrient enrichment of nearshore marine waters associated with improperly or untreated domestic sewage and gray water originating from major urban areas and from tourism developments;
- The world's tropical waters are nutrient poor and ecologically thrown out of balance by this enrichment, resulting in coral reef ecosystems collapsing as a result of being smothered by epiphytic algae (benthic macro-algae), which prevents zooxanthellae (a symbiotic algae living within the coral polyp providing the coral with food and giving it color) from photosynthesizing, and the polyps from filtering micro-organisms out of the water – thus cutting off the coral's food supply and starving it to death;
- Believed to be secondary in importance in causing coastal degradation are pollutants associated with agricultural runoff including sediment, pesticides and fertilizers, often from ill-conceived donor policies (e.g., subsidized bananas in the Caribbean);
- The loss of coral reef sets off a cycle of beach erosion as the source of sand, corals, is dead (corals breaking down gradually over time provide a major source of sand along with coralline algae), and because of lost protection from wave and storm action by the collapsing reef. This along with declining artisanal fisheries from habitat loss and eye, ear and skin infections by swimmers has the net result of diminishing tourism attractions;
- Western waste treatment technologies solve neither ecological (e.g., up to secondary treatment removes primarily biological oxygen

demand/BOD but few nutrients) nor public health needs (e.g., secondary treatment as commonly used);

- High tech tertiary treatment that removes significant amounts of nutrients suffers along with secondary treatment from high operation and maintenance levels (cost of maintenance, availability of spare parts, qualified technicians, who are even hard to find in the developed world) and as a result is rarely operated up to design capacity;
- One viral particle can make a person sick. Normally, sewer water dumped at sea should not come in contact with a person for at least two days; this period of time allows for die-off from ultraviolet radiation;
- Land-based discharge of sewage requires secondary treatment and viral aerosols are still an issue (e.g., spray irrigation of golf courses), which is maintained with difficulty in developing countries. On islands, land (e.g., overland flow, crops) is a major constraint as land availability can be an issue, while during the rainy season major holding ponds are needed;
- Solutions such as long outfalls with preliminary treatment, possibly land-based treatment and deep (not shallow) well injection, exist but are ignored by governments and developers, mostly out of ignorance, in favor of simple septic systems and secondary treatment package plants with short outfalls. A recent report by Sealy (2002) of the Caribbean Water and Wastewater Association (CWWA) confirms this to still be the case;
- Once degraded, due to its slow growth rate, the coral reef system could take 100s if not 1,000s of years to come back, even if the source of pollution is removed and transplants of healthy coral are put into place;

- Most marine parks fail to deal with the major issue of land-based pollution and unless situated in a pristine watershed continue to degrade;
- Local artisanal fishermen are victims of degraded coral habitat by developers rather than the cause of the problem due to engaging in over-fishing and/or destructive fishing methods. While there is an increased need to work with artisanal fishermen to sustainably manage their fishery (e.g., breaking up the coastline/reef into fisher community-managed zones), they are not the major problem, which is coastal tourism as currently undertaken and land-based pollution in general;
- As in African parks and safari hunting areas with traditional hunters and pastoralists, hotel owners and dive operators often come into conflict with local fishermen, trying to stop access to areas that their families have fished for 100s of years in favor of exclusive high-paying clientele – SCUBA divers. This is analogous to wealthy tourists visiting Africa's parks and hunting blocks, while the local community is excluded from the lands of their ancestors;
- Coastal tourism in the tropics negatively impacts local cultures, often turning the sons and daughters of fishermen into drug dealers, gigolos and prostitutes from the immoral Western values imported by tourists;¹⁹²
- Most governments and NGOs fail to recognize the problem of land-based pollution, assuming that marine biodiversity can be protected by declaring an area a park, by putting up marker and mooring buoys, banning fishing and educating sport divers not to touch the corals. The

¹⁹² This is readily observable in many of the coastal tourism areas of Sub-Saharan Africa. Major steps are being taken by the Kenyan government and tourism industry to stop the sale of children or children selling themselves to tourists for sex in Kenya's coastal resorts (Majtenyi, 2005), a reflection of the extreme level of poverty that exists in the area and across the subcontinent.

problem is orders of magnitude more complex than this, but this simplified approach brings in lots of money to the NGOs from donors and from publicity directed at an ignorant, uninformed public contributing to the wrong cause;

- Other issues include damage by divers (education critical) and boat anchors (permanent moorings, or the dive boat floating with the divers' bubbles or a diver-towed buoy can solve this), dredging to create harbors, opening lagoons as harbors, filling in salt ponds/lagoons for housing developments, elimination of unsightly mangroves, unregulated harvest of coral and sea life for the aquarium trade, location of tourist lodges and lights too close to the beach affecting turtle nesting and sex ratios (the closer the eggs are laid to the waterline, the lower the temperatures and the more males are among hatchlings), as well as survival of the hatchlings (driven by lights from tourist hotels inland to their death); and
- Global issues such as planetary and ocean warming, the breakdown in the ozone layer, etc. have become increasingly important since the late 1990s in determining coral reef health, but often detract from people actually doing something about issues that they can physically address – these issues have to be dealt with at a global level by states such as through the Kyoto Protocol to the United Nations Framework Convention On Climate Change that addresses the burning of fossil fuels and resulting greenhouse gas (GHG) emissions. There are still major debates about long-term climate changes and to what degree they have been accelerated by humans as opposed to being part of a natural cycle. However, one thing is apparent: recent but temporary increases in ocean temperatures have resulted in major coral die-off and degradation.

Ultimately, the tropical coastal zones' long-term economic potential is auctioned off for short-term gains, mostly out of ignorance. If a proper understanding existed by temperate climate developers and tropical governments, the cost of doing it right is likely the same as doing it wrong, especially if developers and governments pooled their resources. However, rectifying the problem once it is recognized can be more expensive. The following sums up fairly well what the principal author has observed over the last 40 years of diving.

"The coral reef crisis is almost certainly the result of complex and synergistic interactions among local-scale human-imposed stresses and global-scale climatic stresses. Both can produce direct and indirect chronic (long-term events such as land-based pollution and now ocean warming), and acute (short-term events that cause rapid damage on a reef such as storms and dredging, short-term but significant increases in water temperatures) stresses, leaving few, if any, parts of the ocean truly hospitable for healthy coral reef communities. Documented human stresses include increased nutrient and sediment loading, direct destruction, coastal habitat modification, contamination, and the very important chronic indirect effects of over-fishing. The major climate change factor that is becoming increasingly important for coral reefs is rising ocean temperatures, which have been implicated in chronic stress and disease epidemics, as well as in the occurrence of mass coral bleaching episodes. Also of concern are the effects of increasing atmospheric carbon dioxide (CO_2) on ocean chemistry, which can inhibit calcification—the deposition of the calcium carbonate minerals that are the structural building materials of coral reefs. Coral reef communities usually recover from acute physical damage or coral mortality if chronic environmental stresses (such as reduced water quality) are weak, and if the acute stresses are not strong or overly frequent. Coral reefs also withstand chronic stresses in the absence of acute stresses. The combination of acute and chronic stress, however, often results in the replacement of the coral reef community by seaweeds or some other non-reef system...Whereas remote oceanic reefs will be affected primarily by climate change, reefs close to human populations will continue to be affected by combinations of additional stresses (e.g., reduced water quality, physical damage, and over harvesting) that must be considered together to be understood and managed" (Buddemeier, Kleypas & Aronson, 2004).

A good example of the problems facing coral reefs is provided in the following set of photos taken over time by the US Geological Survey on one coral head from the Florida Keys (Figure 8.3).

8.2 GENERAL

Coral reefs, associated sea grass and mangrove habitats are among the most diverse and valuable ecosystems on earth. These reef systems are storehouses of biological diversity, providing economic and environmental services to millions of people from shoreline protection, food, economic revenue from fishing, recreation, tourism and pharmaceuticals. Coral reef organisms have evolved over the past 40-55 million years with present-day reefs having accumulated during the last 5,000 (Ecological Society of America, 2000) to 10,000 years (Buddemeier, *et al.*, 2004) of the current interglacial period (the Holocene epoch). Coral reefs are one of the oldest continuous environments on earth (Ecological Society of America, 2000). “The modern reef community is the living veneer over these limestone accumulations that may be tens of meters thick” (Buddemeier, *et al.*, 2004).

The net primary productivity of coral reefs is approximately 2,500 grams of carbon/m²/year, compared to 2,200 grams of carbon/m²/year for tropical forests and only 125 grams of carbon/m²/year in the open ocean (WRI, 2002).

According to one estimate, these “rainforests of the sea” may provide goods and services valued from a high of US\$ 375 billion each year (U.S. Coral Reef Task Force, 2000; Costanza, d’Arge, de Groot, Farbar, Grasso, Hannon, Limburg, Naeem, O’Neill, Parner, Raskin, Sutton & van den Belt, 1997 *In:* Evans, 2002; Wilkinson, 2002) to a low of US\$ 30 billion (Buddemeier, *et al.*, 2004) – an

amazing figure for an ecosystem that covers less than 1% of the earth's surface (U.S. Coral Reef Task Force, 2000; Costanza, *et al.*, 1997 *In:* Evans, 2002). Approximately 500 million people in tropical countries have some dependence on coral reefs (Wilkinson, 2002). The reefs of Florida are valued at US\$ 1.6 billion per year from tourism, while the Great Barrier Reef in Queensland is valued at US\$ 1.5 billion. No such analyses exist for the Indian Ocean/East Africa (CORDIO, 1999).

8.2.1 Distribution of Coral Reefs

Colonial coral reefs are found within a 7,770 km (3,000 mi) wide belt bounded by the Tropics of Cancer and Capricorn, respectively 23.5° north and south of the equator.

8.2.2 Biodiversity of Coral Reefs

Reef-building (or hermatypic) corals are of the order Scleractinia in the class Anthozoa of the phylum Cnidaria. Approximately 6,000 species of Anthozoans exist, all of them marine (Turner, 2002). Reefs support more species per unit area than any other marine ecosystem, including about 4,000 documented species of fish, 800 species of hard corals and 100s of other species. Scientists estimate that there may be another 1 to 8 million undiscovered coral reef species. In many ways, coral reefs rival and surpass tropical rainforests in their biological diversity and complexity (Pomerance, 1999; Evans, 2002). These tropical marine communities occupy less than 1% of the ocean floor, but represent some of the most biologically diverse ecosystems on earth, providing critical habitat to approximately 25% of marine species (Ecological Society of America, 2000; Buddemeier, *et al.*, 2004) from 32 of the world's 33 animal phyla live – four times the number of animal phyla found in tropical rain forests.

This biodiversity may be a source of natural products derived from reef dwelling organisms. Many pharmaceuticals are now under development from coral reef animals and plants as possible cures for cancer, arthritis, human bacterial infections, viruses and other diseases. Coral reef ecosystems are considered a key source of natural compounds for new medicines for the 21st century (Pomerance, 1999; Evans, 2002).

The two major centers of hermatypic coral reefs are the Indo-Pacific and the Atlantic. The heart of coral reef biodiversity is in Southeast Asia in what is known as the "coral triangle". The Indo-Pacific supports 85% of the world's coral reefs and a similar level of biodiversity (Veron, 1995 *In:* Buddemeier, *et al.*, 2004). This center of biodiversity is found on the world map by drawing a triangle encompassing New Guinea, the southern tip of Sumatra and the Philippines. This area alone contains more than 500 species of reef building corals, compared to only 60 to 70 species found in the Caribbean (Coral Reef Alliance, 2002a). Buddemeier, *et al.* (2004) estimate that the Indo-Pacific, which includes Southeast Asia, has 750 species of reef building corals.

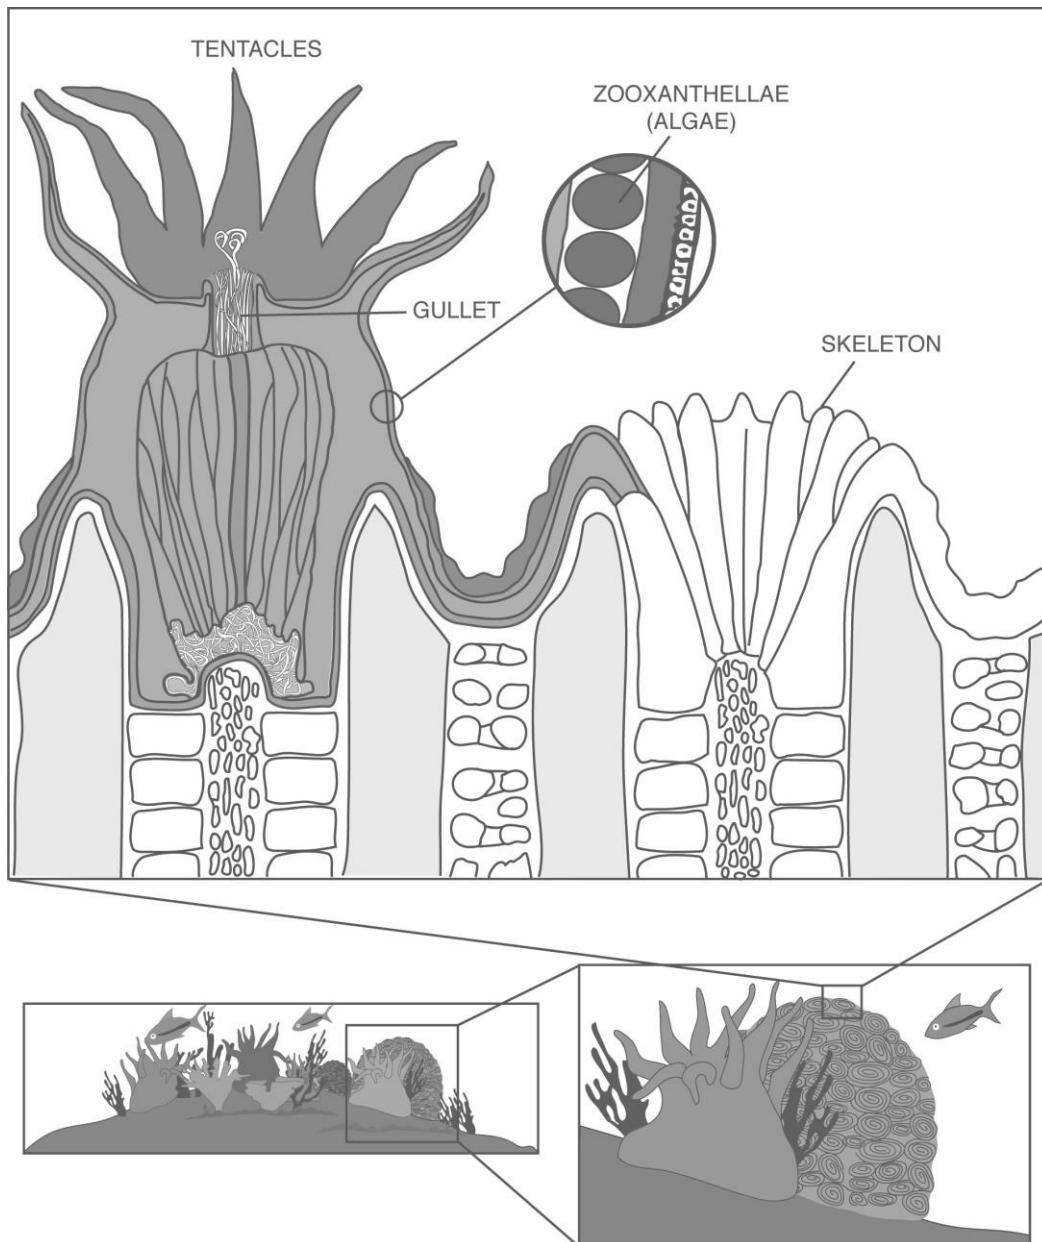

8.2.3 The Dependency of Coral Reef Communities on Other Aquatic Ecosystems

The survival of coral reef communities is strongly tied to a number of aquatic ecosystems and their environmental health. These ecosystems include sea grasses, mangroves and salt ponds (DeGeorges, 1990a). It is estimated that 50% of the world's mangroves have been lost over the last century due to actions by humans (GESAMP, 2001). Coral reefs cannot be seen to exist in isolation of other marine ecosystems. The protection of coral reef communities will require not only a systems approach, but will require a watershed approach if they are to have

a future. “We cannot interfere in one area of the ecosystem without paying due attention in other areas and to the well being of future generations” (John Paul II, 1989 *In:* DeGeorges, 1990a). A study on four barrier atolls on the Belize Barrier Reef found that with the exception of the rainbow parrotfish (*Scarus guacamaia*), most reef fish have no functional dependency on mangrove nurseries, though mangroves can strongly influence the community structure of fish, directly or indirectly. Species of haemulids (e.g., grunts, porkfish), snappers and parrotfish benefited from the extent of nearby mangroves; the standing stock of fishes using mangrove nurseries being considerably greater when there is a reef close to the mangroves. Seagrasses also serve as nursery grounds (Wilkinson, 2004). In addition, seagrasses not only help to stabilize the movement of sand, important to protecting the reefs from sedimentation, but also are extremely important as grazing grounds for herbivorous fish and as nursery grounds (Gilmore, 1987; Zieman, 1982 both *In:* DeGeorges, 1990a). Among others, fishes from the families of Pomadasytidae, Lutjanidae and Holocentridae find shelter on the reef during the day and move into the adjacent grass beds at night to feed. The seagrasses also serve as an important food source for marine turtles including the green turtle (*Chelonia mydas*) and the loggerhead turtle (*Caretta caretta*) (W.A.T.S. 1983 *In:* DeGeorges, 1990a).

8.2.4 The Relationship between Coral Reefs and Zooxanthellae

The survival of hermatypic or colonial reef-building corals depends on a symbiotic relationship between coral polyps and unicellular brown algae called zooxanthellae (Figure 8.4). This is described and diagramed in Goreau, Goreau and Goreau (1979) and Buddemeier, *et al.* (2004).

Source: Buddemeier, Kleypas & Aronson (2004) with permission, Pew Center on Global Climate Change.

Figure 8.4: Morphology of typical reef-building coral

The zooxanthellae is a dinoflagellate, which lives inside the coral polyp. It is different from most of its group, which is planktonic (including the infamous red tide which can result in massive fish kills) and important to the aquatic food chain. The zooxanthellae give many of the corals their color. They are also found

in other invertebrates such as giant clams (*Tridacna* spp.) and many nudibranchs (Sea Slug Forum, 2004).

Approximately 94-98% of all organic carbon produced by the zooxanthellae during photosynthesis leaks out of the algal cells to be used as a food source by the coral polyp (Veron, 1986 *In: DeGeorges, 1990a*). The production of carbon greatly increases the rate of reef building by increasing the rate of deposition of the corals' limestone skeleton (CaCO_3). This light enhanced rate of calcification enables the coral reefs to grow faster than they are eroded by the action of the sea and eroding organisms (e.g., parrotfish). It is the major reason why light and thus depth are limiting factors to colonial corals. Zooxanthellae provide the colonial corals with 98% of their total food requirements (Veron, 1986 *In: DeGeorges, 1990a*; Allen & Steene, 1996), the rest being filtered from the water column (Veron, 1986 *In: DeGeorges, 1990a*).

In turn, the zooxanthellae extract phosphates and nitrates from the corals' waste products, thus enabling an entire ecosystem to develop in what would appear to be an unproductive nutrient poor system. The efficient and rapid recycling of these nutrients results in the tropical world's coral reefs being one of the most productive natural and diverse communities, marine or terrestrial (Wood, Ferguson & Johannes, 1975 *In: DeGeorges, 1990a*).

"It was once believed that all zooxanthellae were the same species, *Symbiodinium microadriaticum*. However, recently, zooxanthellae of various corals have been found to belong to at least 10 different algal taxa. Interestingly, zooxanthellae found in closely related coral species are not necessarily closely related themselves, and zooxanthellae found in distantly related coral species may, in fact, be closely related. This suggests that coral and zooxanthellae evolution did not occur in permanently associated lineages. Rather, symbiotic recombination probably shaped the evolutionary process, allowing both symbionts to evolve separately" (Turner 2002).

Ahermatypic or non-colonial corals do not have this relationship. Ahermatypic corals are not limited by light, growing at great depths and obtaining all of their nutrition from the capture of plankton/microorganisms.

8.2.5 Coral Reefs and Related Fisheries

An estimated 25% of the world's fish species are, in some way, dependent on coral reefs that serve as feeding, spawning and nursery grounds and provide shelter (CORDIO, 1999).

"Coral reefs are one of the most important food reservoirs in the ocean, supporting both subsistence and commercial reef fisheries. Although they cover only about 0.2% of the ocean¹⁹³, coral reefs provide habitat for about 10% of the fish caught for human consumption, and they are the spawning grounds for 15% of the world's fish catch. In some areas in the Pacific, reef-based fish and other organisms account for 50% of local daily protein intake. In the Caribbean, over one-half (50%) of the known species of reef-related fish are commercially marketed. For instance, in 1995, the commercial value of domestically (USA) harvested reef fish and shellfish was estimated to exceed US\$ 79.5 million. In the Florida Keys, the commercial fishing industry contributed US\$ 17 million to the local economy. Imports into the U.S. of reef fish for consumption or the aquarium fish trade amount to an additional US\$ 25-50 million annually" (U.S. Dept. of State 2001).

Coral reef fisheries yield at least 10% of the world's fish catches (CORDIO, 1999), which amounts to at least 6 million metric tons of fish catches annually, excluding local sustenance fisheries. Reefs provide 25% of the fish catch in developing countries and employment for millions of fishers (Pomerance, 1999; CORDIO, 1999). Wilkinson (2004) estimates the total global annual fishery yield

¹⁹³ Note: The Ecological Society of America (2000) and Wilkinson (2004) say 1 % of the ocean floor.

from coral reefs is most likely 1.4–4.2 million tones, only 2–5% of global fisheries catches.

“Other ecosystems like up-welling areas produce 50 times more fish than coral reefs. However, reefs do support important fisheries for tropical people with yields ranging from 0.5 to 50 tons/km/year. The catch on remote reefs in the Indian Ocean is around 60 kg/day/person, whereas heavily fished reefs produce less than 3 kg/day/person” (Wilkinson, 2004).

Fish are an important source of animal protein for people. They provide about one-sixth (17%) of the animal protein intake of people worldwide and are the primary source of protein for about 1 billion people in developing countries. Fisheries are under pressure from over-fishing and in nearshore waters from degraded habitat. Over-fishing is occurring because of excessive harvesting capacity in the world's fishing industry. According to one estimate, the level of fish harvest is 30-40% greater than the sustainable level. As a result, about 28% of the world's most important marine fish species have been fished near to or beyond the maximum sustainable yield (GEF, 2002).

Assessments carried out in 1997 and 1998 showed that a majority of the world's coral reefs were severely over-fished and that most high-value organisms were missing (CORDIO, 1999).

As human populations in and around coral reefs increase,

“coral reefs throughout the world are being degraded rapidly, especially in developing countries, and there are widespread concerns about over-exploitation of reef fisheries. As more and more fishers, both traditional and non-traditional, attempt to take fish from reefs, there is an increasing use of destructive fishing methods such as bombs and poisons; this process is known as ‘Malthusian over-fishing’. Another major problem is the growing

international trade for live reef fish for the Chinese restaurant trade. These fish are often caught by mobile fleets using cyanide, and targeting species that are territorial on reefs. This leads to serial depletion of large coral reef fishes, notably the humphead wrasse (Labridae), groupers (Serranidae) and snappers (Lutjanidae), and to reefs devastated by the cyanide poisoning...there is little chance of ‘sustainable reef fisheries’ when the pressures keep mounting exponentially and the likely future scenario is total depletion of many stocks with localized extinctions of some species” (Wilkinson, 2004).

Wilkinson (2004) notes the following.

“Fisheries management methods introduced and enforced by traditional or indigenous management and corroborated by national and international institutions and policies are more likely to succeed. These include strict species-specific management of stocks; application of quotas or legal sizes of fish; reductions in human fishing effort; restrictions on fishing gear, size of fish taken, times and space; and prohibition of methods that are destructive to habitats and small fish. Nevertheless, even fairly low levels of fishing with non-destructive gear will reduce top-level carnivores, and closures in time and space are needed to maintain their populations. Closed areas may range from reefs that are too dangerous to fish, to highly managed tourist or enforced MPAs (marine protected areas)”.

This is similar to rotational hunting, where once the catch per unit of effort falls off, an area is abandoned until stocks decrease, as used by many traditional societies (see Chapter 2, Section 2.1.5, Mobility as a Means of Managing Natural Resources and Chapter 11, Section 11.11.6, Eco-genocide in Southeastern Cameroon, the forest people and the *Dobi Dobi*, more parks and protected areas). It also goes along with the concept of integrating traditional management systems with modern intensive management concepts (see Chapter 9, Section 9.1, THE CULTURAL DIVIDE and Section 9.7.4.1, Traditional management institutions ignored in favor of Western institutions).

8.2.6 Categories and Structure of Coral Reefs

There are three basic kinds of coral reefs in the Caribbean:

- **Fringing reefs** that grow in shallow waters and border the coast closely or are separated from it by a narrow stretch of water;
- **Barrier reefs** that are separated from land by a lagoon. These reefs grow parallel to the coast and are large and continuous. Barrier reefs also include regions of coral formation that include the zones found in fringing reefs along with patch reefs (small reefs), back reefs (the shoreward side of the reef), as well as bank reefs (reefs that occur on deep bottom irregularities). Coral reefs also include reef flats (the area of the reef not exposed), the reef crest, which runs parallel to the coast and is protected from waves, and a coral terrace (a slope of sand with isolated coral peaks). These features are followed by another coral terrace and a vertical drop into deeper waters; and
- **Atolls** are annular reefs that develop at or near the surface of the sea when islands that are surrounded by reefs subside. Atolls separate a central lagoon and are circular or sub-circular. There are two types of atolls: deep sea atolls that rise from deep sea and those found on the continental shelf (Turner, 2002).

These basic definitions hold true for the western Indian Ocean, including East Africa.

8.2.7 Water Quality and Coral Reefs

8.2.7.1 Temperature

Colonial reef-building (hermatypic) coral reefs are found in tropical waters in which seawater temperatures range from 16-36° C (61-97° F) with an ideal range of 23-25° C (73-77° F) (Smith, 1971 *In:* DeGeorges, 1990a). Veron (1995 *In:* Buddemeier, *et al.*, 2004) and Kleypas, McManus and Meñez (1999 *In:* Buddemeier, *et al.* 2004) place the lower temperature limit of these reef-building corals at 18° C (64° F). While it has long been known that low temperatures limit the existence of coral reefs, it has only recently been appreciated that corals have upper temperature thresholds (Goreau & Hayes, 1994; Pomerance, 1999) as a result of global warming (see Section 8.10.1, Global Ocean Warming and Coral Bleaching). Today, water temperature greatly limits the latitudinal distribution of coral reefs to the world's tropics.

8.2.7.2 Salinity

The average salinity of seawater is 35 parts per thousand (ppt.). Corals can survive in salinity ranges between 25-40 ppt (Smith, 1971 *In:* DeGeorges, 1990a).

8.2.7.3 Light and depth

Because of a symbiotic relationship between corals and a brown algae, zooxanthellae, coral reefs are restricted to depths less than 46 meters (150 feet), the maximum depth at which there is adequate light for photosynthesis. The most vigorous growth of corals is at depths shallower than 27 meters (90 feet) where there is sufficient wave action and current to provide oxygen and food to the coral polyps (Smith, 1971 *In:* DeGeorges, 1990a). The most vigorous reef growth

tends to occur in high-energy zones including the windward side of shorelines and the seaward side of the reef where there is heavy surf action and strong currents are present.

8.2.7.4 Nutrient concentrations

“Coral reefs are the most nutrient-sensitive of all ecosystems. They are overgrown by algae at such low levels of nutrients that no other ecosystem would be affected. Water quality standards based on human health permit nutrient levels hundreds of times too high for corals” (Goreau, 2003a).

“In some coral reefs, the proliferation of benthic algae caused by enhanced nutrient inputs has led to competition with the hard corals, which the corals have lost. Thus, there can be a change in community structure from a hard coral dominated to an algal-dominated system” (GESAMP & ACOPS, 2001). “All reefs near human populations or adjacent to large land masses suffer degradation from nutrient pollution” (Wilkinson, 2004).

Goreau (2003a) supports the “bottom-up theory” that nutrients control the production of marine plants, but that herbivores, by eating some plants preferentially and avoiding others (often because they are toxic or too tough), can influence which epiphytic algae are most abundant. He believes that excessive abundance of epiphytic algae can be controlled by reducing nutrients. This is opposed to the “top-down theory” which he believes is often based on poor science and which blames artisanal fishermen for over-fishing herbivores and the die-off of algal consuming sea urchins. In the principal author’s practical experience, he has come to similar conclusions, namely that a major cause of coral die-off globally has been nutrient pollution.

“The distinctions between the two theories are not just an academic quarrel if they affect practical management issues. Following the wrong paradigm will result in failed efforts at control. Because

bottom-up and top-down theories recommend such different policy prescriptions (stopping fishing versus stopping sewage), effective management of algae on reefs will fail if the factor being controlled is not really the most important one" (Goreau, 2003a).

Groups of individuals such as developers, communities and countries can directly address nutrient pollution specifically and land-based pollution in general, usually at a local level, by looking at appropriate sewage technology and working with small-scale farmers to use appropriate soil conservation and other agricultural practices. Ecosystems are classified in terms of nutrients as being (Goreau, 2003a):

- “Oligotrophic” or low in nutrients;
- “Mesotrophic” or intermediate;
- “Eutrophic” or excessive in nutrients. Eutrophic systems are dominated by fast growing epiphytic or benthic algae; and
- “Hyper-Eutrophic” refers to systems that are overwhelmingly dominated by a few species of the worst weeds (epiphytic algae).

Any aquatic ecosystem will go eutrophic if there are enough nutrients, but the nutrient concentrations that cause a coral reef to go eutrophic are so low that the same levels would be oligotrophic in any other ecosystem. For example, the next most sensitive tropical marine ecosystem, seagrasses, require nutrient levels 20 to 30 times higher than coral reefs before the weedy algae overgrow the seagrasses (Lapointe, Tomasko, & Matzie, 1994 *In:* Goreau, 2003a).

“Since almost all published work on eutrophication is in lakes and cold water bays, the nutrient limits for them are commonly, and incorrectly, applied to coral reefs by many uninformed researchers. Environmental water quality standards are inevitably based on cold and fresh waters, making them at the least irrelevant and at worst dangerous if applied to coral reef ecosystems” (Goreau, 2003a).

Nutrient pollution can result from sewage ("brown water"), wash water ("gray water") and agricultural runoff (fertilizer and natural components of the soils) (DeGeorges, 1990a). Other sources include birds nests, turtle and dolphin enclosures/farms, garbage dumps, fish cannery and abattoir wastes, transport by distant watersheds from rivers as is described below for Belize and for the Amazon and Orinoco Rivers in the southeastern Caribbean, massive rain events such as Hurricane Mitch causing runoff from Honduras to the reefs of Belize and Mexico, and seasonal upwelling (Goreau, 2003a). Assuming that this upwelling and associated high nutrient levels are natural, one would have to hypothesize that where this exists along with corals, the latter have evolved around this phenomenon (e.g., ahermatypic corals off the Cape Verte Peninsula of Senegal), unless land-based pollution sources added to the nutrient concentrations of the upwelling reach critical levels.

As described, coral reefs have evolved to thrive in a nutrient poor system in which nutrients are recycled rapidly through the food chain (Section, 8.2.4, The Relationship between Coral Reefs and Zooxanthellae). In the Eastern Caribbean, the following nutrient concentrations are typical of "non-polluted marine waters" (Bellairs Research Institute, 1989 *In:* DeGeorges, 1990a) (Table 8.1).

In a recent publication of the Caribbean Water and Wastewater Association (CWWA),

"work done by Professor Hunte and others clearly indicates that the coastal waters around Barbados, in particular the west and south coasts (heavily populated by residents and tourists) are nutrient-stressed. The situation is likely the same for many of the other islands in the region. In Barbados, the following ambient marine water quality standards for nutrients have been recommended to protect coral reefs" (Sealy, 2002):

Total nitrogen: 10 µg/l or 0.01 mg/l Total phosphorus: 2.5 µg/l or 0.0025 mg/l

Table 8.1: Background concentration in unpolluted Eastern Caribbean waters

Parameter	ug-at/l & mg/l ¹⁹⁴	ug-at/l & mg/l
Nitrate ($\text{NO}_3 + \text{NO}_2$) as N (Unfiltered)	Coastal Waters (Nearshore) 0.70 & 0.01	Oceanic Waters 0.35 & 0.005
Total Phosphate Phosphorus as P (Unfiltered)	0.10 & 0.003	0.06 & 0.002

(ug-at/l as P) x (0.031) = mg/l as P
 (ug-at/l a N) x (0.014) = mg/l as N

Source: Bellairs Research Institute, 1989 *In: DeGeorges, 1990a* with permission, Bellairs Research Institute.

Although not stated, given the information above, these standards would be ug/l and mg/l as N and P, respectively. According to Sealy¹⁹⁵ (2004), these recommended standards were provided by Dr. Wayne Hunte,¹⁹⁶ the same person who had put together the recommended standards above for the Bellairs Research Institute.

Phosphate standards recommended by the Bellairs Research Institute and CWWA above appear to be Total Phosphate Phosphorus, which is Total filterable + Non-filterable Phosphate (APHA, 1976). CWWA's total nitrogen can mean [Total Nitrogen = Total Kjeldahl Nitrogen = (that is organic nitrogen + ammonia)], or Total Oxidized Nitrogen = [sum of nitrate + nitrite nitrogen] (APHA, 1976) which

¹⁹⁴ ug-at/l = umoles/decimeter = umoles/liter = (mg/l) x (1000 ug/mg) x 1 mole/grams molecular weight (14 for N, 30 for P) x (gms/10⁶ ug) x (10⁶ umoles/mole) = 1000/molecular weight (14 for N, 30 for P) x (mg/l). Thus for example (1000/14) x (0.01 mg/l N) = 0.7 umoles/l = 0.7 ug-at/l. Conversely, [(ug-at/l) x (molecular weight)]/1000 = mg/l.

¹⁹⁵ Dr. Hugh Sealy, engineer, Chairman of the National Commission on Sustainable Development, Barbados and former president of the CWWA, hughsealy@yahoo.com

¹⁹⁶Formerly Director of Bellairs Research Laboratory of McGill University in Holetown, Barbados, currently Pro Vice Chancellor [Research], The University of the West Indies, Cave Hill Campus, pvcresearch@uwhchill.edu.bb

is what Bellairs recommends in Table 8.1. Both would be unfiltered. Dr. Hunte (Sealy, 2002) explains that

“the rationale for inclusion of total nitrogen, total phosphorus and chlorophyll-a is increasing concern that nitrite, nitrate and (ortho) phosphate may be poor indicators of nutrient loading of the coastal zone as they are rapidly removed from the water column by algal assimilation”.

This would appear to indicate that Dr. Hunte was recommending Total Kjeldahl Nitrogen and Total Phosphate Phosphorus standards in 2004.

Lapointe (2004a) provides slightly different estimates of recommended nutrient water quality standards to protect coral reefs based on research primarily in the Florida Keys and Caribbean. These recommended water quality standards appear to be based on the latest research (Table 8.2) (Goreau & Thacker, 1994; Goreau 2003a; Lapointe, 2004a; Lapointe 2004b).

Table 8.2: Recommended ambient nutrient water quality standards in nearshore waters, not to be exceeded: “threshold concentrations” to protect coral reefs from overgrowth of epiphytic algae

Parameter	Not Exceeding mg/l (ppm) (umole/l)
Dissolved Inorganic Nitrogen (DIN) = Dissolved (Filterable) [Nitrate (NO ₃) + NO ₂) + Ammonia] as N	0.014 mg/l (1 umole/l as N) ¹⁹⁷
Soluble Reactive Phosphorus (SRP) = Dissolved (Filterable) Orthophosphate as P	0.003 mg/l (0.1 umole/l as P) ¹⁹⁸

Note: umole/l = ug-at/l.

Source: Goreau & Thacker (1994); Goreau (2003a); Lapointe (2004a) & Lapointe (2004b) with permission, Thomas J. Goreau, PhD, president, Global Coral Reef Alliance.

¹⁹⁷ (umole/l x molecular weight)/1000 = (1 x 14)/1000 = 0.014 mg/l

¹⁹⁸ (0.1 x 30)/1000 = 0.003 mg/l

Dissolved parameters should be filtered through a 0.45 micron Millipore Filter (APHA, 1976; Goreau, 2004a.). Lapointe (2004c) believes that

“Total N and Total P are not the preferred indices as they contain particulate forms of N and P that are unavailable to reef biota (i.e., unreactive). The efficacy of these DIN and SRP thresholds was proven in South Florida when water managers pumped massive amounts of farm runoff through the Everglades into Florida Bay and the Florida Keys National Marine Sanctuary (FKNMS) in the mid-1990s...which led to the demise (38% loss of coral throughout the FKNMS between 1996 and 1999 following the nutrient enrichment event) of the 3rd largest coral reef in the world (only ~ 6% coral cover left)”.

With regards to the differences in nutrient data, Goreau (2004b) comments that algae can take up ammonia, nitrate or nitrite. Normally there is very little nitrite in seawater.

“Nitrate is usually much more abundant than ammonia in sea water, but algae will take up ammonia in preference, and this is the form that is prevalent in sewage. As a result it is very variable, and rapidly taken up. Many oceanographers never measure it, and so tend to under-appreciate its importance to algal nutrition. So available nitrogen basically equals the sum of nitrate and ammonia” (Goreau, 2004b).

“It is important to note that to achieve the recommended ambient standard, even with an effluent discharge standard for nitrogen of 10 mg/l as recommended by CEHI (Caribbean Environmental Health Institute), a dilution factor of at least 1000:1 would have to be achieved in the mixing zone around the outfall diffuser. It would appear that even if tertiary treatment with nutrient removal is used, there may still be elevated nutrient levels, harmful to reefs in the immediate vicinity of the marine outfall. Therefore, careful consideration must be given to outfall location and diffuser design, even with tertiary treated wastewater” (Sealy, 2002).

Nevertheless, waters, which exceed these concentrations due to pollution, can exhibit a number of deleterious effects that can cause demise in the coral reef community (Shinn, 1989 *In:* DeGeorges 1990a). These effects include increased blooms of phytoplankton that decrease light penetration in the surface waters and thus decrease the photosynthetic rate of the zooxanthellae, ultimately reducing coral productivity (Hunte, 1987; 1989; Tomascik & Sander, 1987a; 1987b; Woodley, 1987; Woodley *et al.*, 1987; UNEP, 1988 all *In:* DeGeorges, 1990a; GESAMP, 2001). Reduced light penetration from algal blooms can also negatively impact photosynthesis of marine seagrass beds, also resulting in their demise (GESAMP, 2001).

Probably the most observable deleterious effect has been the smothering of the coral reef by epiphytic algae (benthic macro-algae) that cuts off the light needed by zooxanthellae to photosynthesize and prevents the coral polyps from filtering food out of the surface waters (DeGeorges, 1989b; DeGeorges, 1988a; 1988b; DeGeorges & Ford, 1988; Hunte 1987; 1989; Johnson, *et al.*, 1988; MAB, 1989; O'Callaghan, Woodley & Aiken, 1988; Ward, 1990; Woodley, 1987; Woodley, *et al.*, 1987; WWF, 1986 all *In:* DeGeorges, 1990a; Maragos, 1992 *In:* Thayer, 1992; Goreau 2003a; Lapointe, Barile, Yentsch, Littler, Littler & Kakuk, 2004). With all sources of nutrition cut off, the coral reef dies. Lapointe (2004b) notes an N/P ratio of 10/1 linked to the threshold concentrations in Table 8.2 for macro algae to take over.

Goreau (2003a) believes that “the Caribbean has much lower tides and currents than do islands in the Pacific and Indian Oceans, the water sits around much longer and is less diluted. As a result Caribbean islands are much more vulnerable to eutrophication than those in the Pacific and Indian Oceans for the same nutrient input (except for enclosed lagoons)”. Still the principal author's observations from the Red Sea to Mozambique indicate that similar eutrophication with corresponding high epiphytic algal cover and dead coral in nearshore waters, as in

the Caribbean, correlate directly with the level of human population and thus development within the watersheds draining onto these reefs (see Section 8.12, SUMMARY - PERSONAL OBSERVATIONS OF CORAL REEF DEGRADATION IN AFRICA).

Ultimately, Goreau (2003a) is convinced that the only way to stop algae from taking over coral reefs is to cut off the source of nutrient enrichment. The net result of nutrient enrichment “is to push the system to algae that can't be eaten because they are too toxic, too tough, or very dense rapidly growing turf algae that are too short to be grazed” (Littler & Littler, 2000 *In:* Goreau, 2003a). No fish and urchin algal grazers will be able to stop its spread if the source of nutrient enrichment is not stopped!

Lapointe, *et al.* (2004) recommend multi-faceted approaches to study the impacts of nutrient pollution on coral reefs that include characterization of water column nutrient concentrations, algal tissue analysis for C:N:P (carbon:nitrogen:phosphorous) ratios, and tests of algal physiological responses (growth rate, biomass, Alkaline phosphatase activity-APA)^{199,200} to other

¹⁹⁹ Alkaline phosphatase (APA) is the enzyme that releases orthophosphate from dissolved organic phosphorus (e.g. indication of pollution from sewage and/or agricultural runoff) under alkaline conditions, allowing algae to take it up. Dissolved organic phosphorus is the major source of phosphorus for algae in Jamaica. If there is a lot of organic pollution, one expects to find high levels of APA in attempts to create orthophosphate from dissolved organic phosphorous (Goreau, 2004d). Lapointe (1997) found APA activity was in macrophytic (epiphytic) algae. Goreau's father (Goreau, 1953; 1956) showed that coral reefs were exposed to very high levels of APA 55 years ago, having found the enzyme APA in the epidermis of corals (Goreau, 2004d). “It makes sense that it would be a membrane-bound external enzyme to bind to and hydrolyze external organic phosphorus compounds so that the released orthophosphate can be directly taken up across the cell wall” (Goreau, 2005).

²⁰⁰ Alkaline phosphatase (APA) is an enzyme that is produced in relatively large quantities by planktonic algae in response to low orthophosphate concentration in the environment. Low orthophosphate concentration commonly occurs in the photic zone of eutrophic or even mesotrophic freshwater lakes during the growing season. Therefore, at least during the growing season in productive lakes, it should be possible to find an inverse relationship between the activity of the enzyme, alkaline phosphatase, and the concentration of the product of hydrolysis, orthophosphate - the lower the amount of orthophosphate in lake water, the more alkaline phosphatase would be produced/released by algae (Boavida, Hamza, Ruggiu, & Marques, 1997).

researchers attempting to define ecological effects of land-based nutrient enrichment over space and time.

8.3 “BOTTOM-UP” VERSUS “TOP-DOWN” THEORIES EXPLAINING DEVELOPMENT OF ALGAL REEFS

8.3.1 Sea Urchin Dieback

Much of the support for the “top-down theory” - over-fishing being the cause of epiphytic algae overgrowing and smothering coral reefs, resulting in their death - has come from studies after a disease wiped out almost all long-spined black sea urchins or *Diadema* (*Diadema antillarum*) in the Caribbean in 1983. If *Diadema* controlled epiphytic algae, there should have been a sudden Caribbean-wide algal bloom in 1983. This has been claimed in widely cited papers from Jamaica (Hughes, 1994 *In:* Goreau, 2003a), Panama (Shulman & Robertson, 1996 *In:* Goreau, 2003a), and Curacao (de Ruyter van Steveninck & Bak, 1986 *In:* Goreau, 1993).

“In other parts of the Caribbean, areas with nutrient inputs are algae dominated and areas with low nutrients are low in algae, whether or not *Diadema* or herbivorous fish are present. In many parts of the Caribbean *Diadema* populations have now recovered to dense levels, but wherever there are nutrient inputs *Diadema* are

One would expect something similar in marine conditions. When the dominant form of phosphorus available to algae is dissolved organic phosphorus (little orthophosphate available), increased levels of alkaline phosphatase would be found either in tissue (epiphytic algae, coral, phytoplankton) or the water column, though the latter might be rapidly diluted and difficult to measure, in an attempt to produce more orthophosphate for uptake by the algae. Thus, APA is also a good indicator of organic pollution (e.g., sewage, gray water, agricultural runoff) in marine environments.

completely unable to control algae, except in patches just grazed by dense swarms. When nutrients were low, *Diadema* would hide under corals in the day, and hunt for the few algae at night. Now they sit in the open, fat and lazy, grazing a ring around a centimeter or so wide. Beyond the narrow grazed halo lies dense algae forests that the urchins are unable to control" (Goreau, 2003a).

Lapointe (1997; 2004) states that nutrient availability, not consumption by grazers, is a critical factor regulating growth and reproduction of macro (epiphytic)-algae. Nutrient enrichment (bottom-up controls) triggers proliferation of algal turfs and macro-algae in coral reef environments. "Top-Down" proponents of grazers controlling epiphytic algal cover rarely have nutrient data to back up their conclusions (see Section 8.2.7.4, Nutrient concentrations and Section 8.6.2, Montego Bay, Marine Park or Marine Cemetery? A Lesson For Africa). Wilkinson (2004) seems to sit on the middle of the fence, stating that

"over-fishing and particularly fishing with destructive methods are: threatening the normal functioning of coral reef ecosystems; reducing populations of key reef organisms; lowering coral reef productivity; and, along with pollution, shift the advantage towards macro-algae by removing grazing pressure. These algae smother and out-compete corals".

The Jamaica study measured algae and coral cover of the bottom at a single site and reported that algae took over in 1983. Data in that paper show that the transition was not rapid but linear and gradual over many years and began before 1983. The paper claimed the site had no nutrient inputs, citing a study on long-term change in reefs around Jamaica (Goreau, 1992a *In:* Goreau, 2003a). The site was immediately down current from the single largest source of nitrogen on the island: from rivers and springs draining densely populated agricultural areas in the center of the island. In addition, a large dairy cattle operation right next to the site shoveled all the cow manure into the river every morning, where it swept over the

“nutrient-free” site to the extent that one could smell it in the water. “Algae dominance in Jamaica did not take place suddenly everywhere in 1983, but progressively over a 40-year period from the 1950s to the 1990s, following the growth of local population and tourism at each site” (Goreau, 1992a *In:* Goreau, 2003a). The region for which sea urchin die-off was claimed to be the cause of algae coincidentally underwent strong tourism and population growth in the 1980s. “Furthermore, algae overgrowth of corals took place in deep reefs where *Diadema* had never been present in significant numbers, having been almost entirely confined to shallow back reef areas” (Goreau, 2003a) that is algal growth did not take place just because of the *Diadema* die-off but because of landbased nutrient pollution.

Similarly, Goreau (2003a) describes the Panama study mentioned above as being flawed, assuming no nutrient pollution even though the site was in a lagoon draining a highly populated area with direct discharge of sewage. No water quality data were collected. Fifteen years after the coral die back, Goreau, Tribaldos, Gonzalez-Diaz, Arosomena and Goreau (1997 *In:* Goreau, 2003a) found the out-flow side of the lagoon rich in sewage covered in epiphytic algae, while the inward flowing side with clean ocean water was covered with live coral even thought there were no sea urchins.

Goreau (2003a) also labels the Curacao study as being flawed since the deep reef brown algae had been there before the *Diadema* die-off and regardless, the *Diadema* was only ever found in the shallow reefs. “So widely cited have these flawed studies been, that almost all subsequent authors noting high algae have blamed them on post 1983 lack of sea urchins, even when algae dominance took place up to 20 years later or more than 20 years before” (Goreau, 2003a)!

8.3.2 Over-Fishing of Algal Grazers

Goreau (2003a) also believes that this hypothesis as a key reason for epiphytic algae take-over of coral reefs tends to be flawed. He gives the example of Jamaica where,

“coral reefs near urban areas of Kingston, Jamaica were algae dominated in the 1950s, even though *Diadema* were very abundant. A study of Vieques Island, Puerto Rico, found that algae became dominant around 2000, yet blamed lack of herbivores. But algae dominance took place nearly 20 years after the *Diadema* died (around 1983), and was accompanied by a dramatic INCREASE in algae-eating parrotfish, as would be expected if the herbivores were controlled by algae abundance rather than top-down control”.

In the case study presented in this chapter, The Nature Conservancy (TNC)²⁰¹ blamed the poor artisanal fishermen in Montego Bay for over-fishing algal-grazing fish, resulting in increased algal cover and dead reef.

“The pattern in Jamaica rejects the hypothesis that over-fishing has removed the herbivores. In the 1950s and 1960s when the reefs were already over-fished, they were coral dominated with little or no algae except around the highly polluted Kingston urban area. Fish populations were dominated by dense schools of species that eat other fish or eat coral reef animals such as crabs, shrimps, worms, etc. But as the reefs became algae dominated these foods vanished, and the reef fish became dominated by fish that eat algae, because there was no other food available. So, far from the algae being due to lack of animals to eat them, it seems that abundance of algae have instead caused an INCREASE in the number of fish that eat them, indicating that the fish are under bottom-up control by algae” (Goreau, 2003a).

²⁰¹ The Nature Conservancy, 4245 North Fairfax Drive, Suite 100, Arlington, VA 22203-1606, Tel: (703) 841-5300, comment@tnc.org <http://nature.org/aboutus/>.

Likewise, in the Bahamas, Lapointe, *et al.* (2004) found

“low coral cover (< 2%) co-occurred with high macro-algal cover (>35%) at DIN (Dissolved nitrate + nitrite + ammonium)-enriched reef sites around Norman’s Pond Cay (Waterfall, Patch Reef, North Perry Reef) compared to relatively high coral cover (10–20%) and low macro-algal cover (< 20%) at the lower DIN reef sites (Rainbow Reef, Lang’s Reef). These results support ecological theory that bottom-up control via nutrient enrichment is a primary factor regulating overall biomass and taxonomic assemblages of macro-algae on coral reefs, whereas grazing is more important in controlling relative species composition via dietary preferences”.

“The same pattern is seen in coral reefs all around the Caribbean, Indian Ocean, and Pacific: dense populations of algae-eating fish and sea urchins are found only at sites that have a lot of algae. While diseases and over-fishing can result in removal of herbivores, dense algae populations are found at all sites with nutrient sources, and are very low where these sources are absent, whether or not herbivores are present” (Goreau, 2003a).

The principal author found *Diadema* flourishing on the nutrient polluted, epiphytic algal covered dead reefs of Grand Anse Beach, Grenada in the late 1980s. The only area cleaned of algae, though exposing dead reef, was where *Diadema* were concentrated.

8.3.3 Caribbean Fishermen Victims or Culprits – Lessons for Africa

As for the fishermen, although they are a part of the problem and need to be helped in better managing their marine resources, they are not believed to be the major culprit in the demise of the Caribbean's coral reefs. In fact, it might be argued that they are the victims of insensitive northern temperate climate developers, who lack understanding of how tropical coastal waters function ecologically, thus failing to use appropriate technologies to address sewage and gray water issues. They also tend to use large amounts of fertilizers on lawns and

golf courses that drain onto coral reefs and grass bed ecosystems and have a history of building too close to beaches, which impacts on the sex ratio and survival of sea turtle hatchlings.

Fishing on reefs can be classified into three stages: manageable, ecosystem-over fished and Malthusian-over fished. Fishing with blasting devices and poisons is often associated with the third stage. Supporters of the “top-down” hypothesis believe that over-fishing of grazers or herbivores can lead to the proliferation of epiphytic algae, especially in areas subject to nutrient rich runoff, which stimulates algal growth at the expense of corals and results in a coral algal phase-shift (McManus, Meñez, Kesner-Reyes, Vergara & Ablan, 2002). This, however, will likely occur even without over-fishing if nutrient pollution is a problem (Goreau, 2003a; Lapointe, 2004b; Lapointe *et al.*, 2004), this being the “bottom-up” hypothesis of coral reef degradation. McManus, *et al.* (2002) disagree with Goreau (2003a), stating that cage studies indicate that reduction in herbivory can lead to the proliferation of algae even in the absence of eutrophication. In other words, they believe that removing herbivorous fish such as parrotfish from over-fishing and/or other causes can result in significant increases of epiphytic algae, even without nutrient pollution. A major concern with the widespread coral bleaching associated with the 1997-1998 El Niño event is the likelihood that reefs already stressed by over-fishing and organic pollution may not return to coral dominance after severe bleaching (McManus, *et al.*, 2002).

The principal author tends to support the “bottom-up” hypothesis based on his professional experience. Certainly, kicking fishermen out of marine parks is not the solution, unless this is part of a more holistic approach, which integrates the fishermen into the overall management of the coral reef (e.g., working as dive and glass-bottom boat operators in marine parks or becoming involved in sustainable artisanal and sportfishing outside of the marine parks).

8.4 CORAL REEFS UNDER THREAT

“Some 2.2 billion people, nearly 40% of the world's population, live within 100 km of a coastline. These people exert significant pressures on coastal and marine ecosystems that can adversely affect the ecosystems' integrity and function. These pressures include harvesting of natural resources, such as fish and mangrove forests; infrastructure development; and industrial, agricultural, and household pollution. Coastal habitats or resources that are under severe threats from human activities include mangrove forests, coral reefs, and fisheries” (GEF, 2002).

Other analyses estimate that almost half a billion people, 8% of the total global population, live within 100 kilometers of coral reefs (Bryant, Burke, McManus & Spalding, 1998; U.S. Coral Reef Task Force, 2000), just under 150 million of these people being found along the Indian Ocean (Bryant, *et al.*, 1998).

GESAMP (2001) estimated that 70% of the world's coral reefs were under threat by humans and their actions such as pollution, land reclamation, felling forests, mining, building on coasts, destructive fishing (e.g., poison, explosives or catch-all nets), reef mining and the aquarium and curio trades. This chapter analyzes many of these threats.

The most severe threats to coral reefs stem directly from human activities. These impacts are exacerbated by degradation of the overall marine environment due to global climate change (U.S. Coral Reef Task Force, 2000; Wilkinson, 2004). By 1997, an estimated 11% of the world's reefs had been lost to a variety of human activities including shoreline development, polluted runoff from agricultural and land-use practices, over-harvesting, dynamiting and other destructive fishing over-fishing, poorly located and planned coastal tourism developments and ship groundings. In 1998, a massive climate-related coral bleaching event destroyed or degraded an additional 16% of the coral reefs of the world (Evans, 2002;

Buddemeier, *et al.*, 2004) (see Section 8.10.1, Global Ocean Warming and Coral Bleaching).

Widespread coral bleaching, unknown before the 1980s, has brought recognition that reefs are threatened by global-scale climate factors as well as by more localized threats and that different types of stress may interact in complex ways (Buddemeier, *et al.*, 2004). It is estimated that an additional 32% of the world's coral reefs are now seriously threatened. In 2000, the Global Coral Reef Monitoring Network (GCRMN) estimated that 27% of all coral reefs were effectively lost (Evans, 2002). Wilkinson (2004) estimates that 20% of the world's coral reefs have been effectively destroyed and show no immediate prospects of recovery. CORDIO (1999) states that human activities, particularly land-based pollution and coral mining potentially threaten an estimated 58% of the world's coral reefs. In 2004, the Global Coral Reef Monitoring Network (GCRMN) estimated that (The Washington Post, 2004) (Table 8.3):

- 20% of the world's coral reefs have been destroyed and show no immediate prospect for recovery;
- 24% are under imminent risk of collapse through human pressures; and
- 26% are under a longer term threat of collapse.

"Experts from each region, as well as people with considerable experience provided the assessments. However, these assessments should be regarded as indicative, because there are insufficient coral reef monitoring data for many of these regions to make definitive statements on losses and authoritative predictions on the future" (Wilkinson, 2004).

Table 8.3: Summary of the current status of coral reefs in the 17 regions of the world designated as nodes within the Global Coral Reef Monitoring Network (GCRMN)

Region	Area km ²	Destroyed Reef (%)	Reef Recovered %/Reef Destroyed in 1998	Reefs at Critical Stage (%)	Reefs at Threatened Stage (%)	Reefs at Low or No Threat Level (%)
Red Sea	17,640	4	2/4	2	10	84
The Gulfs	3,800	65	2/15	15	15	5
East Africa	6,800	12	22/31	23	25	40
SW Indian Ocean	5,270	22	20/41	36	31	11
South Asia	19,210	45	13/65	10	25	20
Southeast Asia	91,700	38	8/18	28	29	5
E & N Asia	5,400	14	3/10	23	12	51
Australia, PNG	62,800	2	1/3	3	15	80
SW Pacific Islands	27,060	3	8/10	18	40	40
Polynesian Islands	6,733	2	1/1	2	3	93

Hawaiian Islands	1,180	1	NA	2	5	93
U.S. Caribbean	3,040	16	NA	56	13	15
North Caribbean	9,800	5	3/4	9	30	56
Central America	4,630	10	NA	24	19	47
East Antilles	1,920	12	NA	67	17	4
South Tropical America	5,129	15	NA	36	13	36
TOTAL	284,803	20	6.4/16	24	26	30

- 1) Destroyed Reefs (%) = 90% of corals lost and unlikely to recover soon
- 2) % Reefs recovered/% reefs destroyed dates from 1998 bleaching event
- 3) Reefs at critical stage (%) = 50-90% coral loss and likely to fall into Destroyed Reef category in 10-20 years
- 4) Reefs at threatened stage (%) = 20-50% of coral loss and likely to reach Destroyed Reef Stage in 20-40 years
- 5) NA: Not applicable, no losses in 1998

Source: Wilkinson (2004) with permission, Australian Institute of Marine Science (AIMS).

In other words, 20% of the world's coral reefs have been destroyed and another 50% are heading in that direction, leaving only 30% of the world's coral reefs in a very healthy state as of 2004. Goreau (2005) believes that many of these

"estimates are too low as they are based largely on measurements started only after much of the coral was gone, and not based on knowledge or photographs of how the reefs used to be".

A total of 40% of the world's coral reefs may be lost by 2010; particularly those near human populations, and if current pressures continue unabated, 58% may be lost by 2030, unless urgent management action is taken to reduce human impacts on reef ecosystems (Evans, 2002). However, in many areas, the trend in coral reef health is downward and these ancient ecosystems are in peril. In other areas, there is no adequate monitoring and information to assess the reef condition or determine the effectiveness of management actions (Evans, 2002).

Wilkinson (2002) estimates that globally the mean hard coral cover is only 32% with the percent hard coral cover being significantly higher on reefs having no anthropogenic impacts. Algal cover was higher on reefs rated as having high sewage inputs. It is estimated that the live coral cover on many reefs in the Caribbean declined from an average of 50% 30 years ago to an average of 10% at present (Gardner, Côté, Gill, Grant & Watkinson, 2003 *In: Buddemeier, et al.* 2004). Wilkinson (2004) estimates that coral cover on many Caribbean reefs has declined by 80%, though there is some sign of recovery.

"The regional pattern of decline is alarming; with coral cover decreasing from more than 50% on average in 1977 to approximately 10% in 2001, i.e. a loss of 80% in 25 years... There are currently 116 million people living within 100 km of a Caribbean coast, which is a 20% increase in the past 10 years. These pressures and the threats of global climate change pose a potential major threat for the future" (Wilkinson, 2004).

Bryant, *et al.* (1998) indicate that just under 60 million people live near the coast in the Caribbean. It is estimated that in the Caribbean (Wilkinson 2004):

- 64% of Caribbean coral reefs are threatened by high levels of human activities, especially the Eastern and Southern Caribbean, Greater Antilles, Florida Keys, Yucatan, and the Mesoamerican Barrier Reef;
- Coastal development threatens 33% of the region's reefs. The threat is greatest in the Lesser and Greater Antilles, Bay Islands of Honduras, Florida Keys, Yucatan, and Southern Caribbean;
- Land-based sources of pollution and sediments threaten 35% of Caribbean coral reefs, most notably Jamaica, Hispaniola, Puerto Rico, the high islands of the Lesser Antilles, Belize, Costa Rica, and Panama;
- Pollution and damage from ships threatens 15% of coral reefs, especially around large ports and cruise tourism centers. Over-fishing threatens more than 60% of Caribbean coral reefs, particularly on narrow coastal shelves near human population centers;
- Diseases and rising sea surface temperatures threaten reefs across the Caribbean.
- Ineffective MPA management threatens Caribbean coral reefs with only 6% of 285 MPAs rated as effectively managed; and
- There will be large economic losses if coral reef degradation continues with a predicted loss of \$350-870 million per year by 2015 of the US\$ 3,100 million to \$4,600 million of current annual benefits from fisheries, dive tourism, and shoreline protection services.

There is concern that coral reefs in the Caribbean recover more slowly from various stresses than Indo-Pacific Reefs (Sammarco, 1985; Kojis & Quinn, 1994; Done, 1999 both *In: Buddemeier, et al., 2004*), possibly due to the small size of

the Caribbean, which is to a large part impacted by land-based pollution that to date is not decreasing. This makes it difficult for replacement larvae from upstream reefs to recolonize since pollution prevents recolonization. In addition, many of the upstream reefs themselves are also degraded since so much of the Caribbean is situated close to heavily populated land masses so that larvae are not readily available for recolonization, prolonging the monopolization of coral reefs by epiphytic (macro) algae (Buddemeier, *et al.* 2004).

Among the high biodiversity Indo-Pacific reefs, those of Southeast Asia (Indonesia, Philippines, and surrounding areas) have been impacted by land-based pollution and destructive fishing practices such as dynamite and cyanide (see Section 8.10.4, Coral and The Aquarium Trade). They have the advantage of a higher biodiversity and a large scale through flow of ocean water and neighboring reef systems that can provide larvae to recolonize (Burke, Selig, & Spalding, 2002 *In: Buddemeier, et al., 2004*). Elsewhere in the Indo-Pacific, coral reefs are not currently subjected to major anthropogenic impacts (land-based pollution and destructive fishing practices) (Buddemeier, *et al.*, 2004), Pacific and Australian reefs remaining healthy (Wilkinson, 2004), and therefore will be more likely impacted by climate change (Buddemeier, *et al.*, 2004).

Human pressures continue to increase the risk of coral reef degradation in the Indian Ocean (Wilkinson, 2004). Off East Africa, it is estimated that 12% of the 6,800 km² of coral reef has been destroyed, while 23% is critical risking to be destroyed in the next 10-20 years, 25% threatened with risk of destruction in the next 20-40 years and 40% under no threat (Table 8.3). This provides the East Coast of Africa, ample opportunity to deal with issues such as land-based pollution and destructive fishing practices (e.g., dynamiting on reefs off Tanzania) at a local level before they become major problems, while globally the world tries to address global warming and the related factors discussed above. More detailed

discussions and personal observations of the principal author concerning the health and condition of East African coral reefs are contained in Section, 8.11 COASTAL DEGRADATION EAST AFRICA AND SOUTHWESTERN INDIAN OCEAN and Section, 8.12 SUMMARY - PERSONAL OBSERVATIONS OF CORAL REEF DEGRADATION IN AFRICA.

8.4.1 Rising Concern Over the Health of Coral Reefs and Related Ecosystems

To combat the serious threats to coral reefs worldwide, the under secretary of state, Timothy E. Wirth, announced the establishment of the International Coral Reef Initiative (ICRI) in 1994. The U.S. State Department hosted the ICRI Secretariat until 1996 and continues to play a central role in the Initiative. ICRI was designed as a partnership of local communities, scientists, conservation groups, resource users, private interests and governments working to protect and manage coral reef resources including associated ecosystems such as seagrass beds and mangroves. Key objectives include:

- Global reef monitoring;
- Reef management;
- Decrease threats to coral reefs; and
- Public education.

Initiative partners are expanding efforts to reduce the physical changes inflicted on fragile reef communities whether they are due to land-based or marine pollution, ship and anchor impact, alien species, temperature and sea level fluctuation or destructive fishing practices. The most significant global-level effort to address land-based sources of marine pollution is the Global Program of Action (GPA). The U.S. State Department hosted negotiations for the Global

Program of Action in 1996. The Global Program of Action is designed to guide states and regions in developing responses to pollution and physical alterations caused by land-based activities (U.S. Dept. of State, 2001).

In 2000, the International Reef Action Network (ICRAN) was formed. ICRAN is a global partnership of reef experts who are working to halt and reverse the decline of the health of the world's coral reefs. ICRAN has three major goals (UN Foundation, 2001):

- Reef Management;
- Global coral monitoring; and
- Communications and knowledge dissemination.

The authors have seen little evidence so far of an awakening to the crisis on the ground by decision-makers and developers with regard to how coasts and their watersheds are developed, where coral reefs are at issue.

8.5 LAND-BASED POLLUTION

As discussed, a major threat to coral reefs globally is land-based pollution, including sewage from coastal development and degraded watersheds from agricultural runoff and over-grazing (DeGeorges, 1990a; Bryant, *et al.* (1998); CARICOM, 1998; GEF, 2002; Coral Reef Alliance, 2002b). All regions of the world report human factors behind much of the reduced coral cover and declining health of coral reefs, especially from sediment, nutrients and toxic compounds, most originating from land-based pollution and over-exploitation of reefs and related resources including fish, invertebrates, coral, algae and sand, with alarming failures in coral recruitment (Wilkinson, 2002), which is to be expected until the source of pollution and/or degradation is removed. "Coral reefs around

the world continue to decline from increasing human pressures; poor land management practices are releasing more sediment, nutrients and other pollutants that stress reefs" (Wilkinson, 2004).

Land-based pollution as described by the principal author (DeGeorges, 1990a) includes both coastal (e.g., sewage, gray water and coastline modifications by coastal strip development primarily for tourism, urbanization and to a lesser degree industry) and land-based pollution (nutrient, sediment, and pesticide non-point source pollution originating from inland deforestation, agriculture and urbanization-related activities) categories. Thus, land-based pollution would account for over 50% of the key causes for coral reef degradation as described in Bryant, *et al.* (1998). Even with global ocean warming becoming more of a factor, it can be argued that the basis of this is land-based and human-induced.

The U.S. State Department estimates that land-based pollution accounts for 80% of all marine pollution. On a worldwide scale, only a fraction of the total domestic waste receives proper treatment and disposal and ultimately is deposited untreated in coastal waters. These activities result in degraded water quality, reduced light levels (affecting growth) and eutrophication of reef communities (e.g., epiphytic algae smothering reef) (U.S. Dept. of State, 1998a; b; U.S. Dept. of State, 2001). The primary means to address this problem is through sound coastal development based on integrated coastal and water resource/watershed management (U.S. Dept. of State, 1998b).

Pollution enters reef ecosystems in many ways, ranging from specific point sources such as sewage pipes and vessel discharges to more diffuse runoff from land-based sources such as agriculture, coastal development, road construction and on-site wastewater management systems, to airborne sources such as emissions from automobiles and power plants. Excess nutrient loading from

inadequate treatment and disposal of human and animal waste and surface runoff from urban and agricultural lands can also lead to significant changes and damage to the reef community. Discharges of oil, garbage and ballast water from vessels can also impact coral reef species. Marine debris from fishing or other sources also has impacts on some reef ecosystems (Evans, 2002).

The World Bank has raised the concern that

“we need effective management systems, like integrated coastal zone management, representative systems of marine protected areas--including no take fishery reserves--, and the control of point and non-point pollution. If such systems are not put in place, and soon, in the more than 90 coral reef countries around the world, we can expect to see even more rapid declines in the health of coral reefs in the next decade than what we witness today. The future would be dim: further losses in live coral cover, reefs overgrown by algae and a few dominant species, and the absence of large fish, including top predators like sharks and grouper” (World Bank, 1997).

8.5.1 Belize and Land-Based Pollution, Lessons for Africa

The principal author first dived and photographed the coral reefs of Belize in 1973 as a Peace Corps volunteer and a member of the El Salvador branch of the British Sub-Aqua Club (BSAC). The reefs were virgin, very few people ever having dived them. He returned to Belize in 1989, as environmental advisor to USAID, to find wide spread degraded reef.

While coral reef degradation on Caye Caulker and Ambergris Cay could be attributed to inappropriate sewage and over-development, many other areas (e.g. in the south from Dangriga/Stan Creek to the border with Guatemala) could not.²⁰² The principal author and the Caribbean forester²⁰³ for the U.S. Forest

²⁰² See (see Table 8.6) below

Service used oral history, based on interviewing local fishermen, to obtain an idea as to potential causes that have brought about this change in coral reef dynamics (DeGeorges, 1989b).

Most fishermen were convinced that illegal fishing was the primary cause for the decline in lobster and conch yields. However, fishermen agreed that where the “rock” (that is coral) died, the lobster left. As one fisherman put it, “when the lobster’s house gets dirty he leaves”. Many fishermen began observing changes in the structure of the coral community, some placing these at seven to eight years earlier (1981/82) while others estimated that changes started taking place four to six years earlier (1983-1985). The change observed by the fishermen was an increase in algal cover locally known as morasse and a gradual dieback of the elkhorn coral (*Acropora palmata*), known locally as pantia or moose coral. They said that when the elkhorn coral dies, the lobster does not come back (DeGeorges, 1989b)! This could have been from a combination of the “white band” disease that is known to have killed *Acropora* spp. and pollution resulting in high algal cover (see Section 8.10.2, Coral Diseases).

8.5.1.1 Red tide

According to the fishermen, about 10-12 years earlier (1977-1979) a red tide that lasted two weeks occurred up and down the coast of Belize and resulted in a massive die-off of finfish. Red tide is caused by a massive bloom of dinoflagellate plankton, which is toxic to finfish. “The key dinoflagellate which causes red tides in the Gulf of Mexico is Gymnodinium breve, reclassified as Karenia brevis” (Mote Marine Laboratory, 2003).

²⁰³ Dr. Loren B. Ford, Strategic Planning and Resource Assessment, USDA Forest Service Stop 1129, 1921 North Kent Street Room 602, Arlington, VA 22209, lbford@fs.fed.us

“At least three harmful effects can result from red tides: oxygen depletion of surface waters leading to mass mortality of larger invertebrates and fish; ingestion of toxic dinoflagellates by shellfish that concentrate the neurotoxins in their tissues, often leading to paralytic poisoning of their predators (including humans); and liberation of neurotoxins into the seawater by the dinoflagellates creating poisoned water, often resulting in skin irritation to swimmers and surfers” (Williams, 2002).

The Texas Department of Parks and Wildlife (2003) also states, “this organism produces a toxin that affects the central nervous system of fish so that they're paralyzed and can't breathe resulting in fish deaths”.

Causes of red tides are complex; some link it to increased freshwater runoff – low salinity, increased surface temperatures and increases in nutrient levels (Massachusetts Dept. of Public Health, 2003; Texas Dept. of Parks; Wildlife, 2003). Williams (2002) states,

“Complex combinations of environmental factors can generate blooms or rapid population growths of certain marine dinoflagellates. These may include: increased levels of nutrients and certain trace metals in the sea water, sewage runoff and other marine pollution, the meeting of two bodies of water with different physical characteristics, ocean salinity and warm sea temperatures, and duration and intensity of sunlight”.

According to the fishermen, the red tide off Belize killed most finfish except shark and barracuda (e.g., snapper, grouper, triggerfish, parrotfish and reef fish in general died). Lobster and conch populations were not noticeably affected. Many of these fish populations never recovered, especially the parrotfish. Parrotfish are important in grazing algae and coral polyps. Could their decline be linked to this problem? The fishermen did not actively fish for parrotfish except for the rainbow parrotfish, *Scarus guacamaia*, which was only fished during the Lenten season for sale in Honduras and Guatemala.

One year after the red tide, there was a tremendous increase in finfish and lobster yields. Then the finfish and lobster catches dropped and as of 1989 have not returned to pre-red tide yields. Interestingly enough, the red tide had not occurred before nor has it since (Bradley *pers. comm.*; Gonzales, *pers. comm. In:* DeGeorges, 1989b). Could the die-off of algal grazers on the reef from the red tide have resulted in an explosion of algal cover, reef die-off and thus habitat loss, resulting in decreased fish and lobster production and catches? The principal author would argue not by itself, but if in combination with nutrient pollution, yes; this is the “bottom-up” hypothesis supported by the principal author and other key researchers (see Section 8.5.2, Land-Based Pollution, Jamaica, Lessons for Africa, Section 8.3.1, Sea Urchin Dieback and Section 8.3.2, Over-Fishing of Algal Grazers).

8.5.1.2 Increase in minute “brown rods” in water during flood season

From the fishermen’s descriptions, this sounded like an annual bloom of phytoplankton associated with flooding and land-based pollution (DeGeorges, 1989b).

8.5.1.3 Increase in land-based pollution from within Belize’s frontier

Commercial fishermen, Villamar Godfrey and Harry Eiley (*pers. comm. In:* DeGeorges, 1989b), could remember that 15-20 years earlier when most of the rivers in the south were covered with natural vegetation, waters ran relatively clear even during the flood season. With the onset of increased conversion of lands to citrus and banana production by American companies, a significant increase in “dirty water” during the rainy season was observed coming from:

- North Stann Creek (Dangriga);

- South Stann Creek;
- Sittee River;
- Mango Creek; and
- Monkey Creek.

Concurrently, large numbers of refugee farmers, primarily from El Salvador, but also Guatemala, Nicaragua and Honduras, were flocking into Belize to escape economic turmoil and strife from these war torn countries. These *campesinos* practiced primitive slash and burn agriculture, especially along Hummingbird Highway that drains into the Belize and Siburn Rivers. U.S. Peace Corps staff felt that the refugee problem and this form of agriculture were the biggest threat to the natural resource base of Belize (Lou Miller & Steve White, *pers. comm. In:* DeGeorges, 1989b). Lou Nicolait (*pers. comm. In:* DeGeorges, 1989b) had observed slash and burn agriculture causing heavy sedimentation in the coastal zones coming out of the Sittee River and the Bladen and Swazee Rivers on the Monkey River.

Sometimes the water was so discolored that it could be observed to reach clear out to the barrier reef, making diving impossible. The fishermen were worried about pesticides, silt and fertilizers in this water that could be killing the reef. Many fish and invertebrates from the coral reef and even some species of grouper and snapper are believed to spend a portion of the life-cycles in the mangrove estuaries off these rivers and backwater patch reefs behind the barrier islands, all of which could be degraded by degraded watersheds and runoff with heavy sediment loads and other pollutants (DeGeorges, 1989b).

In 1999, sugar exports amounted to about 104,000 tons valued at US\$ 41 million. Export earnings from citrus concentrate amounted to \$37 million, representing an increase of \$2.2 million in export earnings over 1998. Banana production also

increased, from 51,824 tons in 1998 to 56,289 tons in 1999 with a value of \$27.3 million (Bailey, Taylor & Fairchild, 2001). It is fine that such agro-industries exist, but assurances must be made that this is not at the cost of the natural environment. Thus, one could argue that Belize, like Africa, is being plundered by Western multi-nationals for short-term gains with little or nor regard for long-term consequences on the overall environment of the region! It would be interesting to know if they adhere to the same environmental standards as in the USA!

8.5.1.4 Possible increase in land-based pollution from outside Belize's frontier

The fishermen observed that each September currents carrying “dirty water” coming from the Gulf of Honduras clouded over the barrier reef. Deforestation and watershed degradation in the Gulf of Honduras (Guatemala and Honduras) was and probably still is a major problem (DeGeorges, 1989b). Andrefouet, Mumby, McField, Hu and Karger (2002 *In:* Lapointe 2004) using satellite imagery observed the same phenomenon of sediment and nutrients flowing over Belize’s reefs from Honduran rivers after Hurricane Mitch in late October 1998. Lapointe (2004c) believes that the recurrent sedimentation and nutrient enrichment from these events helps explain the recent phase shift from hermatypic corals to macro-algae in the Glover Reef’s Lagoon, Belize.

8.5.1.5 Sea urchin die-off, Belize

The fishermen observed that five to six years earlier (1984-1985) there had been a massive die-off of the long-spined black sea urchin, *Diadema antillarum*, as occurred over the entire Caribbean. Some fishermen said the die-off was three years earlier (1982-1981), but everyone agreed that there had been a die-off. The

Diadema is a grazer and its disappearance can result in increased algal growth on corals (DeGeorges, 1989b). Some researchers believe that the sea urchin succumbed to a viral disease after being weakened by pollution (Ward, 1990; Shinn, 1989 all *In:* DeGeorges, 1990a; Maragos, 1992 *In:* Thayer, 1992). See Section 8.3.1, Sea Urchin Dieback for further discussion on this topic.

8.5.2 Land-Based Pollution, Jamaica, Lessons for Africa

The following case study is extracted from Goreau (2003a), whose father was one of the pioneering coral reef ecologists, extensively studying Jamaica.

“The historical process of coral reef eutrophication is best known from Jamaica, where it has been followed around the island for over 50 years (Goreau, 1992a *In:* Goreau, 2003a). Reefs inside Kingston Harbor, next to the island's greatest concentration of people, were eutrophic in the 1950s and died soon afterwards. Reefs outside the harbor went eutrophic by the 1960s, followed by those of the rapidly expanding tourist towns, Montego Bay in the 1960s, and Ocho Rios in the 1970s. In the 1980s the smaller north coast tourist towns went eutrophic, including the reefs near the Discovery Bay Marine Laboratory. The Negril area and the more remote parts of the island went eutrophic in the 1990s, by which time the only non-eutrophic areas left were along the extremely rugged east coast, with few people because of the high wave exposure, lack of flat land, and extremely rainy climate. At all of these sites the same pattern was seen. Algae species were zoned by nutrient preferences around the point sources of pollution like sewage outfalls, river mouths, and springs, and these zones spread outward from them. With time until they merged and the sources could no longer be clearly seen from the algae distributions (Goreau, 1992b *In:* Goreau, 2003a). Coincident with this process of benthic algae blooms smothering reefs, the water turned from clear blue to dark and green as visibility declined due to phytoplankton blooms.

Ironically, despite the long observations of these trends in Jamaica, the island has also been the key study site for many papers claiming that the cause of algae is low herbivory even though the

fish are now almost entirely herbivorous and the sea urchins have recovered in many places. These studies, almost all based on one time or short-term observation of fish and sea urchins, at one or a few sites without nutrient data, by short-term foreign visitors, have all ignored the long term Jamaican literature on the subject”.

8.5.3 Land-Based Pollution, Kaneohe Bay, Hawaii, Lessons for Africa.

The reefs of Kaneohe Bay Hawaii, where sewage flowed directly into the sea, went eutrophic in the 1970s. The pattern of spread of epiphytic algae from the outfalls indicated that sewage nutrients were the cause (Banner, 1974 *In:* Goreau, 2003a). A very long, deep and expensive sewage outfall pipe dumped the sewage far away at sea, where prevailing current kept it from coming back or from affecting other areas. The algae died back quickly and over the next decade the corals gradually recovered, though not to the previous level of diversity or density (Smith, Kimmerer, Laws, Brock & Walsh, 1981 *In:* Goreau, 2003a). By the 1990s, the human population increase in the watershed resulted in a buildup of nutrients and the system again went eutrophic (Laws & Allen, 1996; Larned & Stimson, 1996 both *In:* Goreau, 2003a). Though the point source of nutrients was eliminated, non-point nutrient source runoff from road runoff, lawn fertilizers and golf courses built up to the point that epiphytic algae again overwhelmed the coral reef. This shows that while algae can be starved, the nutrients must be kept permanently low for long-term success (Goreau, 2003a).

8.6 DOMESTIC SEWAGE AS A KEY COMPONENT OF LAND-BASED POLLUTION

Reefs exist in nutrient-poor environments and for that reason small changes in the nutrient content of the water can adversely affect their survival (Ecological Society of America, 2000). Domestic wastewater discharges are one of the most significant threats to sustainable coastal developments worldwide (Spalding, *et*

al., 2001). The effects of individual domestic wastewater discharges are usually localized, but they are a major source of coastal and marine contamination in all regions and therefore a global issue. Pathogenic organisms in domestic wastewater-contaminated marine and estuarine waters cause massive transmissions of infectious diseases to bathers and consumers of raw and undercooked shellfish with a global economic impact recently estimated at US\$ 10 billion/year (GESAMP & ACOPS, 2001).

Environmental effects associated with domestic wastewater discharges are generally local with transboundary implications in certain geographic areas. The commonality of sewage-related problems throughout coastal areas of the world is significant. Consequently, domestic wastewater discharges are considered one of the most significant threats to coastal environments worldwide. The priority for action on “sewage” was identified by (GPA, 2002):

- The Global Program of Action for the Protection of the Marine Environment from Land-Based Activities (Washington, 1995) (see, 8.3.1, Rising Concern Over the Health of Coral Reefs and Related Ecosystems.);
- Seven regional workshops of government-designated experts held in the period 1996 - 1998 in the framework of UNEP’s Regional Seas Program and involving more than 60, mostly developing, countries; and
- UNEP Governing Council (decision 20/19B.1.d) which requested the executive director, in cooperation with other relevant organizations, to explore the possibility of convening a global conference to address sewage as a major land-based source of pollution affecting human and ecosystem health.

As a response to these identified priorities, the GPA Coordination Office, in close collaboration with the World Health Organization (WHO), Habitat (UNCHS -

United Nations Centre for Human Settlements - Habitat) and the Water Supply and Sanitation Collaborative Council (WSSCC), developed a Strategic Action Plan on Municipal Wastewater and supporting documentation (GPA, 2002).

8.6.1 Inappropriateness of Septic Tanks, Secondary and Tertiary Treatment of Human Wastes in Tropical Waters, Lessons for Africa

Where they exist in the Caribbean, sewage treatment plants have been designed by North American and European engineers who are unaware of the extreme nutrient sensitivity of coral reef ecosystems. Their design (e.g. trickling filter and activated sludge) has typically been undertaken to meet secondary treatment levels. Money is usually put into construction of an expensive plant and sewerage. What little money remains is put into a short outfall under the assumption that public health risks have been minimized (Archer, 1988; UNECLAC, 1985 *In: DeGeorges, 1990a*).

In the case of tourist resorts, most developers use prefabricated sewage treatment “package” plants, also designed to attain secondary levels of treatment or they use septic tank systems. In both instances, effluent is discharged close to shore and/or enters into the nearshore waters indirectly through drainage ditches or through groundwater percolation (Ward, 1990; Archer, 1988 both *In: DeGeorges, 1990a*).

Septic tanks in coastal areas with high groundwater tables often malfunction during heavy rain events, flushing huge quantities of untreated effluent into coastal waters. There are even reported instances of “honey dippers” (trucks that haul septic tank sludge) dumping septic tank sludge, a major solid waste disposal problem, into coastal waters as a disposal method. The sewage pumping trucks often release the load directly into rivers or into sinkholes that recharge groundwater resources, rather than directly into the sea, as this is less visible and

often means a shorter trip. Likewise, many private homes in the Caribbean dispose of domestic sewage through “sumpholes”. In both instances, basically raw sewage is discharged directly into the karst or igneous geology without any regard for the potential to contaminate ground water and potentially coastal marine waters (DeGeorges, 1990a).

In the Caribbean, it has been clearly demonstrated that even secondary sewage treatment plants do not achieve designed treatment levels due to the difficulty in attracting skilled technicians to operate these plants, operational expenses and spare part supplies (Archer, 1988, UNECLAC, 1986 all *In:* DeGeorges, 1988a). Even if they functioned properly, secondary treatment plants do not adequately remove viruses (Table 8.4). While it takes ingestion of many bacteria to make a person ill, it takes the ingestion of only one viral unit to cause illness. In the U.S., where tourism is important, regardless of treatment, outfalls are generally designed to assure a minimum of about two to three days before any of the discharge returns to coastal waters in order to maximize the likelihood of viral die-off from the sun's ultraviolet rays.

Likewise, secondary treatment does not adequately remove the nutrients (nitrogen and phosphorus) that are ecologically damaging to coral reefs and grass beds (Table 8.4) (DeGeorges, 1990a) and (Table 8.5) (Bellairs Research Institute, 1989 *In:* DeGeorges, 1990a).

Table 8.4: Comparison of pollution removal by wastewater treatment and disposal options

Treatment Level -Effluent Concentrations				
Parameter	Raw Sewage (a)	Primary (b)	Secondary (a)	Tertiary (a)
Total Suspended Solids (TSS)	100-350 mg/l	35-123 mg/l	25-40 mg/l	5-16 mg/l
Biological Oxygen Demand (BOD)	100-300 mg/l	65-195 mg/l	25-35 mg/l	5-15 mg/l
Total Phosphorus as P	6-20 mg/l	10% Reduction(c) or less	8 mg/l (10% Reduction (b) to 30% Reduction(c))	0.5-8 mg/l 99% (b) Reduction
Total Nitrogen as N	20-85 mg/l	20% Reduction(c) or less	30 mg/l (d) (10% Reduction (b) to 50% Reduction(c))	3-30 mg/l (e) 90% (b) Reduction

NASA and other groups have experimented with artificial wetlands to achieve secondary treatment but this also requires sizeable land and a skilled technician to run the system and retain all of the above limitations with regard to effluent limitations. Nitrogen removal, primarily due to nitrification/denitrification, is 26-96% in aquatic plant treatment systems (natural wetlands), and 25-85% in

constructed (artificial) wetlands. Phosphorus removal in wetlands and aquatic plant treatment systems is not very effective because of limited contact between wastewater and the soil. National Space Technology Lab studies with water hyacinths achieved a 28-57% phosphorus removal. The principal mechanisms for phosphorus removal are plant uptake or retention in the soil (USEPA, 1988).

Tertiary treatment would be the solution if high tech were to be used in order to solve both ecological and public health problems in the tropical waters of the Caribbean. Even then, a long outfall would be desirable in order to maximize protection of the reefs and to minimize public health risks to bathers where tourism is an important sector of the economy. Unfortunately, this is very expensive, highly sophisticated and inappropriate technology for most of the developing world. If secondary treatment systems cannot be maintained then tertiary systems would pose that much more of a problem and expense. Sealy (2002) explains that even with tertiary treatment a long outfall may be necessary to achieve appropriate nutrient dilution necessary to protect coral reefs.

As a result, the nearshore discharge of effluent from sewage treatment plants throughout the Caribbean continues to pose both public health and ecological risks, both of these factors being vital to the sustainability of tourism.

It should be noted that the ecological risks are not only due to nutrient enrichment. If chlorination to kill bacteria/viruses is undertaken improperly, high residual chlorine levels in the effluent can be extremely toxic to aquatic life.

8.6.2 Montego Bay, Marine Park or Marine Cemetery? A Lesson for Africa

In the case of Montego Bay, there was a trickling filter plant built in 1966 to handle 0.75 million gallons of sewage per day (MGD). By 1988, four times this

amount of sewage was being sent to the plant, most of which was bypassing the latter, raw sewage being dumped into the mouth of the Montego River 200 m from the sea (DeGeorges, 1988a). Many hotels in Montego Bay were on package plants or septic systems. Since local drainage waters are naturally high in nitrogen (Woodley, *pers. comm.* In: DeGeorges, 1988a; Goreau & Thacker, 1994; Lapointe, 1997; Goreau, 2003a), the additional loading of phosphorus, often considered the limiting factor in algal production from improperly or untreated human sewage and wash (gray) water, can heavily eutrophy a system, resulting in heavy algal overgrowth on coral. In Montego Bay, most of the coral reef was dead. Goreau (1994) notes,

“coral reefs near Kingston were affected in the 1950s and 1960s, reefs near Montego Bay²⁰⁴ and Ocho Rios are thought to have been impacted in the 1970s, the area from Rio Bueno to Runaway Bay was affected in the 1980s, and Negril and parts of Western Jamaica were affected in the early 1990s (Goreau, 1992b In: Goreau, 1994). Algae overgrowth spread outward from source areas in expanding rings which were initially focused around local sources, but which have since begun to merge along much of the coastline. Along most of the south and north coasts eutrophication has become a persistent regional phenomenon. In addition nutrient inputs are causing permanent planktonic algae blooms, turning formerly clear blue waters dark, turbid, and green. At present only the least developed and populated areas have coral reef in good condition, with algae cover around 20% or less”.

The principal author made a series of recommendations to USAID, including the need for a long outfall as opposed to upgrading and/or renovating the existing sewage treatment plant and hooking in any hotels and restaurants on the bay into this system, as well as the need for working in soil conservation with the small-scale farmers degrading the watersheds of the two rivers entering the bay, the

²⁰⁴ Andrew Baynes (*pers. comm.*), First Class Diver, British Sub-Aqua Club and Head of El Salvador Branch in the 1970s would often recount his experience of diving Montego Bay to the principal author in the 1960's/early 1970s explaining that it was one of the best coral reefs/dive sites in the world.

Montego and Great Rivers, and the importance of establishing a water quality monitoring program.

These recommendations were made to USAID and The Nature Conservancy (TNC). A Nature Conservancy staff member²⁰⁵ was more than open to these ideas, but The Nature Conservancy management²⁰⁶ wanted to blame everything on the fishermen (“top-down” hypothesis – see Sections 8.3.1, Sea Urchin Dieback and 8.3.2, Over-Fishing of Algal Grazers), taking a typical preservationist approach to the idea of the marine park, which involves placing buoys around the reef defining the park and removing the fishermen. The management was oblivious to the real issues and/or had no interest in addressing them. With no biological data, the management claimed that the fishermen were over-fishing and over-harvesting algal grazing fish, resulting in the dead and dying reef, which The Nature Conservancy (TNC) staff had no idea existed until the principal author showed them his underwater slides. The principal author had the impression that management’s main goal was to finalize a grant with USAID and that what has been discussed above complicated the matter and possibly risked a simple straightforward contract having to be rewritten in order to address the real issues, and/or having to be dropped since possibly the costs of addressing the issues were beyond the budgetary limits of USAID.

As Goreau and Thacker (1994) explain with regards to degradation of Jamaican coral reefs,

“the fact that eutrophication has followed the course of coastal development and increasing resident and visitor populations, along with their releases of inadequately-treated sewage, suggests that excessive algae growth has been fertilized by increasing nutrient inputs rather than being due to destruction of corals by hurricanes,

²⁰⁵ Brian Houseal of The Nature Conservancy based out of the Washington, D.C. Headquarters

²⁰⁶ Dr. Gina Green based out of The Nature Conservancy Washington, D.C. Headquarters

which took place at the same time at all sites, or due to over-fishing, which had removed most of the top predatory fish and reached unsustainable catch/effort ratios more than 20 years ago (Aiken, 1991 *In: Goreau & Thacker, 1994*). It has been proposed that over-harvesting of algae-eating fish and epidemic die-off of algae-eating sea urchins has caused overgrowth of algae, and that only severe reductions in fishing can allow reef recovery. However, in recent years sea urchin populations have recovered towards pre-mortality levels in certain areas, but the algae have not vanished or the reefs recovered. Algae are also overgrowing deep fore reef sites where sea urchins were always rare compared to shallow back reef areas. In many parts of the island over-fishing of predatory fish has resulted in much more extensive domination of fish populations by algae-eating surgeonfish and damselfish, without evidence of algae reduction. Recovery of sea urchin eating triggerfish populations would be predicted to reduce sea urchins and increase algae if the over-fishing hypothesis was correct, but reef eutrophication was absent when triggerfish were still common. Algae abundance appears to be primarily controlled by available nutrients rather than by herbivory. While there is no doubt that over-fishing has dramatically reduced fish sizes and species diversity, there is little reason to believe that reductions in fishing alone would have any significant impact on algae overgrowth unless nutrient sources are reduced”.

Goreau goes on to say,

“In the last few years there has been a flood of papers blaming algae on lack of herbivores due to over-fishing, done by people who know how to count fish and sea urchins but not how to measure nutrients. Brian Lapointe and I measured nutrients and the physiological response to them, and in fact Jamaican reefs, far from lacking herbivores, now have nothing but herbivores, as algae is the only food left, due to the excessive nutrients. In 1996 we found it impossible to find sites in Jamaica below the critical limits (of nutrients) except in the rough and windward east. The result of all this bad science is worse policy: the herbivore people blame the fishermen, who are in fact the victim of everybody else's pollution (see Section 8.3.3, Caribbean Fishermen Victims or Culprits – Lessons for Africa). Barbados is very high in nutrients too, but oddly enough there are few macroalgae, only a dense, low, rapidly

growing algal turf, that is heavily chomped on by the huge parrotfish, which Bajans don't eat" (Goreau, 2004c).

The USAID personal services contractor²⁰⁷ managing The Nature Conservancy (TNC) project as well as nearby small-scale farmer watershed/soil conservation management projects told the principal author that it was too complicated, bureaucratically, to include the Montego and Great Rivers that discharge into Montego Bay in the existing USAID soil conservation/watershed programs. After the principal author had showed the USAID personal services contractor and The Nature Conservancy (TNC) underwater slides, the personal services contractor asked if he could borrow them to make copies, but conveniently lost the slides that showed what a disaster area the reef was in this marine park. Often bureaucrats and NGOs/contractors conspire, no different than dam builders and governments, since at the end of the day for most it is about money, power security and last but least - addressing real issues or empowering local people to sustainably manage their resources, much so-called development and conservation in the tropics being unsustainable. It was evident to the principal author that when he left Jamaica, 99% of his recommendations would be ignored, as was the case in most of the advisory roles he had with the U.S. government in both the Caribbean and Sub-Saharan Africa.

8.6.3 Sewage Treatment throughout the Caribbean

The principal author has assessed the inadequacy of treatment throughout much of the Caribbean (Table 8.6) (DeGeorges, 1990a). The degraded coral reef noted in this table is very likely due to a number of causes, not just from inappropriate sewage technology, but definitely related to land-based pollution (e.g. sedimentation, pesticide and fertilizer runoff from agriculture).

²⁰⁷ Mark Nolan

Table 8.6: Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
BARBADOS		
-Bridgetown	-Activated sludge	-Major odor problems, short outfall degrading surrounding environment.
-West and South Coast (major tourism areas)	-Hotels on septic systems or package plants with short outfalls -Note: Deepwater outfall planned for Bridgetown and West Coast	-Fringing reefs 99% dead, outer bank reefs beginning to show signs of algal overgrowth, nearshore fishing on a decline, beach erosion accelerating. -Reef mostly dead from inappropriate sewage and apparently high sedimentation associated with steep-sloped agriculture.
		-“Barbados reefs are eutrophic, but because there is high parrotfish grazing the algae are made of short turfs rather than fleshy macrophytes, but the dead coral is still algae covered” (Goreau, 2005).
GRENADA		
-St. Georges	-Raw sewage outfall.	-Did not dive area, but outfall appeared too short in relation to currents, risking to contaminate nearshore waters (see Table 8.7) – 400 meters outfall – real question is degree of offshore currents in region of outfall to dilute and carry pollution out to sea
-Grand Anse Bay	-Three tourist hotels on septic systems, Medical school on septic system. Private homes?	-High incidence of eye, ear and skin infections & High percentage of the <i>Porites sp.</i> coral dead and overgrown with <i>Dictyota sp.</i> algae

Table 8.6 (Cont.): Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
<u>TOBAGO KEYS, THE GRENADINES:</u>	-Up to 140 boats a day anchor in the vicinity of these reefs during the winter months, none of which have holding tanks.	-Approximately 99% of the elkhorn coral (<i>Acropora palmata</i>) dead but still standing
<u>Horseshoe and World's End Reefs</u>	-Additional pollution is believed to come from inappropriate sewage disposal on the islands of Petite St. Vincent, Petite Martinique, Union, Mayreau, Canouan and Palm.	-Approximately 30-40% of <i>Porites</i> sp. Dead -Overall state of reef degraded, much of dead coral covered in light purple coralline algae
<u>ST VINCENT</u>		
<u>Young Island and the Bay lying between Young Island and Dike Island</u>	-Hotels on septic systems -Large number of sail boats with no holding tanks	-Coral reef around Young Island and mainland hotels mostly dead -Large areas of dead elkhorn and <i>Porites</i> sp. Elkhorn alive in the early 1980s
<u>Kingstown</u>	Central collection system pumping raw sewage into Kingstown Harbor	----- Between Harbor and Camden Industrial Park: -Old Woman Point. Shallow star coral shows signs of bleaching. Deeper portions of reef - star and other coral in reasonable condition -Turtle Bay most of reef algal covered -Coral Garden near industrial park, mostly dead algal-covered <i>Porites</i> sp. -Questelles Point just north of industrial park, most of coral appears healthy, lots of deep water star coral, <i>Montastre annularis</i>

Table 8.6 (Cont.): Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
ST. LUCIA Castries	-Sewage collection, preliminary treatment dumped into harbor	-Water quality and marine benthos study by Caribbean Health Institute showed area to be very eutrophic.
Anse Chastinet, Pitons Area	-Hotel on septic system -Town? Septic systems	-Some of best reef in the Windward Islands. -Watershed a protected rainforest – low human population
DOMINICA		
Roseau	-Up to ten raw sewage outfalls	-Dangleben's Reef. Shallower than 30 feet coral smothered in <i>Dictyota sp.</i> algae. Below 40 feet depth, algae cover falls off and living coral becomes more dominant.
Small Coastal Villages	-Community pit latrines right on the edge of the sea	
Other	-Many people dump chamber pots into streams.	-La Bim wall covered in silt -Hot Springs area covered in <i>Dictyota sp.</i> Algae -Scottshead area some good reef, but heavily algal covered -Point Des Fou reef walls nice but coral heavily covered in algae

Table 8.6 (Cont.): Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
<u>ANTIGUA</u>	Becoming heavily built out for tourism, hotels on septic systems or package plants.	<ul style="list-style-type: none"> -British Armed Forces divers as part of Reef Watch warn Antigua government that its reefs are rapidly degrading from sewage and sedimentation. -Shallow offshore reefs on high-energy zone at Ariadne Shoals and Soft Willie appear degraded.
<hr/>		
<u>ST. KITTS</u>		
Basseterre	-No sewage or collection system, sewage flushed into Basseterre Harbor during rain events	-USAID sponsored Southeast Peninsula environmental study found that most of the reefs south of Basseterre were degraded and algal covered.
Sugar Cane Refinery	-Dumps untreated waste into Basseterre Harbor	
Frigate Bay Hotels	-Package treatment plants into lagoons, one discharging into Atlantic and the other to the Caribbean side, newer hotels treatment discharge unknown	
<u>U.S. VIRGIN ISLANDS</u>	Secondary treatment and septic systems?	Personal communication between the author and natural resources planner from islands associated with Ed Towle of Island Resources Foundation, leads the author to believe that there is heavy coral reef degradation.

Table 8.6 (Cont.): Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
<u>HAITI</u>		
Port Au Prince	No known treatment systems! Raw sewage direct or through groundwater seepage	Les Arcadins Marine Park contains severely degraded coral smothered by <i>Dictyota</i> sp. algae.
<u>DOMINICAN REPUBLIC</u>	Unknown	Coral reef appears healthy.
<u>HAITI</u>		
Port Au Prince	No known treatment systems! Raw sewage direct or through groundwater seepage	Les Arcadins Marine Park contains severely degraded coral smothered by <i>Dictyota</i> sp. algae.
<u>JAMAICA</u>		
<u>Montego Bay</u>	-Trickling filter plant is being bypassed dumping 3.0 million gallons/day of raw sewage into Montego River 200 meters upstream from where it enters Montego Bay	Coral reef over the entire bay is mostly dead and algal/silt covered.
<u>Note: Deepwater outfall planned?</u>	-Some hotels on septic systems and package plants -Two major rivers with small-scale farmers using inappropriate soil conservation resulting in heavy siltation	

Table 8.6 (Cont.): Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)

LOCATION	SEWAGE TREATMENT LEVEL	OBSERVED ECOLOGICAL IMPACTS
BELIZE		
<u>Belize City</u>	-Oxidation ponds with nearshore outfall	-Coral reefs dived by author along Belize's 240-250 km barrier reef appear to be highly degraded and have high algal cover.
<u>Ambergris Cay, Holchan Marine Park</u>	-Septic tanks at most hotels	
<u>Caye Caulker</u>	Four inch raw sewage outfalls	-This includes the outer atolls such as Lighthouse and Blue Hole, though they are less degraded than the barrier reef along two Cayes.
<u>Placencia</u>	-Fishing village, maybe one resort ?	
<u>Lighthouse Reef and Blue Hole</u>	-No sewage, Virtually undeveloped	-Obvious other factors coming into play, but sewage believed to be major cause of degradation.
Observed Ecological Impacts (cont.):	Observed Ecological Impacts (cont.)	
-Other possible causes linked to land-based pollution, noted by local fishermen are rivers & streams that now run dirty from watershed degradation linked to U.S. citrus companies, and refugees practicing slash and burn agriculture in Belize. Fishermen also claim that "dirty" water from the deforested Gulf of Honduras flows over the reef during the rainy season.	-Cay Caulker (cont.): In the shallow backwater areas, boulder coral (mountainous star coral) alive along the edges but smothered with algae on the top similar to Mexican Rock at Ambergris Cay. -Fishermen claim that in the late 1970s a hurricane hit and a fertilizer ship ran aground on Lighthouse Reef. Fertilizer never removed, and a freak red tide killed off many of the fish that are algal grazers, especially parrotfish whose populations have never recovered. These events could be linked and need further investigation.	-In vicinity of Ambergris Cay and Cay Caulker, annual production of sewage equivalent of dumping 6,500 fifty pound sacks of 20/10/10 (N/P/K) fertilizer onto barrier reef. -Cay Caulker: structurally intact dead elkhorn corals, <i>Acropora palmata</i> , at the very top of the barrier reef. In the cut, large areas of massive leaf coral, <i>Agaricia agaricites var. danai</i> , smothered in algae. Dead elkhorn coral covered in coralline algae also seen intact at depths of 15 feet.

Source: DeGeorges (1990a)

However, where quantitative data exists, coral reef degradation has been closely linked to inappropriate sewage disposal (Tomascik & Sander, 1985; Hunte, 1987; Bellairs Research Institute, 1989; Tomascik & Sander, 1987a; 1987b all *In:* DeGeorges, 1990a; Goreau, 2003a; Lapointe, 2004b; Lapointe, *et al.*, 2004).

Goreau (2005) notes that “death of the elkhorn (coral) in the Eastern Caribbean was due to ‘White Band’ disease around 1979” (see Section 8.10.2, Coral Diseases). If there are high nutrient discharges in the area, this dead coral will tend to have high algal cover.

Sealy (2002) presents additional information on current sewage treatment, which reflects steps being taken by the governments of Barbados and Grenada to protect coral reefs while the principal author was in the Caribbean (Table 8.7).

“The majority of the countries have achieved less than 20% sewerage coverage of their populations. Most of the population on these islands resides on the coast resulting in significant loading of nearshore waters with nutrient and bacteria rich wastewater” (Sealy, 2002).

Table 8.7: Overview of domestic wastewater systems in selected Caribbean countries, 2002

Country	Size of Population	% Sewered	Level of Treatment		Method of Disposal		Length of Outfall (m)	Depth of Discharge (m)	
Bahamas	300,000	< 15	Secondary		Deep well injection		0	130	
Barbados	268,000	a) 3	a) Secondary (Bridgetown)		a) Marine outfall	300	a) 13

8.6.4 The Solution to Pollution is Dilution for Human Waste Disposal in the Caribbean and Most Tropical Waters, Lessons for Africa

USAID spent 1988-1990 working with the Bellairs Research Institute, which is associated with the University of the West Indies and McGill University, Canada. Using local Caribbean ecologists, sanitary engineers and oceanographers, it was determined that in most cases, the old adage “**the solution to pollution is dilution**” holds true for the tropical areas of the world. The pollution problem, both in terms of public health and ecology, is a nearshore coastal phenomenon. Modern-day technology solves neither of these issues without resorting to extreme expense and sophistication, neither of which is appropriate to the developing world.

It has been determined that in most cases in the Caribbean, the solution to wastewater treatment and disposal is preliminary treatment with a long outfall which will go beyond the coral reefs into the open ocean and be quickly diluted out by offshore currents. This is the solution being chosen by both Barbados and Grand Anse in Grenada. The first reaction of many ecologists from the northern hemisphere will be that this is unsound.

First of all, this is a nearshore problem. Secondly, if one takes all of the Windward and Leeward Islands, there are only about 700,000 residents (in 1990) plus temporary tourists, not even the size of a large metropolitan area in the United States or Europe which may contain 10 million or more residents plus significant quantities of industrial wastes. In the Caribbean, with few exceptions (e.g. rum distilleries and sugar cane refineries), most sewage is human and contains only conventional pollutants (organic matter, suspended solids, nutrients and bacteria/viruses). Furthermore, the Caribbean Sea is vast relative to the amount of human pollution. It is not a closed system with a long detention time

(e.g. Chesapeake Bay, Great Lakes and Mediterranean Sea) or of limited carrying capacity to absorb such pollutants, as with many rivers.

The solution for Grand Anse, Grenada consists of a collection system for both domestic sewage and gray water (wash water), preliminary treatment to remove grease, grit and large particulate matter (25-75 mm screens producing 100 kg dry weight of solids per day under maximum operation), followed by a 350-meter (1,148 foot) outfall with a 100/1 diffuser off Point Salines (Table 8.7). The length of the outfall was determined by conducting long-term oceanographic current studies to locate the best site in the area that has the strongest offshore currents on a year-round basis. This was combined with water quality modeling to determine at what point beyond discharge that nutrient and other water quality concentrations would be returned to background levels, which was about 200 m from the discharge point.

Finally, it comes down to economics, that is land costs (a premium on islands), construction costs, operation and maintenance costs including collection and disposal of sludge, which can become a solid waste problem and finally the cost of a highly skilled technician to run the facility. A comparison of these factors for the 600,000 gpd (gallon per day) (0.6 MGD) facility being planned for Grand Anse Beach, Grenada is contained in Table 8.5. Using design criteria of 170-227 liters/day/person (45-60 gpd/person) of sewage, this system in theory could serve between 10,000-13,300 people. In this case, construction costs of secondary treatment alone are from three to five times the cost of preliminary treatment and do not solve the ecological or public health problems without an extended outfall (Tables 8.4 and 8.5).

Off Barbados, there were

“exhaustive studies (which showed) that an outfall positioned outside of the bank reefs (for South Coast sewage) would take advantage of strong offshore currents and would have minimal impact on marine ecosystems. The project was designed and constructed to take advantage of the assimilative capacity of the ocean. The LBSMP (Land-Based Sources of Marine Pollution Protocol) does not appear to take into account the natural carrying capacity of the Caribbean Sea” (Sealy, 2002) although it should.

Such decisions must be made on a case by case basis taking into account the amount of sewage produced, background water quality, degree and drop off of littoral zone, oceanographic conditions and distance between impact areas (e.g., islands and coral reefs) versus dilution to background levels.

8.6.5 Other Sewage Treatment Options

Although land disposal (e.g., spray irrigation and deep well injection – 100s of feet into the ground below impervious layers or a high density aquifer which will trap wastewater) should be considered as an option, this normally requires at least secondary treatment, and sophisticated technology and timing (e.g., effluent from spray irrigation usually sprayed at night in order to minimize the risk of viral aerosols contaminating humans). Operation and maintenance thus return as a problem, although this could be resolved if the hotelier or ideally a group of hoteliers and/or a city were willing to pay the cost of a highly skilled technician to maintain the system. However, in general this has not proven successful in the tropics. It appears that often more effluent is produced than needed for irrigation (DeGeorges, 1990a).

A long outfall with minimal treatment may not be the best solution off of Belize, with its shallow continental shelf and extensive reef network, though this would

need to be studied. There is a risk that if many of the barrier reef islands are developed with offshore outfalls, there may be some potential to contaminate reefs on the outer atolls such as Turneffe, Lighthouse and Grovers Reef. Oceanographic studies of currents and modeling of the discharges, possibly with a 20-50 year planning horizon could provide estimates of such risks.

In all cases, water quality (nutrient levels) and reef monitoring (e.g., percentage live/dead coral & percentage algal cover) are critical once a solution/technology has been selected and implemented.

8.6.5.1 Deep well injection, Key West, Florida – failure of a high tech solution

Massive algal blooms smothered coral reefs around Key West, Florida, in the 1980s and 1990s. The cause was clearly identified as being from the sewage outfall (USEPA, 1999 *In:* Goreau, 2003a). A grass roots campaign led by the local Reef Relief NGO succeeded in forcing government authorities to build an advanced wastewater treatment system (Quirolo, 2002 *In:* Goreau, 2003a) with deep well injection into the ground beyond where it could contaminate groundwater and eventually nearshore waters. In the last few years, the epiphytic algal forests that had killed almost all the corals in nearby reefs such as Eastern Dry Rocks have died back and the coral is now starting to recolonize the clean bottom (Goreau, 2003a). However, Goreau (2003a) worries that deep well injection simply causes sewage to flow underground and re-emerge elsewhere. Widely used in Florida, instead of solving the problem they are killing the reefs where the water re-emerges at sea (Bacchus, 2002 *In:* Goreau, 2003a).

The question is how deep does the sewage need to be injected so that it cannot possibly resurface to contaminate nearshore waters? Engineering firms can sample and model these requirements in the design of such systems. A key

concern here would be the costs involved in constructing and operating such a system in poor developing countries, making the appropriateness of such systems very questionable.

8.6.5.2 Inland aquifer discharge, Caribbean

On islands like the Bahamas, Barbados and Antigua with limestone (karst) geology, a shallow inland discharge will eventually reach the coast via a groundwater flux to the nearshore, similar to effluent from septic tanks. Pollutant transport modeling in Barbados for the West Coast Sewerage Project indicated that inland aquifer recharge using secondary treated sewage via absorption wells would eventually result in significant loading of nitrogen at the coastline. It was concluded that nutrient removal would be necessary even for inland disposal (Sealy, 2002).

8.6.5.3 Land discharge of sewage

Goreau (2003a) recommends this. However, land-based discharge normally requires secondary treatment prior to use (USEPA, 1976; DeGeorges, 1990a). Once treated, the wastewater effluent can be discharged on land (USEPA, 1976):

- For irrigation through sprinkler systems which removes 98% of the BOD, 80% of the COD, 98% of the suspended solids, 80% of nitrogen, 95% of phosphorus, 95 % of metals and 98% of micro-organisms by the soil/plant system;
- Through overland flow where secondary effluent is sprayed over the upper edge of a sloping terrace flowing slowly downhill through grass and vegetative cover. Clay and clay loam soils are best with results for removal from secondary treated effluent of 92% of the BOD, 92% of

the suspended solids, 70-90% of nitrogen, 40-80% of phosphorus and 50% of metals; and/or

- Infiltration-inflow to recharge groundwater through percolation on spreading basins resulting in the removal of 85-99% of the BOD, 98% of the suspended solids, 0-50% of nitrogen, 60-95% of phosphorus and 50-95% of the metals (insignificant nutrient removal – may not be appropriate).

The advantages are that an advanced degree of waste treatment is attained, the wastewater and nutrients are used productively, and little or nothing should return to the nearshore waters. Once again, the limiting factor may be the ability of a developing country to maintain and operate a secondary treatment system, the history of which is poor. There are also a number of potentially limiting factors with regard to irrigation and land treatment of effluent that must be addressed.

Storage Ponds

Even in the tropics, storage ponds may be necessary during the rainy season when land disposal may not be possible. To obtain a high degree of nitrogen removal, that effluent should be applied to land only during the season of active crop growth (USEPA, 1976) – which in the tropics could be most of the year, though this application is limited during the rainy season (four to five months). Storage lagoons able to hold effluent during the non-productive period and/or the rainy season when the soil would be saturated with water would be required.

Land Availability for Irrigation

A sizeable land area is required, which many tropical islands do not have but which continents may have. USEPA (1976) provides two examples, one of a 15

MGD secondary effluent irrigating 2,300 acres (958 ha) of crops (wheat, barley, oats, rye, sorghum and cotton) and the other of 43.4 MGD of secondary effluent irrigating 6,300 acres (2,625 ha) of a 10,000 acre farm to grow corn. However, in the latter example, samples collected in under-drains still contained 0.05 mg/l phosphorus and 3.2 mg/l nitrogen. These examples amount to about 60-64 ha/MGD of secondary effluent. Similar land areas would likely be needed for the other land disposal systems of from 100-600 acres (41-243 ha)/MGD of effluent (USEPA, 1976).

Heavy Metal Contamination of Crops from Effluent Irrigation

Certain crops can concentrate heavy metals, which could cause plant toxicity problems (e.g. copper and zinc if municipal and industrial sewage are mixed, and from boron linked to detergents in municipal sewage) (USEPA, 1972).

Viral, Bacterial and Parasitic Contamination of Crops and People from Effluent Irrigation

Primary (preliminary) treated sewage should not be used to irrigate crops for human consumption. The USEPA advises that only crops that are to be used for canning or similar processes be irrigated with secondarily treated effluent – which implies no irrigation with secondary effluent of fresh produce (USEPA, 1972).

Helminth (e.g., ascariasis, fascioliasis, cysticercosis and tapeworm) ova and parasitic worms as well as *Schistosomiasis* have been known to survive sewage treatment processes and chlorination, although epidemics traced to crop contamination have not been shown linked to irrigation with treated effluents. The use of furrow and sub-irrigation can further reduce the risk of worker and/or crop contamination (USEPA, 1972).

Viruses can survive chlorinated secondarily treated effluent. If sprinkler irrigation is used, this could contaminate crops and workers. Likewise, it would not be wise to use such effluent on golf courses where clients could be contaminated (USEPA, 1972); though spraying at night might be considered.

Nutrient Removal from Irrigation and Other Land Disposal Methods

The amount of wastewater that can be applied is determined by balancing the nutrient load of wastewater against the nutrient removal capacity of the soil (USEPA, 1972) and vegetation. The soil tends to have a tremendous ability to remove phosphorus so that this should not limit irrigation with effluent. The nitrogen load needs to be balanced against crop removal (USEPA, 1972), the main means of removing nitrogen (USEPA, 1976).

If the vegetation grown is for livestock feed, care must be given that nitrate does not accumulate in the stems and leaves to toxic levels (USEPA, 1972). In areas with karst geology, surrounding groundwater and nearshore waters would likely need careful monitoring to make sure that nutrient contamination does not occur – though monitoring should be a part of any system to assure its effectiveness.

Thus, land discharge of sewage, for any number of reasons, does not appear appropriate unless this is on East Africa's mainland and pumped well inland from the coast possibly for agricultural irrigation. The coastal zone is being planned for development south of Maputo between Mozambique and South Africa in the vicinity of the Maputo Elephant Reserve. As an alternative to coastal discharges, this area has extensive wetlands that could possibly be part of a secondary treatment/overland flow system, with the already nutrient rich wetlands polishing the final effluent. This would require modeling and monitoring to insure the

integrity of the wetlands. On small islands, land, among other issues, would be a major limiting factor.

8.6.6 Examples of Land-Based Treatment and Discharge of Sewage

8.5.6.1 Land-based treatment, Palawan, Philippines, lessons for Africa

The El Nido resorts on islands off the northwest coast of Palawan, Philippines, have standard secondary sewage treatment plants whose effluent is used to water the resort plants and inland forests. Reefs directly offshore from where the sewage effluents are applied show no more algae near than away from the site, because all the nutrients are being absorbed by the land vegetation (Goreau, Goreau, & Cervino, 1997 *In:* Goreau 2003a).

8.6.6.2 Land-based treatment, Akumal, Mexico, lessons for Africa

The diving resort town of Akumal in Mexico has all of the hotels in town on advanced wastewater gardens designed by Mark Nelson, Gonzalo Arcila and associates to absorb all their nutrients as a means of protecting the coral reefs. The strategy is failing because the entire coastline is under uncontrolled development without appropriate sewage treatment, so the Akumal reefs are being over-grown with algae fertilized by nutrients from surrounding development. This points out the need to have treatment of all sources affecting the reefs, not just some of them (Goreau, 2003a).

8.6.6.3 Failed attempts at land-based treatment, Negril, Jamaica

Negril, at the western tip of Jamaica, has the largest beach on the island. Because of a large swamp next to it, it was completely undeveloped since it was

unreachable by land until 1960 when roads were put in and the swamp drained. With tourism slowly developing by the mid-1980s, the epiphytic algae was confined to the mouths of two canals draining the swamps, where they were sharply zoned by species in concentric rings around the point sources of nutrients (Goreau, 2003a).

In the next five years, the tourism expanded to cover the entire beach and the algae began to kill corals across the entire bay. The local divers, the Negril Coral Reef Preservation Society, and later the Negril Environmental Protection Trust, alarmed at the sudden and rapid decline of the reefs, asked Goreau²⁰⁸ to be their advisor to document the algae problem (Goreau, 1992c *In:* Goreau, 2003a). The European Union (EU) offered to fund a sewage treatment plant (Jelier & Roberts, 1992 *In:* Goreau, 2003a). The local NGOs insisted that sewage from the entire watershed needed to be collected and since secondary sewage treatment did not remove nutrients, asked that biological tertiary treatment be included (Goreau, 1993 *In:* Goreau, 2003a), which the EU refused. The sewage collection system only collected the sewage from the hotels and villas along the shore, but excluded the hill villages and slums where the vast majority of the population lived. As a result, the vast bulk of sewage in the watershed was not collected by the sewage plant.

The sewage plant design consultants refused to include tertiary treatment, on the (incorrect) grounds that this was too complicated and expensive for a small island developing state, and was not needed anyway. The claim that tertiary treatment was too complicated and expensive was based on expensive temperate climate systems, highly prone to failure when used to remove nutrients by chemical and microbiological means (Goreau, 2003a).

²⁰⁸ Dr. Thomas J. Goreau President Global Coral Reef Alliance, 37 Pleasant Street, Cambridge, Massachusetts 02139, USA, Telephone: 617-864-4226, 617-864-0433, E-mail: goreau@bestweb.net, Web site: <http://www.globalcoral.org>

The history of maintaining secondary (e.g., Montego Bay Trickling Filter Plant, hotel package plants) let alone tertiary treatment is well known all over the Caribbean. It is possible that land-based treatment of secondarily treated effluent would have worked, which is what Goreau advocated (Goreau, 2005) – but there is a question of linking in all residents of the watershed to the sewage system and the size of land needed to irrigate/dispose of the effluent. Furthermore, on this side of the island, as with Montego Bay, the littoral zone is very narrow and depending on the currents, one could run an offshore outfall with preliminary treatment or a deepwater outfall modeled to assure that the likelihood of sewage and associated nutrients returning to the coast would be small. This is being used off of Barbados and Grenada. Barbados probably has done more to assess appropriate sewage disposal technology for small islands and the tropical coastal zones than anywhere else in the world. Exhaustive studies in Barbados demonstrated that an advanced preliminary plant with a long outfall was shown to be the least cost alternative, which would protect coral reefs and other nearshore environments, as well as address public health problems. It was shown in relatively exhaustive studies that an outfall positioned outside of the bank reefs would take advantage of strong offshore currents and would have minimal impact on marine ecosystems. The project was designed and constructed to take advantage of the assimilative capacity of the ocean (Sealy, 2002) and it is this low maintenance low cost option that Goreau seems to ignore.

Regardless, the refusal to sewer all residents meant that Negril's coral reefs would be a write-off (Lapointe & Thacker, 2002 *In:* Goreau, 2003a), succumbing to epiphytic algae similar to the principal author's assessment of Montego Bay. Water quality studies conducted in every reef, mangrove, river, wetland, spring and groundwater body in the entire western Jamaica watershed indicated that over 99% of all sites were already above the nutrient eutrophication limits (Goreau &

Goreau, 1997 *In:* Goreau, 2003a). After the sewage treatment plant went in, the nutrients continued to increase (Lapointe & Thacker, 2002 *In:* Goreau, 2003a) and the algae continued to kill the corals (Porter, Porter, Porter, Thacker, Nlack, Gabbidon, Getten, Quirolo, Marcinek, & Dustan, 2002, *In:* Goreau, 2003a).

The lesson here, as with Montego Bay, is that even when the problem is understood, it is useless if those who control money and policy refuse to act responsibly. Ironically, despite its failure, this effort to manage the nutrients of an entire coastal zone and watershed as a single unit (Goreau, Daley, Ciappara, Brown, Bourke & Thacker, 1997 *In:* Goreau, 2003a) led directly to USAID's "ridge to reef" program and to the UN "hilltop to ocean (H₂O)" programs. However, Goreau (2003a) feels that these programs

"will be doomed to failure if they simply continue to pursue cosmetic projects that are not broad enough to eliminate ALL of the nutrient inputs to the coastal zone from the adjacent watersheds. Much more serious and comprehensive approaches are needed to restore the health of coral reefs, especially in small islands that are so critically dependent on their marine resources".

These are similar conclusions to those of the principal author in the case study on Montego Bay (Section, 8.6.2, Montego Bay, Marine Park or Marine Cemetery? A Lesson for Africa).

8.6.7 Possible Solutions for Sewage Discharge from Tourism Development and Cities of East Africa

The major reef systems off East Africa include

"the complex barrier and island reef systems of northern and southern Tanzania (800 km long) and northern Mozambique (800

km); the narrow fringing reefs of southern Kenya (200 km); smaller isolated reefs along the southern Mozambique coast (500 km) to South Africa (150 km); and patchy reefs in northern Kenya and southern Somalia (500 km)" (Obura, Church, Daniels, Kalombo, Schleyer & Suleiman 2004 *In: Wilkinson, 2004*).

Since much of East Africa has a narrow littoral zone, the depth dropping off very quickly, preliminary treatment with a long outfall, the location based on proper oceanographic studies, may be a very cost-effective solution. This may be able to serve many hotels and/or cities with one outfall or at least minimal outfalls depending on the size of the city and/or population being served.

A low-cost option that should be strongly considered for the Cays of Belize and much of the coastal zone along East Africa and the islands of the southwestern Indian Ocean is to remain on septic tanks, but keep the tourism low volume exclusive high-paying within the assimilative capacity of the environment to absorb the pollution. A careful study would need to be undertaken of soils, percolation rates, height of the groundwater table after rains (a high groundwater table after rains could cause septic tank malfunctioning and direct discharge of sewage into coastal waters) and the dilutional capacity of the surrounding coastal zone. This may require the use of a sanitary engineers, soil scientists, groundwater specialists and ecologists, with the installation of appropriate mounded septic systems developed for coastal areas with high water tables, situated well inland, along with a long-term water quality and reef-monitoring program – all a part of the cost of doing business if long-term sustainability is desired. People are looking to escape from the polluted rat race of the Western urban cities and should be willing to pay for such environmentally conserving programs through higher user fees and the chance to dive on pristine coral reefs.

If low tourist volume septic systems and/or higher tourist volume preliminary treatment with a long-outfall fail to solve the problem of nutrient pollution and

high algal cover, it may be due to additional pollution from a degraded watershed and/or regional pollution as seen off of Belize (see Section 8.5.1.3, Increase in land-based pollution from within Belize's frontier and Section 8.5.1.4, Possible increase in land-based pollution from outside Belize's frontier). Once again, protection of coral reefs, at a minimum, will require a watershed approach and in many cases a regional approach.

The higher technical solutions mentioned above are available, but are costly to build and would require a highly paid technician to run and operate them, even in the case of preliminary treatment with a long ocean outfall.

Africa does not need built-out areas as on many islands in the Caribbean. Low volume exclusive tourism may be Africa's and the southwestern Indian Ocean's niche in the global coastal tourism market. Florida and the Caribbean are for the most part over-developed, their marine ecosystems are highly degraded, and thus they could never compete with areas that are developed to maintain pristine nearshore conditions.

However, Goreau (2005) states,

"very few places have done so (Maldives, The Seychelles, Mauritius, Nevis, some of the Grenadines) but they have not avoided local pollution (especially Mauritius lagoons). Almost everywhere else, when the first hotels (usually set up by foreigners) are seen to make money all the locals rush to copy them, and the result is an unplanned slum with out of control pollution".

This comes down to educating decision-makers and then political will in overcoming short-term goals of stimulating the economy versus maintaining the long-term ecological and economic integrity of the area. Unfortunately, today,

short-term decision-making appears to be the trend on land (e.g., wildlife & timber) and by the sea!

8.7 KEY SPECIES OF EPIPHYTIC ALGAE ASSOCIATED WITH LAND-BASED NUTRIENT POLLUTION

Goreau (2003a) notes, “the role of nutrient gradients in controlling algae abundance and species composition has generally failed to be recognized by marine biologists...algae show more clearly zoned patterns along gradients than any other group of coral reef organisms, and so are the best bio-indicators of coral reef health of all except for live coral cover. Unfortunately the information needed to interpret them has never been published, and it is of the greatest importance to do so, in order to allow the great amount of information to be gained from their study to be more widely applied”.

Goreau (2003a) feels that

“algae distributions are in fact a better indicator of nutrient inputs than the nutrient concentrations themselves. The reason for this is that nutrients vary very quickly in space and time as the pattern of water movement shifts with currents, tides, winds, and waves, and because they can be rapidly taken up by algae. If seriously eutrophic waters remain over a reef for long enough, algae will remove most or all of the nutrients. As a result a eutrophic reef can have low measurable nutrients in the water, because they have been taken up and are part of the algae biomass, to be released again when the algae dies and decomposes”.

From personal observations by the principal author in the Caribbean, the most susceptible corals to algal overgrowth are the staghorn (*Acropora cervicornis*), the elkhorn coral (*Acropora palmata*) and finger coral (*Porites* spp.).

“*Acropora palmata* (elkhorn coral), *A. cervicornis* (staghorn coral) and *A. prolifera* (fused-staghorn coral) were the dominant reef-

building corals on reefs of Florida and throughout the Caribbean for the past half-million building years. These species have suffered an 80 – 98% decline over the last 30 years throughout vast portions of their range, causing major losses in coral cover...The Center for Biological Diversity in San Francisco, filed a petition with the USA government in March 2004 requesting that these species be protected under the federal Endangered Species Act (ESA)" (Wilkinson, 2004).

As is discussed below, many of these *Acropora* spp. corals died from "White Band" disease (see Section 8.10.2, Coral Diseases). In this case, algal-over-growth may have been a secondary impact on an already dead or dying coral linked to pollution.

The least susceptible are the gorgonians (*Gorgonia* spp.) and fire coral (*Millepora* spp.). Eventually, all of the hard corals and the gorgonian fan corals (e.g. *Gorgonia ventalina* and *G. flabellum*) begin to succumb to this phenomenon as the nutrient pollution progresses. Where the principal author has observed this as a problem, the most common genera of benthic (epiphytic) macroalgae that turn coral reefs into algal reefs include (DeGeorges, 1990a):

- Turbinaria* sp., a brown algae, family Cystoseiraceae
- Lobophora variegata*, a brown algae, family Dictyotaceae
- Dictyota* spp., a brown algae, family Dictyotaceae
- Halimeda* spp., a green algae, family Halimedaceae
- Amphiroa* sp., a red algae, family Corallinaceae

Wilkinson (2002) notes that large increases in macroalgae, mainly *Lobophora* sp. and *Dictyota* sp. on Caribbean coral reefs, prevent the recruitment and settlement of coral larvae. Although there is limited quantitative data, these are common algae found on the coral reef, which in nutrient enriched conditions appear to take up this new human-induced niche, out competing corals for space. Similar

assessments are needed off of Africa. The principal author noted the brown algae *Turbinaria* sp. and *Sargassum* sp. as apparent nutrient pollution indicators off of Mahé and St. Anne Marine Park, the Seychelles (DeGeorges, 1990b). Off Sri Lanka, Rajasuriya (2002 *In:* Linden, Souter, Wilhelmsson & Obura, 2002) found that overgrowth by *Halimeda* spp., various filamentous algae and sedimentation appear to inhibit recruitment and growth of corals.

Goreau (2004d; 2005) believes that the above epiphytic algae observed by the principal author are largely characteristic of low (*Turbinaria* sp., *Amphiroa* sp., *Halimeda* sp.) to moderate (*Dictyota* spp., *Lobophora* sp.) nutrient pollution, but they are among the first to increase strongly as nutrient inputs increase. They are then replaced by other species as nutrients become higher. These replacement algae identified by Lapointe, *et al.* (2004) and Goreau (2004d) as a result of land-based nutrient pollution include:

Dictyosphaeria cavernosa, a green algae, family Valoniaceae

Ulva fasciata, green algae, family Ulvaceae

Digenea simplex, red algae, family Rhodomelaceae

Laurencia intricata, red algae, family Rhodomelaceae

Goreau (2004d) explains that the top two algae on this list are indicative of the highest nutrient concentrations, while the bottom two are indicative of slightly lower but still high levels of nutrient pollution.

8.8 SEDIMENTATION AS A KEY COMPONENT OF LAND-BASED POLLUTION

For similar reasons as increased epiphytic algal growth from nutrient pollution, increases in sedimentation can result in either decreased photosynthesis of the

zooxanthellae by cutting off sunlight and/or smothered coral polyps, making it difficult to feed. In both cases, smothering the reef with a blanket of algae or a blanket of sediment, the results are similar. The coral reef starves to death (DeGeorges, 1988a; 1989b; Wood, *et al.*, 1975; Johnson, *et al.*, 1988 all *In:* DeGeorges, 1990a; Evans, 2002).

“In Southeast Asia, Burke *et al.* (2002 *In:* Buddemeier, *et al.*, 2004) calculated that more than 21% of all coral reefs are threatened by sedimentation from land-based sources, primarily due to logging and poor agricultural practices. McCulloch Fallon, Wyndham, Hendy, Lough and Barnes (2003 *In:* Buddemeier, *et al.*, 2004) used coral skeletal records (1750–1998) to show that sediment delivery to the near-shore central Great Barrier Reef increased 5 to 10-fold with the introduction of European agricultural practices. These findings support the contention that significant portions of the Great Barrier Reef suffer chronic anthropogenic sediment stress (Wolanski, McCook & Sweatman, 2003 *In:* Buddemeier, *et al.*, 2004). Local dumping, dredging, land reclamation, mining, and construction activities can also result in increased sedimentation or resuspension of sediment in the marine environment” (Buddemeier, *et al.*, 2004).

8.8.1 Wetland Losses, Coastal Sedimentation and Solid Waste Pollution Associated with Urbanization in the Caribbean, Lessons for Africa

The problem of solid waste and the impacts resulting from inadequate disposal methods is a regional problem in the Caribbean and not a direct result of tourism (UNECLAC 1986), although addressing this issue becomes that much more critical if tourism is to become a major economic force in the region. East Africa will be faced with similar solid waste disposal problems as its coastal tourism develops. As affluence has reached the Caribbean islands, a growing middleclass and second homes for North American/Europeans have resulted in conversion of prime farmlands into suburbia. Little attention has been paid to solid waste (often dumped into guts-perennial stream beds) or to appropriate landscaping. In many

urban areas, garbage is collected and dumped into coastal wetlands (Johnson, *et al.*, 1988; Cambers, 1988; UNEP, 1988 all *In: DeGeorges, 1990a*):

- Directly into the sea at Choc Bay, Castries and into Soufriere Bay, Anse Chastinet in St. Lucia;
- Into a mangrove wetlands near St. Georges in Grenada;
- Into the Great Heed salt pond/mangrove system in St. Kitts;
- Into the sea at Port Elizabeth, Bequia;
- Into the Flashes mangrove system in Barbuda;
- Into a mangrove swamp on Ambergris Cay;

This physically destroys these wetlands. In many cases wetlands are filled-in (e.g., salt ponds and lagoons) and/or eliminated (e.g., mangroves) by developers.

Coral reef degradation is even greater in areas where the loss of wetlands has reduced nature's ability to filter nutrients and other pollutants before they reach the coral reef (Evans, 2002). Leachates from dumpsites also contaminate coastal waters with toxic pollutants (MAB, 1989 *In: DeGeorges, 1990a*). In most cases, these dumps are eyesores, within easy viewing of major tourist routes. The net result, when major rain events occur, is heavy sediment loads and other associated contaminants flushed into the sea on most Caribbean islands. One has to only visit a coastal area after a rain event to observe the brown ring and floating garbage encircling these islands. Not only is there a major public health risk from this runoff, but nearshore corals are also being smothered by such pollutants. This can also be occurring from malfunctioning septic tanks being exasperated during rain events. On a number of the islands, the U.S. embassy warns against swimming at such times.

Plastic pollution is a major problem in the Caribbean and after most rain events is commonly found in coastal tourism waters. Not only is this bad for tourism, but certain species of sea turtles (e.g., the loggerhead) are known to mistakenly ingest plastic for jellyfish and die. Plastics pollution became such a problem that in September 1988, the Texas land commissioner made a special trip to attend the Regional Seas Conference sponsored by UNEP in Mexico City. He pleaded with the Caribbean states to help control plastics pollution. Given the clockwise movement of currents in the Gulf of Mexico, these plastic wastes were washing up on the shores of Padre Island, Texas, destroying the aesthetic value of its beaches for tourism (DeGeorges, 1990a).

From October 27 – November 1, 2003, a UN Experts Meeting on Waste Management in Small Island Developing States was held in Havana, Cuba to look at solid waste disposal and sewage issues.

8.8.2 Coastal Sedimentation Affecting the Coral Reefs of Belize, Lessons for Africa

See above case study on land-based pollution, (see Section 8.5.1.3, Increase in land-based pollution from within Belize's frontier and Section 8.5.1.4, Possible increase in land-based pollution from outside Belize's frontier). This land-based pollution may be crossing international boundaries and affecting the second largest barrier reef in the world, figures varying from 201 km (125 mi.) (Smith, 1971) to 240 km (149 mi) (Littler, Littler, Bucher & Norris 1989) to 250 km (155 mi) long (Almada-Villela, McField, Kramer, Kramer & Arias-Gonzalez, 2002 *In: Wilkinson*, 2002). Pollution of mainland Tanzania could impact Zanzibar and visa versa, or pollution of Mahé, the Seychelles may be impacting islands just off its coast (see Section 8.12.1, Land-Based Pollution and Coral Reef Degradation Mahé, the Seychelles).

8.8.3 Sedimentation Associated with Sugar Cane, Lessons for Africa

On islands traditionally dominated by sugar cane such as Barbados and St. Kitts, the youth are turning away from manually cutting cane and large-scale mechanization is taking over. As in most parts of the world, this results in changed land use managed to handle large combines. Fields are enlarged and many traditional practices that would have minimized soil loss are abandoned (Oxenford, *pers. comm. In:* DeGeorges, 1990a). Personal observations by the principal author indicate that many of St. Kitts' coral reefs are smothered in sediment and/or sugar cane waste [see Table 8.6: Typical sewage treatment systems and impacts on coral reefs observed by principal author in the Caribbean (1989-1990)].

8.8.4 Sedimentation Associated with Banana Production, Lessons for Africa

In 1990, Britain had been subsidizing bananas for about 25 years on the Windward Islands of Grenada, St. Vincents, St. Lucia and Dominica: "Bananas are king". High quality bananas are produced by a few plantations located on suitable flatlands. The amount of land suitable for bananas is quite limited. As a result, the small-scale farmer is pushed onto land that is steep sloped and should not be farmed. Squatting on Crown lands is a problem on many of these islands and is resulting in a loss of tropical forests, which are important from the standpoint of biological diversity and as watersheds for the islands' drinking water supplies (Miller, Fugita & Ford, 1988 *In:* DeGeorges, 1990a).

Bananas do not adequately hold soils on these steep slopes. Additionally, herbicides, such as paraquat, are used to keep the under storage vegetation around banana trees to a minimum, leaving the ground bare and exposed for the most

part. When rain events occur, often severe and short in duration, huge quantities of sediment are washed into the coastal zone, creating a brown ring around these islands. This not only reduces light penetration in the water column, but eventually this sediment settles out, smothering the corals and sea grasses. The once beautiful El Cahuita Coral Reef off of Costa Rica is reputedly dead from heavy sedimentation associated with small-scale farmers producing bananas on steep slopes in the watershed that drains this reef (*Zadroga, pers. comm. In: DeGeorges, 1990a*).

8.9 IMPACTS OF PESTICIDES AND FERTILIZER FROM LAND-BASED POLLUTION ON CARIBBEAN CORAL REEFS, LESSONS FOR AFRICA

As Africa evolves into more intensive agriculture, pesticides washing into coastal areas could become a problem. Very little is known about the degree to which pesticides and fertilizers are a problem in the Caribbean. This, like sedimentation and nutrient pollution from sewage, is not monitored on most islands. Pesticides analysis requires sophisticated instrumentation and trained technicians to operate them. At the time of this evaluation in the late 1980s, a number of the islands had skilled technicians and inoperable gas chromatographs. This is due to a failure by decision-makers to perceive the need for such analyses. However, this was beginning to change, as the need to monitor residual pesticide levels on export crops became an economic necessity and because of an increasing awareness by the island communities that pesticide contamination, both direct (contamination of farm workers) and indirect (contamination of islanders from consumption of contaminated drinking water, vegetables, meat and seafood), was a major public health risk to the future of islands' residents. Pesticide control boards were becoming more active in controlling what pesticides were allowed into their countries. There was an increasing desire to assure that farm workers were

properly trained in safe pesticide handling and disposal. There were a number of instances reported from St. Vincent and Dominica where farm workers washed down contaminated pickup trucks or pesticide containers in local streams resulting in fish kills. On many of the “banana islands” (e.g., Grenada, St. Lucia, St. Vincent and Dominica), tremendous amounts of pesticides were used, primarily in banana production (DeGeorges, 1989c) (Table 8.8):

Table 8.8: Pesticide use in the Caribbean, 1988/89

Island	Annual Use of Pesticides (Active and Inert Ingredients)	Number of USEPA Restricted Pesticides
Grenada	102,040 kg (224,488 lb) (1988)	20
St Vincents	412,127 kg (906,679 lb) (1988)	10
St. Lucia	354,083 kg (759,182 lb) (Jan.-Oct. 1989)	13
Dominica	1,066,233 kg(2,345,712 lb) (1988)	11

Source: DeGeorges (1989c)

This comes out to 5.2-7.2 pounds of active ingredients per acre (2.7-3.7 kg/ha) in production per year compared to 23 pounds of active ingredients/acre in production/year (25.5 kg/ha) in San Joaquin County, California, known as one of the most intense areas for pesticide use in the world. The most commonly used USEPA restricted pesticides in the Caribbean at the time included the nematocides furadan (carbofuran), mocap (ethoprop) and vydate (oxamyl) and the herbicide gramoxone (paraquat) (DeGeorges, 1989c).

The Caribbean Environmental Health Institute conducted a study of pesticides and other toxic contaminants in St. Lucia's coastal waters. The findings were so shocking that the report has never been released. The Bellairs Research Institute found high levels of chlordane and other pesticides in coastal sediment, seagrass and in seaegg eggs (A local urchin, or “seaegg”, *Tripneustes ventricosus*, whose eggs are considered a local delicacy) (Hunte, 1989 *In:* DeGeorges, 1990a). Fish flesh was not analyzed. This pesticide had been banned from use in Barbados for

about ten years. It is a chlorinated hydrocarbon and very persistent in the environment. It is believed that this is only the tip of the iceberg. As there was an increasing awareness of the danger from agrochemicals and monitoring becomes more routine, it is likely that the severity of this problem will become better understood, both from a human and ecological prospective.

With regard to the impacts of fertilizer use on the coastal environment, this has not been quantitatively studied. On the Windward Islands, tremendous quantities of fertilizer are used in producing bananas. For instance on St. Lucia, it is estimated that 1,000 metric tons of N/P/K fertilizer are imported each month (DeGeorges, 1989c). Monitoring of streams and rivers draining agricultural lands into coastal waters will ultimately be required if the degree of nutrient and pesticide pollution in the coastal environment is to be ascertained. Coastal marine sediment, coral, seagrass and fish flesh also need to be monitored to determine if pesticides are bio-accumulating through the food chain.

8.10 OTHER CAUSES FOR CORAL REEF DEGRADATION

One of the major problems with much of the concern about what is happening to the coral reefs of the world is that there is insufficient quantitative data to scientifically and categorically state for each reef the exact cause of degradation. It is very important to establish long-term coastal monitoring programs so that this need can be met. Nevertheless, other causes of coral reef degradation include (DeGeorges, 1990a; Evans, 2002; Lazaroff, 2002):

- **Global ocean warming and coral bleaching;**
- **Coral diseases;**
- **Invasive species introduction;**
- **Coral and the aquarium trade;**

- **Sea urchin dieback** resulting in increased algal overgrowth due to the loss of this algal grazer;
- **Over-fishing of algal grazers**, such as parrotfish, contributing to increased algal growth covering the reefs;
- **Boat anchor, vessel groundage and diver damage;**
- **Sewage associated with sailboats and yachts; and**
- **Dredging and shoreline modification.**

Although global and regional issues must be addressed, for many other reasons than just coral reef dieback, there is a danger that they will obscure the more immediate and pressing issue of addressing land-based pollution. Furthermore, they do not lend themselves to immediate actions in which positive benefits may be observed. These issues also make it too easy for decision-makers to ignore doing anything about land-based pollution by using factors that are out of their control as the major reason for the coral reef's demise.

8.10.1 Global Ocean Warming and Coral Bleaching

Goreau (1997) and Goreau, Hayes, Clark, Basta and Robertson (1992, *In Geyer, 1992*) believed that coral reefs worldwide showed clear signs of severe stress due to high ocean temperatures over the last 15 years and would be unable to tolerate a further global warming of 1° C in surface air temperatures. Goreau (1998) considers elevated ocean temperatures of this warming phenomenon a greater threat than all other causes of coral reef degradation including sedimentation of soils eroded from deforested hill slopes, overgrowth by algae fertilized by sewage runoff, physical damage from dredging, boats, anchors and tourists, and from over-fishing.

It appears that beginning about 1988, global ocean warming may have become every bit as much of a threat to the health of coral reefs as land-based pollution, resulting in massive coral bleaching (Figure 8.5). Dr. Tom Goreau (2002), president of the Global Coral Reef Alliance, had this to say about global warming and coral reefs at a presentation made at the World Summit on Sustainable Development (WSSD).

“Ten years ago in Rio de Janeiro we were the only ones who warned the governments of the world that failure to immediately halt global warming would result in most corals dying of heat stroke in the coming decade. Instead of acting decisively to save our most precious and beautiful marine resources, they adopted a worthless Framework Convention on Climate Change to stabilize not global temperatures, but the rate of temperature increase, thereby condemning the world’s reefs to death even if they had lived up to their commitments, and violating the goal of the Convention to protect the most climatically-sensitive ecosystems.

Since then most of the world’s coral has died “from heatstroke across the entire Indian Ocean and the Northwest Pacific in 1998, from heatstroke across the entire South Pacific in 2002, from heat shock, soil erosion, strangulation by algae over-fertilized by sewage and fertilizers, and from diseases in the Caribbean, and from the devastating use of bombs and poisons for fishing in Indonesia, the Philippines, and Southeast Asia, the richest reefs of all, the underwater Amazon Jungle and Congo Rainforest rolled into one. The first global human climate change caused ecosystem extinction is now well underway. It will not be the last. It is now too late to derail or delay the disaster. While the overall dimensions of the catastrophe are already clearly evident, the details of when and where remain unpredictable... With increasing temperatures, corals are dying, and the reefs are no longer able to grow to match rising sea level, just as sea level rise, now several millimeters per year, is starting to accelerate. As mountain glaciers melt and as polar ice caps are lubricated from below by melt water, there could be sudden unpredictable surges as ice suddenly slides into the ocean. Tropical countries, surrounded by dead and dying reefs, have lost their ability to resist increased storm waves and flooding that will follow. Old ecosystems and fisheries will be disrupted and die before new ones can replace them. Only a few

places on the coldest edges of reefs, like South Africa, will benefit as corals slowly spread away from warmer areas, but it will take thousands of years for these reefs to mature, if they are left undisturbed..." (Goreau, 2002).

8.10.1.1 Coral bleaching and its causes

Coral bleaching is the whitening of corals that occurs when the zooxanthellae are lost from coral tissues or the amount of photosynthetic pigment in the zooxanthellae is sharply decreased. Because corals can only survive in a limited range of conditions, a slight temperature increase over a prolonged period can result in bleaching. Stresses from pollution (e.g., nutrients, sedimentation), high levels of light, infections, excess shade and fluctuations in salinity levels are also associated with incidents of coral bleaching (Williams & Williams, 1990 *In:* Goreau, Cervino, Goreau, Hayes, Hayes, Richardson, Smith, DeMeyer, Nagelkerken, Garzon-Ferrera, Gi, Garnison, Williams, Bunkley-Williams, Quirolo, Patterson, Porter & Porter, 1998; Glynn, 1991; Kushmaro, Loya, Fine & Rosenberg, 1996 *In:* Goreau, *et al.*, 1998; U.S. Dept. of State, 1998c; Pomerance, 1999; Turner, 2002; Fitt, McFarland, Warner & Chilcoat, 2000; Fitt, Brown, Warner & Dunne, 2001 *In:* Buddemeier, *et al.*, 2004). While most bleached colonies die, those that survive stop growing and reproducing (Pomerance, 1999; U.S. Dept. of State, 1998c; 2001; Turner, 2002; Mendes & Woodley 2002 *In:* Buddemeier, *et al.*, 2004). Goreau and Hayes (2005b) note reduction in organic and gaseous nutrient for the coral, low rates of sexual reproduction, cessation of tissue growth and halting growth of limestone skeleton as a result of thermal damage to the zooxanthellae followed by its expulsion.

Goreau and Hayes (1994) were among the first scientists to report the impacts of increasing ocean temperatures on mass coral bleaching. If the sea surface temperature (SST) increased 1° C for a month or longer above the long-term

average for the warmest months/season, the period was termed “a hot spot” and usually resulted in mass bleaching of coral reefs. Threshold temperatures were found “higher at sites with higher mean temperature, indicating that coral populations are adapted to local conditions. Mass bleaching was reported in some of the coldest and hottest coral reef areas, showing that both are vulnerable” (Goreau & Hayes 1994). They ruled out pollution as mass bleaching was occurring on pristine reefs as much or more than on coral reefs exposed to land-based pollution (Goreau & Hayes, 1994). Goreau and Hayes (2005a) have been able to demonstrate that satellite images of SST are accurate enough to correlate with mass coral bleaching. If these conditions last only one month and it then cools down, almost all corals will gradually recover. If excessively hot surface water conditions persist for two to three months or if surface water temperatures reach 2° or 3° C above average for one month, coral mortality becomes significant (Goreau, 1998). In the Caribbean, once seawater temperatures reach about 30° C for a few weeks, corals can begin experiencing “bleaching”, the degree of bleaching appearing to increase with the length of period of elevated surface water temperatures (Goreau, *et al.*, 1992 *In:* Geyer, 1992). Monthly average sea surface temperatures in the Seychelles normally do not get much over 29° C, but in 1998, they stayed over 30° or 31° C for at least five months (Goreau, 1998).

El Niño-Southern Oscillation events have increased in frequency and intensity over the last few decades. This combination of global warming and intense El Niño events has resulted in a dramatic increase in coral bleaching (Goreau, *et al.*, 1992 and Glynn, 1993; Brown, 1997; Wilkinson, 2000 all *In:* Buddemeier, *et al.*, 2004). “Analyses of global satellite-derived SST anomalies and coral reef bleaching reports since 1982 show that both are rapidly increasing”. Supra-threshold events, where a combination of global warming appears to be driving El Niño events above regional temperature thresholds in those areas with strong

positive El Niño Southern Oscillation Index (ENSO) correlations. Impacting over 100 countries, if warming continues, bleaching events may become an annual recurrence,

“placing many reef tracts at high risk of catastrophic mass mortality from bleaching. These changes are concurrent with declining live coral cover, ecosystem function, and economic values of coral reefs from both emerging diseases and other anthropogenic and natural stresses, but have greatly exceeded their cumulative impact in 1998” (Goreau & Hayes, 2005b).

8.10.1.2 Global ocean warming, Caribbean and Pacific

In 1982-83, 70-95% of the corals in Costa Rica, Panama, Colombia, and the Galápagos Islands died because of bleaching caused by the warm waters brought by El Niño (ENSO) (movement of currents affecting on- and offshore-temperatures). The death of some species of corals removed protection against predators such as the crown of thorns starfish. Increased erosion of the coral skeletons by sea urchins resulted in destruction of these reefs that continues today. Erosion of reef frameworks in Panama has exceeded 1 inch per year. Many of these reefs have still not recovered and the bleaching subsequently moved on to many areas of the Caribbean and western Atlantic Ocean. In the late 1980s and early 1990s, bleaching became a regular and pervasive problem in the Caribbean and began to appear in the Pacific and Indian Oceans -- often related to El Niño events. During the El Niño of 1997-98, bleaching began in the eastern Pacific but then expanded to an unprecedented, alarmingly broad region across the Indian Ocean from Kenya to Indonesia and in the Pacific Ocean from Australia to Polynesia. Bleaching reports continue in the fall of 1998, now across the western Atlantic basin. This increase in bleaching corresponds to increased ocean temperatures that have been seen across the tropical Pacific and Atlantic since 1976 (U.S. Dept. of State, 1998c; Pomerance, 1999).

8.10.1.3 Global ocean warming and coral bleaching, Western Indian Ocean

Coral bleaching occurred in the western Indian Ocean as a result of increased sea surface temperatures over a period of a couple of months in 1998 (Warrick, 1999). Goreau (2005) states,

“I warned all of these groups you cite across the Indian Ocean that bleaching was about to happen before they could see it in the field, and made sure that people were alerted in time to see the first changes. Due to the political need to control money and credit, Wilkinson and Linden moved in to take over, and deliberately cut out all reference to the fact that all of these teams had been previously warned by us. My 3 reported studies in the Seychelles were the only ones in the world to look at the same transects before, during, and after bleaching”.

Wilkinson (2004) explains that this was a one in 1,000 year event in many places with no recorded history of such events, though there is concern that such events will become much more commonplace in the next 50 years linked to global climate change. Many 1,000-year old corals died. Preliminary data indicate that more than 70% of corals died off across a wide region of the Indian Ocean, from the coast of Kenya to the Lakshadweep Islands off southern India (Warrick, 1999). In the Maldives, post-bleaching data in 1998 shows the mean cover of live coral was 2.1%, ranging from 1.0% - 3.1% among surveyed atolls compared to pre-bleaching levels of between 46.5% and 37.4% (Zahir, 2002 *In:* Linden, *et al.*, 2002). Off Sri Lanka, mortality reached 50-100% among shallow corals, while corals deeper than 10 m appear to have recovered (Rajasuriya, Maniku, Subramanian & Rubens 1999; Wafar, 1999; Rajasuriya & Karunaratna, 2000; Zahir, 2000 all *In:* Wilhelmsson, 2002 *In:* Linden, *et al.*, 2002). Nearly all corals of the dominating genus *Acropora* and also *Echinopora lamellosa* died and the reef was covered with filamentous algae (Rajasuriya & Karunaratna, 2000 *In:*

Wilhelmsson, 2002 *In:* Linden, *et al.*, 2002). Off East and Southern Africa, this included the following:

- Surveys in Kiunga and Malindi (Kenya), Misali and Mafia (Tanzania) and Pemba and Inhaca (Mozambique) showed that 90–100% of the corals died after exposure to water temperatures that exceeded 32°C, mainly in March and April 1998. In most affected areas, the cover of algal turf on dead or bleached coral increased significantly, as much as a 200% increase was noted on Kenyan reefs (CORDIO, 1999);
- Wilkinson (2002) estimates a loss of up to 80% live coral on Kenyan and Tanzanian reefs with very slow recovery, particularly on reefs with direct human pressures. Obura, Celliers, Machani, Mangubhai, Mohammed, Motta, Muhandu, Muthiga, Pereira and Schleyer (2002 *In:* Wilkinson, 2002) estimate 50-90% coral mortality off Kenya/Tanzania;
- In Kenya, there was an 80% or greater bleaching and mortality rate, below 10m there was a less than 50% mortality in northern Kenya (Linden, *et al.*, 2002);
- The coral mortality rate was more than 80% in the Mafia Marine Park off Tanzania (Warrick, 1999; Linden, *et al.*, 2002); and
- Bleaching and mortality levels were less than 1% in South Africa (Schleyer & Celliers, 2002 *In:* Linden, *et al.*, 2002; Obura, *et al.*, 2002 *In:* Wilkinson, 2002). However, a protracted period of elevated temperatures with high levels of irradiance caused by exceptional water clarity elicited measurable bleaching in 2000, at a critical temperature of ~28.8°C continuously over about four to five days, about 2 degrees less on these sub-tropical reefs than the tropical reefs further north (Schleyer & Celliers, 2002 *In:* Linden, *et al.*, 2002; Wilkinson, 2002).

There has also been apparently some recovery off East Africa, though other areas appear to continue declining in coral cover (Table 8.9).

Table 8.9: Percent coral cover during 1997/98 (pre-bleaching), 1999 and 2001/02 at monitoring sites in East Africa			
	1997/98	1999	2001/02
KENYA			
-Northern Kenya (>10 m deep)	-	5.7	1.2
-Northern Kenya (< 3 m deep)	13.2	5.1	9.9
-Southern Kenya (Protected)	39.6	11.4	19.5
-Southern Kenya (Unprotected)	20.6	11.4	14.4
-Overall	26.3	8.1	11.25
TANZANIA			
-Tanga	53.0	33.3	-
-Pemba	53.7	12.3	16.3
-Unguja	45.8	32.0	37.9
-Kunduchi	43.0	35.0	-
-Mafia	73.3	19.4	24
-Songosongo	35.0	37.5	-

Obura, *et al.* (2002 *In:* Wilkinson, 2002) state that degraded reefs outside marine protected areas (MPAs) of East Africa severely damaged by the 1997/8 El Niño event have recovered 50-100% of pre-bleaching coral cover. This does not say that they have recovered 50-100%, but that they are 50-100% of what they were before the bleaching which could be good if anthropogenic influences have been reduced but could mean further degradation if land-based pollution (e.g., from

coastal development) and other human impacts (e.g., dynamite fishing) have not been removed. Recruitment of corals to the reefs has been moderate, with highest levels on protected reefs with high coral cover and diversity. In 2001-2002, additional damage to East Africa reefs included floods in Mozambique, algal blooms off Tanzania and Kenya and an unknown fungal disease of corals off Kenya and northern Tanzania (see Section 8.11.1, Coral Degradation off East Africa). It is noted (Wilkinson, 2002) that:

- Recovery is only slow to moderate along the East African coastline and in the Comoros, Seychelles and Maldives particularly where reefs are stressed by sediments and nutrients and there are insufficient protected areas to ensure coral reef sustainability; and
- Madagascar, Mauritius and Reunion escaped most of the 1998 bleaching; however, reefs under more human pressure are declining, especially on Madagascar.

Obura *et al.* (2004 *In: Wilkinson, 2004*) and Wilkinson (2004) found that for East Africa 30% of the reefs declined from bleaching with a slow recovery due to human population pressures further exacerbated by increases in fishing pressure. Recovery of corals since 1998 is estimated at about 30-50%; however, recovery has been very patchy with many depleted reefs showing no recovery.

“However, many of the reefs that have shown ‘full recovery’ to pre-bleaching levels had displayed signs of human induced degradation prior to the bleaching. The apparent rate of recovery was more rapid on these degraded reefs, but only on coral communities that already had lost many slow growing and vulnerable coral species and was instead dominated by opportunistic (*Pocillopora*, *Stylophora*, branching *Porites*) and stress resistance species (massive *Porites*, *Coscinaraea*, *Pavona*). In contrast, the reefs showing the least recovery since 1998 are those that were in better health prior to bleaching. Recovery on these reefs has been affected by chronic and local threats,

including over-fishing, crown-of-thorns starfish (COTS - *Acanthaster planci*) infestations and repeated minor bleaching events" (Obura *et al.*, 2004 *In: Wilkinson, 2004*).

Wilkinson (2004) notes off East Africa that "the growing coastal population of 22 million (people) poses the largest threat to the reefs, with land-based activities and over-fishing increasing. There have been significant improvements in the management of coral reef MPAs in the last 2-4 years..." (Tables 8.3, 8.9 & 8.10).

CATEGORY	Kenya	Tanzania	Mozambique	South Africa	Region
1. Seriously damaged or totally destroyed	10	10	10	0	7.5
2. Strong recovery since 1998	30	30	30	NA	30
3. High Risk: clear damage	30	20	20	10	20
4. Medium Risk: moderate damage	30	30	10	30	25
5. Low Risk: healthy & relatively stable	0	10	30	50	22.5
Significance of categories					
1 = 90% of the coral are gone & unlikely to recover soon					
3 = 50-90% loss of corals & likely to join "Category 1" in 10 to 20 years					
4 = Moderate signs of damage – 20-50% loss of corals & likely to join "Category 1" in 20 to 40 years					
NA = Not applicable, as there were no losses in 1998					
Source: Obura, <i>et al.</i> (2004 <i>In: Wilkinson, 2004</i>) with permission, AIMS.					

In this case recovery implies that a quantity of coral off East Africa was bleached, losing its zooxanthellae, but did not die, eventually recovering as temperatures declined and/or different monitoring techniques and/or monitors were introduced, resulting in different interpretations. In fact, Goreau (2005) states that much of the recovery in the western Indian Ocean is about surviving coral recovering, mostly *Porites spp.*, with actual recruitment being very low in most places.

With a projected coastal population growing from 10-15 million in 1994, 22 million in 2004 to 39 million by 2014, with the potential for more bleaching

events, the future prognosis for coral reefs off the East African Coast is poor (Obura *et al.*, 2004 *In:* Wilkinson, 2004) unless land-based pollution and fishery management issues are properly addressed.

Based on willingness of tourists to pay/day to see healthy reef, losses from this global warming event were estimated to be US\$ 71.5 million for the Seychelles, US\$ 47.2 million for Mombassa and US\$ 39.9 million for Zanzibar alone in net present values over a 20-year period with a 10% discount rate (Linden, *et al.*, 2002).

Coral reefs in the five states of the southwestern Indian Ocean Island Node collectively cover an area of 5,270 km² and are very important for coastal protection, especially from the frequent strong cyclones south of 10° South (Ahamada, Bijoux, Bigot, Cauvin, Koonjul, Maharavo, Meunier, Moine-Picard, Quod & Pierre-Louis, 2004 *In:* Wilkinson, 2004):

- Coral mortality ranged from 50–90% over extensive areas of shallow reefs in the Seychelles, Comoros, Madagascar and Chagos. In some areas (around Mahé, the Seychelles), mortality was close to 100%, with algal turf covering much of the reefs by the end of 1998 (CORDIO, 1999);
- Comoros experienced over 55% of the corals dying, Madagascar 30% and Mauritius 1 to 15%. (Linden & Sporrong 1999 *In:* Payet, Soogun, Ranaivoson, Payet & Abdallah, 2003);
- The Seychelles was perhaps the most severely affected, with live coral cover on the granitic islands reduced to less than 10% (90% die-off or more) in some areas (Linden & Sporrong 1999 *In:* Payet, *et al.*, 2003). Goreau (1998) estimates that at 14 sites in the Seychelles 50-90% of the coral was recently killed by high surface water temperatures, while Warrick (1999) records 75% mortality in the Seychelles; and

- Localized bleaching was recorded in 2001 around Reunion and in March 2002 around Rodrigues and the Seychelles (Ahamada, *et al.*, 2002 *In: Wilkinson*, 2002).

Similar observations were made by Goreau, Hayes and McClanahan (2000).

Very high settlement of new corals in Indonesia, low rates in the Maldives and very low rates in the Seychelles were being observed in 2003/2004 (Goreau, 2004f), so there is some recovery. Linden, *et al.* (2002) discuss some recovery since the 1998 die-off across the Indian Ocean.

Wilkinson (2004) notes in the southwestern Indian Ocean (e.g., the Seychelles, Comoros, Reunion, Mauritius, Madagascar) that

“there has been some recovery of coral reefs, which had been reduced to less than 5% coral cover in 1998. However, recent bleaching damage to the new coral recruits is slowing recovery. Alongside these, there are some exceptional sites that were highly resilient to the bleaching damage; but human stresses and natural disturbances pose a constant threat to these reefs”.

By 2014,

“if management does not improve and there are repeats of the recent climate-related stresses, it is predicted that most reefs in the region will have less than 20% live coral cover by 2014. Many species of corals and fish will be locally extinct due to losses from coral bleaching and over-exploitation of some fish and invertebrate species” (Ahamada, *et al.*, 2004 *In: Wilkinson*, 2004).

A detailed island-by-island analysis of the status of coral reefs and reef fishes is provided by Ahamada, *et al.* (2004 *In: Wilkinson*, 2004).

8.10.1.4 Possible expansion of coral distribution from global warming

As discussed in Section 8.2.7.1 Temperature, colonial reef-building coral reefs are found at temperatures above 16-18° C (61-64° F). Global warming may extend the range of corals into areas that are currently too cold (Precht & Aronson, 2003 *In: Buddemeier, et al., 2004*), a 2°C (4°F) warming of the oceans expanding the range by a few degrees latitude. Locations within this region that have suitable depth, substrate and other environmental conditions could potentially support new coral reefs at the higher temperatures. However, even with warmer waters, there are other physical limitations that will limit the expansion of coral reefs (*Buddemeier, et al., 2004*):

- The west coasts of North and South America, Europe and Africa experience upwellings and cool water flowing toward the equator; and
- Along the coasts of the southeastern United States (also the Gulf of Mexico) and near the Amazon River, reef expansion will be blocked by muddy coastal shelves, river deltas and turbid water.

Wilkinson (2004) hypothesizes that

“the possibility of coral reefs migrating to higher latitudes towards the poles is unlikely, as there are few suitable broad continental shelves in these latitudes and corals rely on photosynthetic energy from their symbiotic zooxanthellae. They will not receive sufficient sunlight energy during the higher latitude winters”.

Similarly Goreau, Hayes and McAllister (2005) conclude that in areas with increased upwelling due to global climate change, corals may survive in cooler waters or waters where warming is slowest,

"however they will persist in marginal coral communities, not constructional coral reefs, due to increased competition from algae and filter feeders", likely due to the fact that upwelling areas tend to be rich in nutrients giving epiphytic algae and ahermatypic corals a comparative advantage over reef-building (hermatypic) corals - "temperate waters are too eutrophic to permit healthy reef growth even if temperatures were adequate".

Otherwise hermatypic coral reefs found in equatorial regions, occupying the warmest habitats that will likely become warmer,

"are going extinct because there is no place for organisms already adapted to warmer habitats to migrate from" (Goreau, *et al.*, 2005).

Thus,

"only southern China, Japan, Australia, and southern Africa offer realistic opportunities for reef expansion. Additionally, sea surface temperature (SST) gradients are very steep in the vicinity of 18°C (the annual minimum temperature threshold for coral reef growth), and ocean model projections suggest that SST warming associated with doubled CO₂ will only move the 18° C contour by a few hundred kilometers, especially in the critical western boundary areas (Kleypas, Buddemeier & Gattuso, 2001 In: Buddemeier, *et al.*, 2004). The overall positive effects of warming on habitat availability and ecosystem distribution will be very minor compared to the overall negative effects" (Buddemeier, *et al.*, 2004).

Even if corals could expand into these areas, one must ask how many 100s or 1,000s of years it would take for them to develop the structures that current reefs have built up over 10,000 of years of the interglacial period (Buddemeier, *et al.*, 2004).

"The other major mechanism is for corals to adapt or acclimate to rising temperatures, and there is encouraging early evidence, that corals may be able to swap their symbiotic algae for more temperature resistant ones and continue to

grow in higher water temperatures" (Wilkinson, 2004). However, Goreau (2005) believes that claims of coral adaptation or zooxanthellae switching is not supported by available data. He explains that corals cannot adapt physiologically, do not change their zooxanthellae and if they could this would need evolutionary time, which we are not giving them.

8.10.1.5 Future global warming

There is concern that burning of fossil fuels will continue to result in rising air temperatures globally and thus increasing ocean temperatures (Table 8.11).

VARIABLE	OBSERVED RANGES		PROJECTED RANGES	
	1880 (Pre-Industrial)	2000	2050	2100
CO₂ (parts per million by volume - ppmv)	280	367	463-623	478-1,099
Global Mean Temperature				
Centigrade (°C)	---	+0.4 – 0.8	+0.8 – 2.6	+1.4 – 5.8
Fahrenheit (°F)	---	+0.7 – 1.4	+1.4 – 4.7	+2.5 – 10.4
Sea Level				
Meters (M)	---	+ 0.07 – 0.15	+ 0.05 – 0.32	+ 0.09 – 0.88
Feet (Ft.)	---	+0.23 – 0.49	+0.16 – 1.0	+0.29 – 2.88
Note: Year 2050 and 2100 temp. and sea level increases against Year 2000 baseline				
Note: The Centigrade versus Fahrenheit data shown is not a direct conversion based on the formula: F = (9/5 x C) + 32, (e.g., one cannot take 0.8 and convert it to 1.4), but the relative increase in temperature within a given temperature range within one system at a ratio of about 1.8. For instance if the temperature increased from 10 to 12 °C, the difference is 2°. In Fahrenheit, they increased from 50 to 53.6, a difference of 3.6 °F at a ratio of 3.6/2 = 1.8 that appears to be a relative constant.

8.10.1.6 Global warming, human-made versus a natural cycle

The impacts of global warming are something that must be dealt with at international levels such as through the Kyoto Protocol to the United Nations

Framework Convention on Climate Change. Land-based pollution is something that individuals and communities can actually put their fingers on and do something about. There are still major debates as to the causes of global warming. One of the biggest opponents of what many scientists see as a politicization of the global warming issue is Dr. Richard S. Lindzen, Sloan Professor of Meteorology at the renowned Massachusetts Institute of Technology (MIT) Department of Earth, Atmospheric and Planetary Sciences. Lindzen (2001a) in a presentation to the U.S. Senate Environment and Public Works Committee stated that where there is widespread agreement among scientists is:

- “That CO₂ levels have increased from about 280 ppm (parts per million) to 360 ppm over the past century...
- That the increase in global mean (air) temperature over the past century is about 1°F (0.34°C)...
- That doubling CO₂ alone will only lead to about a 2°F (0.68°C) increase in global mean (air) temperature...
- That the most important energy source for extra-tropical storms is the temperature difference between the tropics and the poles which is predicted by computer models to decrease with global warming...Consistent with this, even the IPCC (the United Nation’s Intergovernmental Panel on Climate Change) Policymakers Summary notes that no significant trends have been identified in tropical or extra-tropical storm intensity and frequency. Nor have trends been found in tornados, hail events or thunder days (from global warming)...
- That temperature increases observed thus far are less than what models have suggested should have occurred even if they were totally due to increasing greenhouse emissions...
- That claims that man has contributed any of the observed warming (i.e. attribution) are based on the assumption that models correctly predict natural variability. Such claims, therefore, do not constitute independent verifications of models. Note that natural variability does not require any external forcing²⁰⁹ – natural or anthropogenic;

²⁰⁹ Climate forcing is defined as an imposed perturbation of the earth's energy balance. Climate forcing is typically measured in watts per square meter (W/m²). The sensitivity of the climate system to a prescribed forcing is commonly expressed in terms of the global mean temperature

- That large computer climate models are unable to even simulate major features of past climate such as the 100 thousand year cycles of ice ages that have dominated climate for the past 700 thousand years, and the very warm climates of the Miocene, Eocene, and Cretaceous. Neither do they do well at accounting for shorter period and less dramatic phenomena like El Niños, quasi-biennial oscillations, or intra-seasonal oscillations – all of which are well documented in the data;
- That major past climate changes were either uncorrelated with changes in CO₂ or were characterized by temperature changes which preceded changes in CO₂ by 100s to thousands of years;
- That increases in temperature on the order of 1°F (0.34°C) are not catastrophic and may be beneficial; and
- That Kyoto, fully implemented, will have little detectable impact on climate regardless of what one expects for warming. This is partly due to the fact that Kyoto will apply only to developed nations. However, if one expected large global warming, even the extension of Kyoto to developing nations would still leave one with large warming”.

A National Academy of Sciences (NAS) (NAS, 2001) review of global warming including the IPCC report concluded that greenhouse gases are accumulating in the earth's atmosphere because of human activities, causing surface air temperatures and subsurface ocean temperatures to rise. Of the greenhouse gases that are directly influenced by human activity, the most important are carbon dioxide (CO₂), methane (CH₄) – 19%, water vapor (H₂O), ozone (O₃), nitrous oxide (N₂O), and chlorofluorocarbons (CFCs including CFC-12 (CCl₂F₂) and CFC-11 (CCl₃F). Changes observed over the last several decades are mostly due to human activities, but cannot rule out that some significant part of these changes is also a reflection of natural variability.

change that would be expected after a time sufficiently long for both the atmosphere and ocean to come to equilibrium with the change in climate forcing.

Human-induced warming and associated sea level rises are expected to continue through the 21st century. Significant increases have been recorded of (NAS, 2001):

- CO₂ (increase from 280 ppmv pre-industrial to ~370 ppmv today);
- CH₄ (1% per year increase from 1978, until about 1990. The rate of increase slowed and became more erratic during the 1990s); and
- N₂O (increasing approximately 13% increase in the past 200 years).

Global warming rates as large as 2°C (3.6°F)²¹⁰ per millennium may have occurred during the retreat of the glaciers following the most recent ice age. Global mean surface air temperature warmed by about 0.4-0.8°C (0.7-1.5°F) during the 20th century. The ocean, which represents the largest reservoir of heat in the climate system, has warmed by about 0.05°C (0.09°F) averaged over the layer extending from the surface down to 10,000 feet, since the 1950s. Climate change simulations based on IPCC emissions scenarios yield a globally-averaged surface air temperature increase by 2100 of 1.4 to 5.8°C (2.5 to 10.4°F) relative to 1990 (NAS, 2001).

There is general agreement that observed warming is real and particularly strong within the past 20 years. Whether it is consistent with the change that would be expected in response to human activities is dependent on what assumptions one makes about the time history of atmospheric concentrations of the various forcing agents, particularly aerosols. Predicted warming is larger over higher latitudes than over low latitudes, especially during winter and spring, and larger over land

²¹⁰ Note: The Centigrade versus Fahrenheit data shown in NAS (2001) is not a direct conversion based upon the formula: $F = (9/5 \times C) + 32$, (e.g., one cannot take 0.8 and convert it to 1.4), but the relative increase in temperature within a given temperature range within one system at a ratio of about 1.8. For instance, if the temperature increased from 10 to 12 °C, the difference is 2°. In Fahrenheit, they increased from 50 to 53.6 a difference of 3.6 °F, at a ratio of $3.6/2 = 1.8$ that appears to be a relative constant.

than over sea. Rainfall rates and the frequency of heavy precipitation events are predicted to increase, particularly over the higher latitudes. Higher evaporation rates would accelerate the drying of soils following rain events, resulting in lower relative humidities and higher daytime temperatures, especially during the warm season. Because there is considerable uncertainty in current understanding of how the climate system varies naturally and reacts to emissions of greenhouse gases and aerosols, current estimates of the magnitude of future warming should be regarded as tentative and subject to future adjustments (either upward or downward). Because of the large and still uncertain level of natural variability inherent in the climate record and the uncertainties in the time histories of the various forcing agents (and particularly aerosols), a causal linkage between the buildup of greenhouse gases in the atmosphere and the observed climate changes during the 20th century cannot be unequivocally established (NAS, 2001).

In a Wall Street journal article (Lindzen, 2001b), Dr. Lindzen goes on to summarize conclusions of the U.S. National Academy of Sciences (NAS) report (NAS, 2001), of which he was one of eleven contributing scientists,

“We are quite confident: (1) That global mean temperature is about 0.5°C (0.9°F) higher than it was a century ago; (2) That atmospheric levels of carbon dioxide have risen over the past two centuries; and (3) That carbon dioxide is a greenhouse gas whose increase is likely to warm the earth (one of many, the most important being water vapor and clouds). But -- and I cannot stress this enough -- we are not in a position to confidently attribute past climate change to carbon dioxide or to forecast what the climate will be in the future. That is to say, contrary to media impressions, agreement with the three basic statements tells us almost nothing relevant to policy discussions...Distinguishing the small recent changes in global mean temperature from the natural variability, which is unknown, is not a trivial task. All attempts so far make the assumption that existing computer climate models simulate natural variability, but I doubt that anyone really believes this assumption. We simply do not know what relation, if any, exists between global climate changes

and water vapor, clouds, storms, hurricanes, and other factors, including regional climate changes, which are generally much larger than global changes and not correlated with them. Nor do we know how to predict changes in greenhouse gases...My own view, consistent with the panel's work, is that the Kyoto Protocol would not result in a substantial reduction in global warming".

More recently, some have claimed major flaws in temperature change models (Muller, 2004). The American Meteorological Society (AMS, 1990) concluded that

"at present, observations suggest, but are insufficient to prove, that atmospheric warming caused by human activities has already occurred. Climate models, which are simplified mathematical representations of the complex climate system, are the principal means available to predict or project the magnitude, timing, and spatial distribution of global climate change. General Circulation Models (GCMs), the most comprehensive physically-based models of the climate system, currently provide the best estimates of future global warming. These suggest that global warming will occur, though the magnitude and timing of this warming are debatable. However, even the most comprehensive present day models now in existence have significant limitations. These limitations, which are expected to diminish as model improvements occur, could be masking elements which would produce greater warming or could be causing over-estimates of the warming to be anticipated".

The American Geophysical Union (AGU, 2003) official position on global warming, "Human Impacts On Climate Change" includes but is not limited to the following.

"...Scientific evidence strongly indicates that natural influences cannot explain the rapid increase in global near-surface temperatures observed during the second half of the 20th century. Human impacts on the climate system include increasing concentrations of atmospheric greenhouse gases, air pollution, increasing concentrations of airborne particles, and land alteration. A particular concern is that atmospheric levels of carbon dioxide

may be rising faster than at any time in Earth's history, except possibly following rare events like impacts from large extraterrestrial objects...Mid-continent warming will be greater than over the oceans, and there will be greater warming at higher latitudes. Some polar and glacial ice will melt, and the oceans will warm; both effects will contribute to higher sea levels. The hydrologic cycle will change and intensify, leading to changes in water supply as well as flood and drought patterns...The complexity of the climate system makes it difficult to predict some aspects of human-induced climate change: exactly how fast it will occur, exactly how much it will change, and exactly where those changes will take place...model projections of future global warming vary, because of differing estimates of population growth, economic activity, greenhouse gas emission rates, changes in atmospheric particulate concentrations and their effects, and also because of uncertainties in climate models... AGU believes that no single threshold level of greenhouse gas concentrations in the atmosphere exists at which the beginning of dangerous anthropogenic interference with the climate system can be defined...AGU encourages scientists worldwide to participate in climate research, education, scientific assessments, and policy discussions. AGU also urges that the scientific basis for policy discussions and decision-making be based upon objective assessment of peer-reviewed research results...Scientific research is required to improve our ability to predict climate change and its impacts on countries and regions around the globe. Scientific research provides a basis for mitigating the harmful effects of global climate change through decreased human influences (e.g., slowing greenhouse gas emissions, improving land management practices), technological advancement (e.g., removing carbon from the atmosphere), and finding ways for communities to adapt and become resilient to extreme events”.

A 2004 conference on global warming hosted by the American Association for the Advancement of Science (AAAS, 2004) raised major concerns over humans' acceleration of global warming.

The climate change debate has become corrupted by politics, the media and support for research depending on alarm (Dr. R.S. Lindzen In: Morano, 2004). The IPCC (2007) comes out strongly in favor of humans having a major impact

on climate change from increases in green house gas emissions; carbon dioxide primarily to fossil fuel use and land-use change, with methane and nitrous oxide primarily due to agriculture. However, a U.S. Senate (2007) report featuring 400 prominent peer-reviewed scientists from diverse fields, a number among the 52 scientists participating in the 2007 IPCC Summary for Policymakers, urges caution over what degree human's are the major cause of global warming. The debate will continue, but regardless of the cause or degree of the cause; natural, human-induced or a combination thereof, global ocean warming has been devastating to coral reefs and in the long-term may impact on their distribution.

8.10.1.7 Increased CO₂ (carbon dioxide) levels impacting coral growth

A second concern associated with the burning of fossil fuels, in addition to global warming, is increased carbon dioxide (CO₂) levels. Increasing atmospheric CO₂ drives more CO₂ into the ocean, lowering the pH²¹¹ (making the ocean more acidic) and changing the relative proportions of the three forms of carbon: CO₂ (dissolved CO₂ and carbonic acid - H₂CO₃), bi-carbonate (HCO₃⁻) and carbonate (CO₃²⁻).

Under pre-industrial conditions in the tropics, about 85% of dissolved CO₂ was in the form of bicarbonate and 15% in the form of carbonate. Doubling the CO₂ levels in sea water in these tropical areas, assuming salinity at 35 ppt. and 25°C over pre-industrial levels, could result in 90% taking the form of bicarbonate and 10% of carbonate, which would reduce the calcification process in corals which

²¹¹ pH is a measure of free hydrogen ion activity not bound by carbonate or other bases in water, pH = -log₁₀ [H⁺], where [H⁺] is hydrogen ion activity. A pH of 7 is neutral, while below a pH of 7 indicates increasing acidic conditions and above indicates increasing basic conditions

combine calcium and carbonate to form calcium carbonate: $\text{Ca}^{+2} + \text{CO}_3^{-2} \leftrightarrow \text{CaCO}_3$ that forms the coral skeleton. During these pre-industrial conditions, pH levels, a reflection of acidity and of shallow ocean waters, were slightly basic at 8.15 decreasing today to about 8.05 (Buddemeier, *et al.*, 2004).

Higher atmospheric CO₂ increases ocean acidity (e.g., lowers the pH) and lowers the concentration of carbonate which corals and other marine organisms use, in the form of calcium carbonate, to build their skeletons. Thus,

“continued growth in human emissions of CO₂ will further limit the ability of corals to grow and recover from bleaching events or other forms of stress...In laboratory experiments that simulate doubled atmospheric CO₂ conditions, coral calcification rates decrease by 11–37%” (Buddemeier, *et al.*, 2004).

On the other hand, increasing temperature, as long as it is below the upper threshold limit, increases coral calcification rates from: 1) increased coral metabolism and 2) through photosynthesis by zooxanthellae. So far, growth of coral reef from increased temperatures has been greater than losses from increasing acidity.

“Field experiments (Halley & Yates, 2000 *In:* Buddemeier, *et al.*, 2004) indicate that the dissolution rate could equal the calcification rate once atmospheric CO₂ concentrations reach double the pre-industrial levels, (which would occur some time around 2050). This points to a slow-down or reversal of reef-building and the potential loss of reef structures in the future” (Buddemeier, *et al.*, 2004).

Similarly, Schleyer and Celliers (2002 *In:* Linden, *et al.*, 2002) conclude that

“a further build-up of the atmospheric CO₂ that is causing climate change is expected to reduce the marine aragonite²¹² saturation state globally, leading to a commensurate decline in reef formation

²¹² Aragonite is a mineral of calcium carbonate (CaCO₃) composing the skeletons of scleractinian reef-building corals

and the scleractinian (reef building corals) composition in coral communities”.

Wilkinson (2002) states that to date there has been no field evidence of corals having reduced calcification and growth rates from increased CO₂ concentrations in seawater, though research in Biosphere II, Arizona and in other mesocosm (enclosed chambers with controlled environments) studies demonstrates this possibility if atmospheric CO₂ concentrations continue increasing in the 21st century. It is predicted that coral reefs will not become extinct, but that humankind will witness reductions in coral cover and species diversity and economic value if these models are correct from global warming impacts including disease and bleaching. Furthermore, “the ‘resilience’ of a reef to withstand natural stress from cyclones or bleaching has decreased over the past 200 years under the negative impacts of over-fishing and pollution” (Wilkinson, 2002).

Goreau (2005) on the other hands states

“Acidification does reduce calcification, but the reefs will be dead from high temperatures long before this is significant. It is a red herring argument which distracts attention from the imminent dangers”.

8.10.2 Coral Diseases

Scientists are trying to find the causes behind a string of mysterious coral diseases with names like “White Pox”, “Black Band”, “White Band”, “Red Band”, “Yellow Band”, “Coral (white) Plague”, “Dark Spot” and “Rapid Wasting Syndrome”. The names of these diseases describe their visual appearance that divers observe on the surface of corals (e.g., a black or white circular band). Researchers do not yet know if these diseases are caused by viruses, bacteria or fungi, but they suspect that corals stressed by human activities such as pollution,

boat/anchor damage, episodic sediment loading, as well as physical damage by storms, destructive fishing methods and by large marine mammals make corals more susceptible to disease (Goreau, *et al.*, 1998, U.S, Dept of State, 1998d; 2001; Turner, 2002). Goreau, *et al.* (1998) do an excellent job of describing these diseases and the species of corals they attack, as well as diseases of sponges, coralline algae, sea urchin and sea fans. So far, only the Black Band and White Pox diseases appear to be strongly correlated with human sewage (Goreau, 2005).

“Black Band” disease. Goreau, *et al.*, (1998) found only “Black Band” disease to be strongly correlated with human pollution. Littler, *et al.* (1989) indicate that “Black Band” disease is the result of shallow reef-building coral being attacked by the blue-green algae, *Phormidium corallyticum*, called a cyanobacteria by Goreau, *et al.* (1998). A dense black band of these algae separates the live coral on one side and the dead coral on the other.

“Coral (white) Plague” disease. Two types, slow and fast (cm/day) affecting 18 species of non-Acroporid corals in Florida Keys (Goreau, *et al.*, 1998).

“Dark Spot” disease. Early stages dark spots (purple, maroon and brown in color) in the middle of the normal tissue that gradually dies back forming a ring/hallow surrounding dead tissue. *Siderastrea siderea* Caribbean coral most commonly attacked (Goreau, *et al.*, 1998).

“Rapid Wasting” syndrome. Attacks *Montastrea annularis* and *Colpophyllia natans* corals. Infected tissue often attacked by parrotfish resulting in deep excavation of skeleton (Goreau, *et al.*, 1998).

“Red Band” disease. Cyanobacteria *Oscillatoria spp.* (blue-green algae) impacting *Gorgonia ventalina* by forming a red mat (Goreau, *et al.*, 1998).

“White Band” disease. Also attacking *Acropora cervicornis*, “White Band” disease is what progressively destroyed elkhorn coral, *Acropora palmata* slowly from the base up in the late 1970s to early 1980s throughout the Caribbean (U.S. Dept. of State, 1998d; Goreau, *et al.*, 1998), eliminating up to 95% of the elkhorn and staghorn corals (genus *Acropora*) from some locations; these corals are the dominant reef-builders in shallow water (U.S. Dept. of State, 1998d).

“White Pox” disease. Causes round white spots up to 10 cm in diameter in bare tissue on *Acropora palmata* (Goreau, *et al.*, 1998). “White Pox” disease has also been shown to be associated with the sewage bacteria *Serratia marcescens* in Florida (Goreau, 2005).

“Yellow Band” disease. Cervino, Hayes, Polson, Polson, Goreau, Martinez and Smith (2004) found “Yellow Band” disease to be a bacteria that attacked primarily zooxanthellae in situ resulting in decreased photosynthesis, as opposed to causing bleaching and secondarily adversely impacting growth of *Montastrea spp.* and other corals, the increased incidence correlating with increased sea surface temperatures.

Most likely because of its current underdeveloped coastline, the coral reefs of the East African coast appear relatively free of disease, though this could change quite rapidly if coastal tourism takes off without the appropriate environmental controls in place. Buddemeier *et al.* (2004) point to studies that demonstrate a correlation with increasing ocean temperatures that create a more favorable environment and thus synergistically, along with other factors, increase the corals’ susceptibility to disease. Likewise, Goreau (2005) states,

“the bulk of these diseases are due to pathogens, not “stress” but increased temperature makes them worse. We have now identified

pathogens for around half a dozen coral, gorgonian, sponge, and algae diseases, but little good work has yet been done on the causes of these new diseases in terms of understanding how they have developed new pathogenic behavior in new habitats or how they spread”.

Once this symbiotic relationship between the zooxanthellae and coral polyp is destroyed, as indicated by coral bleaching (Rensberger, 1987; Roberts, 1987; 1988 all *In:* DeGeorges, 1990a), ultimately the coral becomes more vulnerable to disease (e.g., “White Band” and “Black Band” diseases that kill off corals, especially staghorn and elkhorn coral).

Although there is little evidence, many scientists feel that the regional dieback of sea urchins from a viral disease or the “White Band/Black Band” diseases attacking corals in the Caribbean are symptoms of a highly disturbed and pollution stressed ecosystem making the urchin weakened and vulnerable to disease (Ward, 1990; Shinn, 1989 *In:* DeGeorges, 1990a; Buddemeier, *et al.*, 2004). Wilkinson (2002; 2004) states that though evidence is limited, there is a nagging suspicion that many disease outbreaks are inadvertent results of human activity whether through pollution washing off the land, heat stress to corals or through over-fishing the organisms that can control plagues (Wilkinson, 2004). Once again, we come back to land-based pollution as a key determinant of these diseases.

Goreau (2004e) indicates that James Cervino, Ray Hayes and he have papers in press-relating temperature (global warming) and sewage effects on a consortium of four bacteria causing the most widespread coral diseases in the Caribbean. What

“has mistakenly been called bacterial ‘bleaching’ is in fact a bacterial disease of the algae that operates by completely different cellular mechanisms. There are strong temperature interactions that

speed up disease, making disease too easy to confuse with bleaching, and vice versa. But many of these bacteria are land derived pathogens linked with human sewage".

"Diseases of scleractinian or stony corals have increased significantly over the last decade and are causing widespread mortality of important reef-building species. Studies have shown that coral diseases are affecting greater numbers of coral species, are increasing in frequency and distribution, and are spreading to new regions faster than ever recorded in the past. In recent years, there has been an emergence of newly described coral diseases with new types of pathologies or tissue conditions not observed in the past. Several of these diseases also have been recorded as killing coral tissue at rates much faster than ever observed. Coral diseases occur in response to biotic and abiotic stresses. Biotic stresses are instigated by microorganisms including bacteria, fungi, viruses, and protozoans. Abiotic stresses occur in response to physical or chemical stresses, such as increased sea surface temperatures and UV radiation, anthropogenic input of nutrients, sediment, and other pollutants. Abiotic stresses may exacerbate the role of microorganisms in disease processes. Thus, the recent emergence of disease in corals is believed to be a consequence of deteriorating water quality that favors the proliferation of microorganisms, or of a reduced ability of a coral to defend itself against biotic and abiotic stresses. Most diseases appear to be a response to multiple factors" (U.S. Dept. of State, 1998d).

"The recent emergence of multiple diseases and the rapid spread of these afflictions suggest both that the corals have lost the capacity to protect themselves and that the pathogens have adopted novel strategies or have acquired enhanced virulence in the coastal marine environment. It is possible that combined stresses resulting from repetitive episodes of bleaching, exposure to pollution, etc., might account for the increased incidence of diseases of reef organisms now being reported especially in the relatively confined Caribbean region" (Hayes & Goreau, 1997).

"Although coral diseases are damaging reefs around the world, they have been documented most frequently in the Western Atlantic, which suffers significantly from land-based pollution...Coral diseases are also having an impact on other important reef-building corals worldwide, but assessments in regions other than the western Atlantic are limited to a few reefs" (U.S. Dept. of State, 1998d).

Addressing the problem requires several actions (U.S. Dept. of State, 1998d):

- Identification of the causes of diseases, including the role of microorganisms and the relationship of biotic and abiotic stressors;
- Development of standardized terminology to describe and characterize coral diseases;
- Identification of the global distribution of coral diseases, species affected, abundance of diseases and the impact of disease on coral reef structure and function;
- Identification of the natural level of coral diseases to understand whether disease occurrence is being exacerbated by controllable stresses; and
- Development of strategies to mitigate coral diseases.

Because the cause-effects relationships between natural disease-causing organisms and anthropogenic stressors, acting alone or in tandem are largely unknown, the U.S. Coral Reef Task Force (CRTF) will establish a Coral Disease Consortium focused specifically on coral health (U.S. Coral Reef Task Force, 2000).

“If rising temperatures and sea levels were not enough, ocean life is also reeling from other human caused global changes: the over-harvesting that has brought every fishery to the brink of collapse, the proliferation of exotic species, the uncontrolled flood of mud, sewage, fertilizers, garbage, and chemicals that are choking marine life, and now raging epidemics of exotic new diseases that are wiping out one population after another like marine AIDS. Some of these diseases are caused by bacteria, some by fungi, some by viruses, but most remain unknown, yet all seem from their patterns of proliferation to have origins from land, and seem to have been caused by yet unknown interactions between pollutants and

mutations caused by chemicals or selected for in response to them”
(Goreau, 2002).

8.10.3 Invasive Species Introduction

Introductions of invasive species are also of serious concern in some areas, particularly through the discharge of ballast water from visiting vessels that can transport alien species from one region to another (Evans, 2002).

8.10.4 Coral and the Aquarium Trade

“The unsustainable commercial extraction of corals for aquarium and ornamental specimens, jewelry, and construction materials is joining other threats as cause for concern to the biodiversity, structure, and function of coral reef ecosystems. Extraction of corals for curios, jewelry, and the aquarium trade is driven by international demand, with most collection occurring in the Indo-Pacific and most exports going to the United States and Japan. Concern about overexploitation has led the Convention on International Trade in Endangered Species (CITES) of Wild Fauna and Flora to list most coral species in trade on CITES Appendix II, which requires that exporters file trade records including information on the exporting country, taxa, and amount. Pink, gold, and bamboo corals are not currently listed in CITES” (U.S. Dept. of State, 1998e).

“Coral extraction for aquarium and curio trade involves hard corals in the Orders *Coenothecalia* (blue coral), *Milleporina* (fire coral), *Scleractinia* (stony corals), *Stolonifera* (organ pipe corals) and *Styleasterina* (lace corals). Ornamental corals are species with ornate skeletal structures and include the fast-growing, branching corals like *Acropora* and *Pocillopora*. Live corals are primarily large-polyp specimens such as *Euphyllia*, *Goniopora*, *Catalaphyllia*, *Plerogyra*, and *Trachyphyllia*; these corals grow very slowly, have low rates of sexual recruitment, require many years to reach sexual maturity, and include rare and threatened species. Coral for jewelry -- black corals (Order *Antipatharia*) and precious corals (pink, gold, and bamboo corals) -- are deepwater species that occur at very low densities, are recruitment-limited,

and grow very slowly. Precious corals are generally extracted using destructive trawls and tangle-net dredges. Commercial extraction of corals has damaged essential reef habitats and is believed to be causing local depletions of rare species in some areas" (U.S. Dept. of State, 1998e).

"For over three decades, the Philippines was the major supplier of ornamental corals for the international market. A ban on coral exports from the Philippines caused a shift in the export markets, with Indonesia emerging as the largest supplier in the 1990s. Since 1995, coral exports from Fiji, Mozambique, Taiwan, and Tonga have steadily increased; 64 other nations also export live and dead coral. In 1996, coral exports listed in the CITES Trade Database consisted of over 2.5 million pieces of live coral, 670,000 kg of raw coral, and 31,000 colonies of black coral from 114 genera and 181 identified species. Over 90% of the live coral is imported into the United States, and most raw coral is imported into the United States and Japan. Less than 0.02% of all exports are captive-bred corals" (U.S. Dept. of State, 1998e).

The United States imports nearly half of the total worldwide-trade in aquarium fishes, with approximately 67% (two-thirds) originating in the Indo-Pacific. From 15 to 20 million coral reef fishes are traded each year. A 1997 survey of U.S. retailers found that as many as 33-50% of the aquarium fishes imported from Southeast Asia die shortly after arrival. Almost all the aquarium fish are collected using cyanide. Cyanide kills corals at concentrations (50-600 mg/l CN⁻) lower than used by fish collectors (1,500-120,000 mg/l CN⁻) (Cervino, Hayes, Honovich, Goreau, Jones & Rubec, 2003; Goreau, 2005). Improvements in transportation, handling and husbandry of live coral reef species for the marine aquarium trade may also be needed to reduce mortality rates (U.S. Coral Reef Task Force, 2000). Addressing the problem requires several actions and associated capacity building (U.S. Dept. of State, 1998e):

- Identification of coral species involved in the trade and tracking the trade.
- Enforcement of existing laws and regulations;
- Monitoring of harvesting impacts on both shallow and deep reefs;

- Development of alternatives to the wild harvest of corals -- in this respect, recent work on aquaculture of live corals for the aquarium trade appears promising; and
- Development of education programs for consumers on the impact of coral harvesting and possible alternatives.

8.10.5 Sea Urchin Dieback

See Section 8.3.1, Sea Urchin Dieback.

8.10.6 Over-fishing of algal grazers

See Section 8.3.2, Over-Fishing of Algal Grazers.

8.10.7 Boat and Diver Damage

In the Florida Keys, techniques have been developed for permanent moorings at which dive boats are tied off, without dropping anchors. In some cases, the group dives with a dive leader as a unit and the dive boat follows the divers' bubbles or a diver towed buoy, as opposed to dropping anchor or tying off to a permanent mooring. SCUBA divers are among the worst culprits of physical coral damage, especially underwater photographers who tend to stand, lie and sit on the coral, anything to get a shot. Divers need to be educated to not touch or brush up against the coral. The dive master needs to lecture and then be prepared to take action if one of the divers breaks the rules of good conduct that have been laid down. With the establishment of management plans for marine parks, the impacts of tourism (e.g. anchor/diver damage, souvenir collecting, commercial exploitation) should be minimized (DeGeorges, 1990a). Although important to address, it is the principal author's belief, based on what he has observed and based on a minimal amount of quantitative data that these issues cannot compare

to the pressing need to address the damage caused to coral reefs associated with land-based pollution and now global warming.

8.10.8 Sewage Associated with Sailboats and Yachts

In the USA, live-aboard boats must have holding tanks for sewage. This sewage must be dumped in the open sea and/or in harbors where pump-out facilities exist. The pump-out facilities pipe the sewage to wastewater treatment plants. In the Caribbean and in much of the developing world, laws requiring holding tanks and pump-out facilities do not exist. Most live-aboard recreational vessels turn the “holding tank area” into an extra supply of fresh drinking water. Sewage is discharged directly into the sea. The best example of degraded reef as a result of sewage discharge from recreational boats was observed in the Tobago Keys where up to 140 boats a day anchor over the coral reef. It is supposed that Africa has a similar problem, though it is unlikely, other than in a few isolated harbors, that there are enough live-aboard sail boats for this to be a concern at present, though this may change as tourism develops (DeGeorges, 1990a).

8.11 COASTAL DEGRADATION EAST AFRICA AND SOUTHWESTERN INDIAN OCEAN

The distribution of coral reefs off Africa amount to about 7% of the global coral reefs or 19,901 km² (7,684 mi²) (Spalding, *et al.*, 2001). In East Africa,

“total mangrove area is about 600,000-1,200,000 ha, and distribution is correlated with coastal indentation and large river discharge. Over-exploitation and the lack of expertise and institutional management capacity threaten their existence. Seagrass beds are found throughout the region and are under pressure from intensive use of bottom traps and beach seines, explosives fishing, sand mining and dredging” (Jameson, McManus & Spalding, 1995).

The majority of colonial coral reefs are found off the East Coast of Africa and associated islands from the Red Sea to Sodwana Bay, South Africa.

8.11.1 Coral Degradation off East Africa

Over-exploitation of fishery resources has been reported from Tanzania and Mauritius; and reefs off Kenya, Tanzania, and Mauritius suffer from destructive fishing practices (e.g., dynamiting). Trampling of coral by fishermen has also degraded reefs in the region (observed by principal author off Kalifi, Kenya). Coral and coral sand mining in Mafia (Tanzania), Comoros, Mauritius, and Madagascar have damaged reefs. Over 500,000 tons of coral sand is excavated annually from Mauritius, and sand mining has scarred most beaches in the Comoros. Over 250 tons of shells and corals (aquarium trade) were exported from Tanzania in 1974. Exploitive collection has moved from the depleted areas off Tanzania and Kenya to the islands of Zanzibar and Mafia. Sedimentation from agricultural practices is a major problem throughout the region. The problem is critical in the Comoros and has also affected reefs off the Seychelles, Dar es Salaam, and Zanzibar. Eutrophication (nutrient pollution) is a problem in Port Louise, Dar es Salaam, and Zanzibar (Jameson, *et al.*, 1995).

The degradation of the Athi River watershed in Kenya has significantly increased since 1961, destroying large areas of coral reef around the Malindi Reef complex (Dubois, Berry & Ford, 1985 *In:* DeGeorges, 1990a). Obura (2002 *In:* Linden, *et al.*, 2002) notes:

- Over-fishing and destructive fishing (dynamiting, poisoning, small-mesh seines, over-harvesting fish and shellfish), pollution, mining, deforestation and poor land management and poorly managed and planned tourism are

the major localized stresses damaging coral reefs on the East African Coast;

- From December 2001-February 2002, what appear to be red tides [*Karenia mikimotoi* (formerly variously known as *Gymnodinium nagasakiense*) and *G. aureolum*] were observed off Somalia, Kenya, Tanzania, Oman and Yemen, apparently from stronger than normal upwelling and strong onshore currents;
- Shortly after the red tide, an unknown coral disease primarily impacted the genera *Montipora*, *Astreopora* and *Echinopora*, in some areas causing near 100% mortality, but also *Pocillopora*, *Acropora* and *Platygyra*. The disease was identified by electron microscopy as a fungus; and
- In Mozambique, reefs affected by bleaching were exposed to increased sediment loading from February-May 2001 from floods in southern Mozambique. In the Xai-Xai lagoon, remaining coral cover decreased from 20 and 5% to 10 and 0.5% respectively for hard and soft with minimal recovery by December 2001. This effect rivaled the impact of the El Niño at this latitude, and reversed recovery on reefs affected by the El Niño. Floods in 2007 and 2008 will like add to this problem (see Chapter 7, Section 7.9.7.3, Zambezi River Floodplains, Cahora Bassa and Kariba Dams, Zambezi Delta, Mozambique).

Goreau (2005) states,

“the fungus is probably an opportunistic infection rather than a causative parasite. I think this disease, which is still poorly understood microbiologically, is now world wide in extent, and there are few places now that I don’t see it”.

Wilkinson (2002) estimates that coral reef impacts in the Xai-Xai lagoon as a result of flooding were respectively declines of 60% and 95% of hard and soft coral that made up 19% and 5% reef cover prior to flooding with minimal

recovery in 2001. More detail is provided in various reports contained in Linden, *et al.* (2002).

“The UNEP Eastern African Coastal and Marine Environment Resources Database and Atlas Project is producing a GIS covering East Africa and western Indian Ocean Islands. Several marine reserves were designated in Tanzania, but exist on paper only, and a recent addition off Zanzibar (gazetted in December 1994) is under private management. Two reserves exist in Mozambique (Bazaruto National Park and Inhaca Island Marine Reserve). Several areas have been designated around Mahé, the Seychelles and adjacent islands. Aldabra (the Seychelles) is a World Heritage Site. A few areas have been recommended for protection around Mauritius. Reefs are also protected in the Flacq and Black River fishing reserves. Four coral reef marine parks and five marine reserves exist and are well managed in Kenyan waters, and have been useful in showing the decline of species in non-protected areas” (Jameson, *et al.*, 1995).

8.11.2 Coral Degradation, Western Indian Ocean

The Indian Ocean Islands Global International Waters Assessment (GIWA) (Payet, *et al.*, 2003) found pollution (both sewage and solid waste), followed by global change (e.g., global warming) to be the most significant concern for the Indian Ocean islands region comprising the island states of Comoros, Mauritius, Madagascar and the Seychelles situated in the western Indian Ocean (WIO) region. Tourism and fisheries are likely to be the most significant economic sectors in the next 20 years and their growth could be jeopardized by eutrophication from sewage associated with development, misuse of fertilizers, intensive animal husbandry, industrialization and coral bleaching die-off from global warming. Factors such as population growth and increased consumption, which can take years to redress, can be considered an absolute root cause. The root causes identified by the GIWA survey identified for solid waste pollution,

and which can also be applied to land-based pollution in general that must be addressed, are:

- Root cause 1: Lack of investment planning and priorities;
- Root cause 2: Lack of effective mechanisms, inadequate institutional structure, laws and capacity;
- Root cause 3: Lack of adequate facilities, services for collection and management of wastes; and
- Root cause 4: Lack of education and awareness.

Coral reefs in the southwestern Indian Ocean islands are severely stressed as a result of human activities, compounded by the recent effects of the 1998 Indian Ocean bleaching event. A recent global survey (Bryant *et al.*, 1998), indicates that at least 25% of the coral reefs in the region were at high risk of degradation from human activities (mainly within the Comoros area), 28% at medium risk (mainly within the Madagascar and Mauritius areas) and 47% at low risk (mainly within the Seychelles area) (Also, see Table 8.3).

Goreau (2005) states that “these ‘risk’ estimates are based on arm waving about stresses, not on real measurements. Most of the corals in this region were killed by global warming in 1998, so these low ‘risk’ sites are nonsense”.

8.12 SUMMARY - PERSONAL OBSERVATIONS OF CORAL REEF DEGRADATION IN AFRICA

The following are observations the principal author made during his official duty for USAID as its regional environmental advisor for East and Southern Africa and on other occasions as his work led him along Africa’s coastal areas over the past 15 years.

It should be noted that land-based pollution and within this category improperly treated sewage is a major issue where large populations inhabit coastal areas. This will be a growing problem as these areas are developed for tourism and as people flee over-populated rural areas.

8.12.1 Land-Based Pollution and Coral Reef Degradation Mahé, the Seychelles

Observations were made of the heavy cover of *Sargassum spp.* algae smothering the nearshore fringing corals of Mahé, the Seychelles (Table 8.12), and epiphytic algae beginning to fill in spaces between the horny projections of the *Acropora/Porites* corals at the two sites on St Anne Marine National Park, an island a couple of kilometers off Mahé, the Seychelles. This could be indicative of nutrient pollution associated with improperly treated and disposed waste between Victoria (capital of Mahé) and the airport on Mahé. For instance, from the permanent resident population of Victoria alone (23,000 people), it can be estimated that this is equivalent to fertilizing the nearshore coastal waters with 17,300 – 17,700 kg (38-39,000 fifty pound bags) of 20/10/10 (NPK)/year fertilizer as a result of human waste disposal. If all of these nutrients are available for algae production, depending on the limiting nutrient, between 3.6 and 6.4 million kg (8-14 million pounds) dry weight of algae could be produced per year in Victoria's nearshore coastal waters. Looked at in this light, it is no wonder that epiphytic algae could out-compete and over-grow corals that have evolved to rapidly recycle nutrients in nutrient poor tropical waters. The importance of monitoring for nutrient pollution cannot be overstated. If siltation is the major cause of degradation, there is no quantitative data to determine what has been more devastating, sediment from dredging activities or sediment from land runoff during heavy storms (DeGeorges, 1990b).

Table 8.12: Underwater survey observation, Mahé and St Anne marine park, the Seychelles

SITE	OBSERVATIONS
<u>Baie Tourney National Park</u> , near lighthouse at mouth, Site 1 as example of minimally impacted reef	Large granite boulders dominated by different species of <i>Acropora spp.</i> 100% live coral cover, excellent diversity of fish, maximum depth 15 m (50 feet), 15 minutes, visibility 30.5 m (100 feet)
<u>Baie Tourney National Park</u> , 1 km off of National Youth Service camp, Site 2 as example of minimally impacted reef	Coral Reef showing minimal signs of stress with 20-30% dead coral, most likely caused due to pollution coming from NYS camp that has been in existence for about ten years, 3.7 m (12 feet) depth, 20 minutes, water quality data needed to better understand cause of reef degradation, visibility 15-30.5 m (50-100 feet)
<u>Auberge Club De Seychelles</u> 100 meters off shore, Site 3 as example of minimally impacted reef	Coral reef in excellent condition, 5% dead coral, minimal negative impact from hotel, perennial river in populated watershed, maximum depth 5.5 m (18 feet), 15 minutes, visibility 15-30.5 m (50-100 feet)
<u>One kilometer offshore from Victoria Sewage Treatment Plant</u> , in vicinity of outfall, Site 4 as example of highly degraded coral reefs from which fill material will be collected	95% of coral on fringing reef dead covered in <i>Sargassum spp.</i> , remaining dominant coral "boulder like", appears to be species of <i>Porites spp.</i> , minimal sedimentation observed on coral although visibility only about 3 feet, water column full of colloidal material and suspended solids, water quality data needed to better understand, maximum depth 2.4 m (8 feet), 15 minutes

Source: DeGeorges (1990b)

Table 8.12 (Cont.): Underwater survey observation, Mahé and St Anne marine park, the Seychelles

SITE	OBSERVATIONS
<u>Brilliant Point</u> , off lagoon outlet, just off of and before Runway Lights, Site 5 as example of highly degraded coral reefs from which fill material will be collected	40% <i>Sargassum spp.</i> cover, 40% silt covered dead coral and 10-15% live coral, dominated by same coral species as off sewage plant, visibility same as off sewage treatment plant, maximum depth 3 m (10 feet), 15 minutes
<u>Ile Cachée</u> , Site 6 as example of coral reefs that may have been impacted from dredging activities <u>(St. Anne National Marine Park)</u>	70% live coral, 30% dead coral. <i>Acropora spp.</i> corals dominant, most of dead coral on top of reef where <i>Turbinaria spp.</i> algae begin to dominate and percent dead coral increases, most of reef slopes living, while coral appears mostly alive, beginning to see epiphytic algae growing in interstitial areas, this could be the beginning of reef degeneration, reef needs monitoring both biologically and water quality, fish life excellent, visibility 15-30.5 m (50-100 feet)
<u>Ile Moyenne, St. Anne Channel</u> Site 7 as example of coral reefs that may have been impacted from dredging activities <u>(St. Anne National Marine Park)</u>	Exact conditions difficult to generalize, slopes, dropping off to a sandy bottom at about 12.2 m (40 feet) of depth, are made up of coral talus, at shallower depths 3-4.6 m (10-15 feet) and shallower area dominated by coral, <i>Acropora spp.</i> , while coral appears mostly alive, beginning to see epiphytic algae growing in interstitial areas, this could be the beginning of reef degeneration, reef needs monitoring both biologically and water quality, shallows (5 feet depth and less) dominated by extensive beds of <i>Turbinaria spp.</i> , algae, fish life excellent, visibility 15-30.5 m (50-100 feet)

Source: DeGeorges (1990b)

The above observations are speculative and a water quality and reef-monitoring program were recommended. Goreau (2005) states,

“the Porites and Sargassum remain in front of Victoria. Almost all the corals at Baie Ternay died in 1998, and the Marine Park Authority had to close the snorkel trail near Moyenne and Ronde because almost all the corals died. I found severe coral mortality in

the Amirantes too, despite lack of local anthropogenic stress, except at a few points where there was localized upwelling of cold water. Most of the corals on the remote Saya de Malha Banks died, even though they are very far from any stress, and we are the only people to have dived on them before and after bleaching”.

This implies that many corals died from bleaching associated with global warming.

It was expected that many of the 114 outer islands in the Seychelles contain virgin coral reef habitat. Not only because of their importance with regard to biological diversity, but because of their importance to island ecology, fishing and tourism, the Seychelles has the unique opportunity to protect its reefs based on its philosophy of sustainable development. These observations are supported by Ahamada, *et al.* (2002 *In:* Wilkinson, 2002) who state that on the islands of Comoros, Madagascar, Mauritius, Reunion and the Seychelles, reefs near large landmasses show obvious signs of degradation, whereas many of the isolated reefs remain in good condition.

However, by 2004, Ahamada, *et al.* (2004 *In:* Wilkinson, 2004) also found on the “inner islands” of the Seychelles that

“there was an average of 10.2% live hard coral cover on the 48 reef sites surveyed in early 2004. This shows moderate levels of recovery (from coral bleaching in 1998) from only 3% mean coral cover in November 2000 at 22 sites. The coral recovery has been steady, with statistically significant increases every year since 2000”.

On the “southern atolls” of the Seychelles in

“May 2003, live coral cover around Aldabra Atoll ranged from 3% to 58% in shallow water, with the very low values shallower than 10 m depth. Below 10 m depth, cover improved, though

Acroporids were low at all depths. Cover varied from 0.4% to 52% in deeper water, with total coral cover (soft and hard corals combined) increasing substantially over 4 years at 4 shallow-water sites and 2 deep-water sites. The increase in mean of total live coral cover at all sites between November 1999 and May 2003 was 11.7% in shallow water, and 4.9% in deep water; giving an annual increase of 3.3% and 1.4% respectively. The hard coral component in shallow water was 0.3%, but in deep water there was a decrease of 1.4%...The changes in coral cover were dominated by soft corals, especially the genus *Rhytisma* which forms an encrusting mat 2 - 4 mm thick. Dead coral cover and algal cover have barely changed, except that there has been a considerable increase in coralline algae, especially in shallow water" (Ahamada, *et al.*, 2004 *In:* Wilkinson, 2004).

Based on what was happening to the world's tropical coastal zones, the principal author believed back in the early 1990s that these islands (other than the over-developed Mahé) may be some of the few areas left in the world where healthy stands of coral reef exist over such a large area. The 1998 bleaching event may have changed much of this.

It should be noted that the identification of Indian Ocean corals is very difficult due to polymorphism. That is to say that under different environmental conditions, the same species of coral can take on a number of different forms. Through a combination of underwater photography of live coral and bleached samples of the photographed coral, a reference collection can be established to aid in the development of a monitoring program (DeGeorges, 1990b). Goreau (2005) also believes many *Acropora spp.* may actually be hybrids, making them difficult to classify. "In the Indo-Pacific where hundreds of *Acropora spp.* may spawn simultaneously, the chances of hybrids are vastly greater, and this may well account for the confusion over their taxonomy" (Goreau, 2005). This hybridization process in corals is described by Vollmer and Palumbi (2002).

Ahamada, *et al.* (2002 *In:* Wilkinson, 2002) identify deforestation and poor agricultural practices causing major soil erosion as an issue around Victoria and St. Anne Marine Park (20,000 visitors/year). The Seychelles, along with Mauritius, now require adequate treatment of solid wastes and sewage, Reunion being the only island in the region with sewage treatment facilities. While Victoria, Mahé, has a sewage treatment plant, DeGeorges (1990b) notes that treatment was inadequate to significantly remove nutrients. According to Ahamada, *et al.* (2002 *In:* Wilkinson, 2002), a new treatment plant became operational in 2001, though nothing is indicated as to the level of treatment or placement of the outfall.

8.12.2 Other Personal Observations on the State of Coral Reefs Off Africa

The following summarizes observations made by the principal author off the coast of Africa as to the state of coral reefs (Table 8.13).

Ahamada, *et al.* (2002 *In:* Wilkinson, 2002) state that coral reefs along the tourist coast of Mauritius continue to be degraded by sediment and nutrients from agricultural runoff. Sugar cane occupies 45% of the land in Mauritius (U.S. Library of Congress, 2003) and, as in the Caribbean, runoff from these lands pollutes the sea with fertilizers, pesticides and sediment. In addition, gray and wash water from the 700,000 annual tourists plus the 1.2 million local population, making this one of the most densely populated countries in the region (Ahamada, *et al.*, 2004 *In:* Wilkinson, 2004), is likely having a major impact on nearshore water quality.

Table 8.13: Other personal observations of principal author off African coast

SITE	OBSERVATIONS
Dakar, Senegal, 1977-1998	Shallows rocky shoreline as opposed to hermatypic (colonial) corals (no colonial corals!), from about 12-31 meters (40-100 feet) ahermatypic (non-colonial corals) yellow gorgonian finger corals, fish life rich, nutrient rich from upwelling and raw sewage from Dakar – many places are unsafe to swim
Old Town, Zanzibar 1990	In general coral reef and fish life appear healthy – about 1 km offshore fringing island, some reef near port and new tourism hotels beginning to show signs of algal cover
Kalifi, Kenya, 1991	Coral reefs below sisal plant discharge dead and smothered with sediment from plant effluent, a few kilometers further up coast with low density tourism homes – corals healthy, though at low tide, local fishermen walk on shallower coral reef to catch fish
Ras Mohammed National Park, Red Sea Egypt, December 1991	Corals healthy, no development allowed in park
Sharmel Shiek, Red Sea, Egypt, December 1991	Watershed completely built out with tourism facilities, daily Lufthansa flight, corals mostly dead with high algal cover – indicating likelihood of heavy nutrient pollution
Blue Hole, Dahab, Israel, December 1991	In middle of desert, coral health excellent, volcanic funnel, with exit hole at 56 m (185 feet) depth, plaques of people who died missing tunnel
Diego Suarez, Madagascar, Off Military Base 1991	Excellent coral health – only able to snorkel nearshore
Source: Principal Author	

Table 8.13 (Cont.): Other personal observations of principal author off African coast

SITE	OBSERVATIONS
Ile De Maurice (Mauritius) Grand Baie Aquarium October 21, 1990 NW/N Coast	The coral reef was highly degraded, mostly algal covered and dead (95-98%); it must be one of the better reefs since the dive operator wanted to make it into a marine park. Mauritius is built out with hotels and is covered in sugar cane and some tea. There is also industry. It is supposed to have one of the highest rates of pesticide application/km ² anywhere in the world. Also, according to the dive operator, there is lots of runoff during the rainy season. This reminds me of what I have been seeing in the Caribbean, likelihood of heavy nutrient, sedimentation and pesticide pollution.
Big T and Fern Reefs, 45 minutes up coast from Dar es Salaam, Tanzania, off Sea Breeze Hotel, December 1997. 5 Dives	Coral healthy, best coral 17-meter depth, high fish diversity
Pemba, Mozambique, March/April and Dec.1998, four dives off Nautilus Hotel	Pemba has a human population of 88,000 with no sewage. People defecate on the beach as they did all along the coast of Cabo Delgado Province, high algal cover in shallows and on wall, entire reef dived appears nutrient stressed as would be expected, on April 4 th dive observe lots of dead and bleached corals in shallows, also problems of local fishermen dragging nets in shallows, further up coast as near Tanzania border dynamiting said to be a problem.
Baixo Danae (Shallow Place) 1990, 50 km (31 mi.) off of Maputo and 10 km (6.2 mi.) N/NW off Inhaca Island, 1990 with South Africans (Dr. Kruger and Bush Terre Blanche of the South African Embassy).	Fish life excellent, reef beginning at about 7.6-9.1 m (25-30 feet) in depth. Looks physically damaged possibly from either dynamiting or trawlers dragging nets with about 40% live coral.
Inhaca Island, off Maputo, Mozambique, 1990	Visibility low, high algal cover on reefs – signs of pollution from capital city
Source: Principal Author	

8.13 THE FAILURE OF MARINE PARKS IN THE CARIBBEAN TO ADDRESS BIODIVERSITY ISSUES AND THE REAL CAUSES OF CORAL REEF DEGRADATION – LESSONS FOR AFRICA

While he was working as an environmental advisor for the Caribbean, the principal author had the opportunity to visit, dive and photographically record the following marine parks/reserves (marine protected areas/MPAs):

- Holchan Marine Park, Ambergris Bay, Belize, started by Wildlife Conservation Society (WCS);
- Lighthouse Reef/Blue Hole, Belize;
- Les Arcadins, Haiti, WWF;
- Montego Bay, Jamaica, The Nature Conservancy (TNC); and
- Anse Chastinet/Pitons, St. Lucia

The flaw behind all of these marine parks is:

- They took a simplistic approach, declared an area a park, put buoys around it, declared it off limits to local fishermen; and
- All of these marine parks, except Anse Chastinet, were in watersheds with land-based pollution problems (Table 8.6), even Lighthouse Reef/Blue Hole many miles offshore. On Lighthouse Reef/Blue Hole, pollution is believed to have been caused by, among others, a phosphate fertilizer ship that had run aground and from which the fertilizer was never removed, plus possible major changes in land use from Honduras to Belize (unfortunately, no water quality data available to verify) (see Section 8.5.1, Belize and Land-Based Pollution, Lessons for Africa).

When the principal author dived what is now Holchan Marine Park in 1973/74, Ambergris Cay was a sleepy fishing village of lobster divers. When he came back in 1988/89, the island was build out with fancy hotels and the mangrove and grass bed areas on the landward side of the island were being heavily dredged and filled for additional hotels and marinas.²¹³ An ecological disaster was underway. Excitedly, he went out to dive what had been virgin pristine coral reef in the mid-1970s only to find most of the barrier reef dead. The sport divers with whom he dived had no reference point. To them, fish swimming around dead coral was “beautiful”. The case of Montego Bay Marine Park is discussed above (Section 8.6.2., Montego Bay, Marine Park or Cemetery? A Lesson for Africa). Anse Chastinet/Pitons was the one underwater park that was pristine, largely because the entire watershed was a protected rainforest with minimal human inhabitants. It can only be hoped that this is still the case today. The principal author would never consider taking a vacation to dive on these “dead reefs”. About 20 years have gone by since the principal author dived these areas. He can only assume that environmental conditions have worsened.

The UNEP-WCMC World Atlas of Coral Reefs (Spalding, *et al.*, 2001) further supports the principal author’s concern. The atlas maps the 660 marine protected areas worldwide that incorporate coral reefs. It notes that, unfortunately, many of the protected areas exist on paper only, that they are poorly managed and have little or no support or enforcement. It says they often only focus on controlling the direct impacts of humans on coral reefs, ignoring the more remote sources of threats to reefs, notably pollution and sedimentation from the adjacent land. “Often remote from reefs, deforestation, urban development and intensive agriculture are now producing vast quantities of sediments and pollutants which are pouring into the sea and rapidly degrading coral reefs in close proximity to

²¹³ Estimated equivalent of 6,500 fifty pound sacks of 20/10/10 (N/P/K) fertilizer produced by tourists and residents from sewage dumped into nearshore waters of Ambergris Cay and Cay Caulker (DeGeorges, 1989b; 1990a).

many shores" (Spalding, *et al.*, 2001). Wilkinson (2004) notes that only 6% of 285 MPAs in the Caribbean are effectively managed. On the positive side, "no-take MPAs", that is protection zones where no harvest of resources are permitted, seem to help serve as a core to allow fish proliferation that feeds into buffer areas that are fished (Wilkinson, 2004) similar to parks in Africa that feed peripheral hunting blocks.

8.14 THE NEED TO WORK WITH FISHER COMMUNITIES TO MANAGE THEIR COASTAL ZONES

Too often fishermen are blamed for the demise of the world's coral reefs, when they are victims rather than culprits (see Section 8.3.3, Caribbean Fishermen Victims Or Culprit – Lessons For Africa). Where over-fishing is a problem, fishes are renewable resources and, if properly managed, can recover and provide a sustainable livelihood and source of food for populations. Implementation of the FAO Code of Conduct for Responsible Fishing by all states is a key step. Several management approaches, especially in combination, have shown promise (U.S. Dept. of State, 1998f):

- Institution and enforcement of bans on destructive fishing techniques [e.g., blast fishing, *muro ami* (destructive drive-in cone-shaped net with wings where divers scare/push reef fish into net) and cyanide fishing] and certain gear types (e.g., certain types of gill nets or mesh sizes) are a necessary first step and can be combined with traditional management practices such as seasonal closures or size and take limits;
- Community-based tenure and management of nearshore coral-reef fishery resources can give fishing communities incentives for long-term sustainable use;

- Development of "no-take" fishery reserves has shown particular promise in the Caribbean (e.g., Belize and the Bahamas) and the Indo-Pacific (e.g., Australia and the Philippines). Small-scale efforts can protect reef fishes and their habitat, making them more attractive to tourists and providing spillover benefits to surrounding fisheries. Larger protected areas can provide sources of larvae for whole regions. The U.S. just announced development of its first "no-take" coral reef fishery reserve in the U.S. Virgin Islands; and
- Linking protected areas and fishery reserves on a regional basis is necessary, since the fishery resources of most countries depend on larval recruitment from distant parent populations, often in other countries. The Caribbean offers a particularly important opportunity for implementing this approach.

For any of this to work, local communities, especially fishers, must be a key component of a bottom-up decision-making process undertaken to assure the viability of artisanal reef fisheries, unlike the process leading to the creation of the Montego Bay Marine Park, which initially excluded fishermen from decision-making. It appears the local fishermen revolted against this declaration and marched on the marine park headquarters, soon after the park was declared. Currently, only a small portion of the park, the Bogue Lagoon (a fish sanctuary) is off limits, with no spear fishing being the only gear restriction for the remainder of the park. Enforcement is lax and management limited, both due to a lack of manpower (*Zane, pers. comm.*).

Thus, it must be asked, who is the culprit and who is the victim? Is it the fishermen who are the primary cause of the problem, or inappropriate land-based development, resulting in pollution that destroys the fishing habitat that has supported communities for 100s of years? Yes, the fisherman is part of the

problem, but more often, he is a victim rather than a culprit. As human populations grow, just like on land, pressures on the fishery resources are increasing, and fishermen need to go from extensive into intensive management systems. Consideration should be given to dividing the East Africa Coast into management zones controlled by fisher communities. Youth from these communities need to be sent off for additional education in fishery and marine management. However, to kick fishermen off traditional areas so that hotel and dive operators can benefit to their exclusion or to create marine parks, comparable to game reserves on land, that result in the impoverishment, malnourishment and ultimately alienation of local people is both conservation folly, as it is doomed to fail in the long-term and is a violation of basic human rights, something which society should not tolerate.

Wilkinson (2004) explains that similar to what happened and is happening all over Sub-Saharan Africa in the creation of “Open Access Resources” (see Chapter 3, Section 3.4.1, Centralized Control of Natural Resources and The Arrival of Conservation),

“A contributing factor has (been) the replacement of traditional resource management, with ‘Western’ or ‘modern’ methods of governance. The traditional management approach was consensus based or ‘integrated coastal management’, often with the whole community involved in prior discussions before decisions were made that could affect the natural resources of the community; the resources were the property of the community. The Western model introduced a cash economy, the concept of free access to all marine areas, and a sectoral government approach, with a fisheries department to maximize fish harvest, a forestry department to maximize returns from trees, and the environment department tasked with conserving both resources and the whole ecosystem, but provided with few resources and staff”.

Given the victimization of coastal fisher communities globally the International Civil Society Marine, Inland Fisheries and Coastal Commission Declaration to the World Summit on Sustainable Development (WSSD) at NASREC, Johannesburg, 29 August 2002 (Edited: 12 November 2002) calls on all government decision-makers and other participants involved in bilateral and multilateral fisheries and oceans negotiations to (WSSD, 2002):

- “Transform existing systems of unequal ownership, access to and use of marine and coastal resources into systems based on sustainable and equitable use and access rights;
- Eradicate poverty and ensure food security for coastal communities through equitable and sustainable community based natural resource use and management;
- Guarantee the access rights of traditional subsistence and artisanal fishers to marine and inland fisheries resources, and provide local fisheries-dependent communities priority rights to the resources on which they depend for their livelihoods;
- Recognize the value of indigenous and local knowledge, culture and experience in resource management and facilitate the empowered participation of local communities in the use, management and protection of aquatic resources;
- Strongly support policies and mechanisms that promote an integrated, sustainable livelihoods approach to coastal and aquatic resources management by developing alternative livelihoods and adding value to certain resources, thereby relieving pressure on other scarce aquatic resources;
- Improve scientific research and environmental education for all aquatic ecosystems;
- Facilitate the engagement of local communities in the implementation of integrated coastal zone management procedures, with particular support for Developing States;
- Grant the communities that depend on fish resources for their livelihood both in the marine and inland sector common property rights over the resources.
- Provide support to artisanal and small-scale fish workers, taking into account the social, economic and environmental importance of this sector;
- Ensure priority rights of the artisanal and subsistence fishers to the coastal and inland areas where they live and

- the aquatic and inland resources to which they have customarily enjoyed access for their livelihoods;
- Adopt appropriate legal and policy measures to protect access and use rights of women fish workers to coastal and marine resources;
- Seek a rational and equitable balance between social and economic objectives in the exploitation of the living aquatic resources accessible to traditional, artisanal and subsistence fishers by taking particular account of the needs of politically, socially and economically disadvantaged fishers; and
- Evolve, on a priority basis, necessary mechanisms for the release and repatriation of small-scale fisher people arrested for transborder movement into waters of neighboring states, taking into account the fact that such movement is often the result of poor fisheries management and depletion of local coastal resources”.

The fact is that most of these recommendations just as easily fit for traditional resource users on land such as traditional hunters, pit sawyers, charcoal makers, pastoralists, honey collectors, etc. Wilkinson (2002) mentions, discussed in some detail in Chapter 9, that governments reluctantly devolve authority of the management of natural resources to lower authorities. In the Philippines, a model has evolved in which the local authorities (*barangays*) have been encouraged to manage their own coastal resources. This model is spreading to Indonesia. Wilkinson (2002) recommends that communities:

- Be given the necessary information in culturally and linguistically appropriate ways;
- Be involved in all stages of resource management, especially in initial assessment and mapping to determine the extent and status of resources;
- Trained in coral reef and fishery monitoring;
- Helped with alternative livelihoods to avoid the destructive exploitation of reefs;
- Target community and religious leaders to head up the process;
- Be prepared to take on responsibilities of devolution and governments to devolve; and
- Use successful projects as demonstration to neighboring communities to join in.

Wilkinson (2004) recommends that

“co-management of resources by local communities should be encouraged to prevent collapse in fish stocks and improve enforcement; and management needs to be adaptable to local conditions, traditional management techniques, and fishing cultures to ensure a more effective self-enforcement of regulations”.

The fact is, regardless of where one goes in the world, without local support, no resource is manageable. This is especially true in developing countries, where most coral reefs are found, and where the majority of the people have their livelihoods directly tied to living off the resources. Integrating them into the decision-making and active management/monitoring of the coral reefs and their resources has a much better chance of succeeding than trying to establish prohibitions (no take MPAs), unless there is a buy-in from the community and in the long-term they agree that it is in their interest.

Below are a few initiatives beginning off the East Coast of Africa in Tanzania. Similar attempts are being made in South Africa such as along the coast of Natal, South Africa (Funston, *pers. comm.*) (Chapter 9, Section 9.6.3.8, CBNRM, subsistence fishery, Lake St Lucia, KwaZulu Natal, South Africa).

8.14.1 Community Coastal Zone Management, Tanzania

“The Tanga Coastal Zone Conservation and Development Program, in partnership with the Wildlife Division of the Ministry of Natural Resources and Tourism (MNRT) and with IUCN support, have established collaborative management agreements for coastal fisheries and mangrove forests. The two major objectives of this program are to improve the capacity of government to undertake integrated coastal zone management, and to assist communities in using coastal resources in sustainable ways, including the restoration of degraded environments

(Makoloweka, Gorman, Horrill, Kalombo, Kawau, Lugazo, Shurcliff, Uronu & van Ingen. 1996; 1997 both *In:* Barrow, Gichohi & Enfield, 2000). Priority environmental issues have been identified and include declining fish catches, destructive fishing techniques, mangrove cutting and coastal erosion. The project's approach has been one of initial 'listening and testing', followed by training and learning through doing (Makoloweka, *et al.*, 1996 *In:* Barrow, *et al.*, 2000). This is summarized in the approach of 'listening, piloting, demonstrating and then mainstreaming' (Van Ingen & Makoloweka, 1998 *In:* Barrow, *et al.*, 2000). Village initiatives have included new bylaws, mangrove and tree planting, reef zoning and closures, and form the basis for collaborative fishery and mangrove management agreements" (Barrow, *et al.*, 2000).

Village environmental committees developed six collaborative management plans along the entire coastline. The health of these reefs has improved based on the following factors (Wilkinson, 2002):

- Fish populations are larger;
- Catch rates are up; and
- Destructive fishing practices (e.g., dynamite fishing and beach seining) have declined due to collaborative enforcement between villagers, district officers and the navy.

No take areas have been established to serve as a core to feed fish into the surrounding areas. Village monitoring teams, in collaboration with district officers and the IUCN, survey and then open/close areas depending on coral cover and the abundance of target fish and invertebrates.

"The passing of the Marine Parks and Reserves Act in 1994 allowed marine parks to be gazetted in a manner that actively involved and integrated customary users into the park management and enabled sustainable use of resources. Using this act as a basis, a general management plan for Mafia Island Marine Park was developed to attempt to integrate the needs of the rural people with

those of conservation (Andrews 1996; 1997 *In: Barrow, et al.*, 2000). However, despite strong policy support for full community participation, the responsible institutions are still reluctant to change (Andrews 1996; 1997 *In: Barrow, et al.*, 2000) (Barrow, *et al.*, 2000).

The Misali Island Conservation Area of Pemba, Tanzania is the basis for an innovative approach to community fishery and coastal resource management (Cooke & Hamid, 1998 *In: Barrow, et al.*, 2000). The fisher community is highly diverse, comprising 1,640 fisherpersons from 29 coastal wards or Shehias (Cooke & Hamid, 1998 *In: Barrow, et al.*, 2000). The basic approach has been to consult the community fully and to involve them directly in formulating objectives and work plans, and to evolve a sustainable mechanism for community participation in the long-term management of Misali. This led to the development of a committee system as the principal means of decision-making by the community, and legislation with an outlined management plan to legitimize this system and working resolutions. Legislation developed by the project aims to ensure that the community has an effective collaborative role in management through the granting of powers for management to a management committee, which is dominated by community representatives. In order for this to work more efficiently it is proposed to create the Misali Island Conservation Association as an NGO which can solicit for funds and project activities. The community response to date appears to have been very good, with the lesson that full community participation must be the basis for any successful local protected area in such places (Cooke & Hamid, 1998 *In: Barrow, et al.*, 2000) (Barrow, *et al.*, 2000)”.

8.15 KEY ACTIONS TO MITIGATE THREATS TO CORAL REEFS

The following table (Table 8.14) summarizes the relative importance (H = high, M = medium, L = low) of the objectives under each goal outlined in the Strategy and National Action Plan to address key threats to international coral reef ecosystems by region.

Table 8.14: Key actions to coral reef protection

ACTION	Wider Caribbean	East Asia	Pacific	East Africa / Indian Ocean	Middle East
Map shallow reefs (<30 m)	M	L	L	L	M
Map deep reefs (>30 m)	L	L	L	L	L
Conduct rapid assessments and inventories	L	L	M	M	L

Rankings were provided by official representatives to the International Working Group of the U.S. Coral Reef Task Force (CRTF). The U.S. Coral Reef Task Force was established by President William (Bill) Jefferson Clinton in June 1998 through Executive Order #13089 to lead U.S. efforts, both domestically and internationally, to protect, restore and sustainably use coral reef ecosystems. Chaired by the Secretary of the Interior and the Secretary of Commerce, the Task Force is composed of the heads of 11 federal agencies and the governors of seven states, territories or commonwealths with responsibilities for coral reefs. A higher ranking suggests that conducting the objective is considered more important to addressing current threats to coral reefs in the region. Lower rankings suggest that although implementing the objective may make significant contributions, it is currently less important to addressing the major threats to coral reefs in the

region. The actual importance of each objective in addressing threats to reefs will vary within and between regions depending on conditions, location and other factors (Evans, 2002).

It should be noted that today land-based pollution issues are noted as high priorities across the globe, regardless of the geographic region. In order to monitor the impacts of land-based pollution, the Caribbean Water and Wastewater Association (CWWA) has made water quality monitoring a priority, especially for the critical nutrient parameters (Sealy, 2002). While Table 8.14 places nutrient and sediment pollution as high priorities globally, water quality monitoring is given a medium to low priority, which appears contradictory since nutrients and sediment water quality along with percentage live/dead coral reef and epiphytic algal cover should be monitored at permanent long-term sampling sites on key reefs, especially in developed watersheds. Wilkinson (2004) goes into some detail on various monitoring efforts globally. Goreau (2005) believes that too much emphasis is put on monitoring when we know many of the reefs are degraded, as opposed to developing action oriented programs to work with local people in dealing with sewage, re-growing their reef and reef fish management.

8.15.1 Training and Capacity Building

“Most coral reef countries lack trained personnel for coral reef management, awareness raising, enforcement and monitoring. Moreover they lack the necessary resources to implement effective management. Thus, there is a need to:

- Assist in the training of environmental resource managers and ensuring that they are provided with in-country employment;
- Assist countries in the development of alternative livelihoods to combat poverty and the need to over-exploit coral reef resources (see Chapter 9, Section 9.7.8.3, Need for non-rural livelihood alternatives through industrialization);
- Assist developing countries to design, implement and manage networks of MPAs to conserve their resources;

- Consolidate the training provided by UN agencies and MEAs (Multilateral Environmental Agreements) to ensure that they are targeted on resources, issues and problems relevant to conserving national resources;
- Provide adequate and long-term financial and logistic resources for developing countries to undertake environmental planning for the longer-term, rather than the 3-5 year funding cycle of projects (see Chapter 11, Section 11.7.2, Foreign Aid Conditionalities Good Business for Donor Country not Recipient/Host Country);
- Assist in the recognition of appropriate traditional knowledge and methods of environmental management and help governments harmonize these with state and national laws; and
- Develop the ‘capacity to build capacity’ and use train-the-trainers and peer-to-peer exchanges as low cost (Wilkinson, 2004)”.

Many of these same issues are discussed in some detail in Chapter 9. As much emphasis needs to be placed on training and educating individuals from the communities (Chapter 9, Section 9.7.5, Lack of Technical and Management Skills) as government bureaucrats. Youth trained at the university level can return and work with their communities to both sustainably manage and valorize their resources

8.15.2 An Innovative Attempt to Bring Back Corals – 3rd Generation Artificial Reefs

The principal author undertook his master’s thesis on artificial reefs from tires. In the past old vehicles, train cars, cement rubble from building demolition, felled trees, etc. were used in coastal zones and reservoirs, especially on bottoms of sand and mud, as a means of artificially enhancing fish habitat. This was mainly for sport fishing. In recent years, Goreau (2004d) has developed a technology, which is trying to speed up coral recovery once the source of coral death (pollution, global warming, etc.) is eliminated and/or minimized. Goreau believes his method

grows corals four times faster than normal, survives high temperatures, sediments and algae overgrowth 16 to 50 times better than surrounding corals, creating superior habitat with incredible numbers of fishes, as well as turning eroding beaches into growing ones. In the Maldives in 1998, only 1-5% of corals survived heatstroke caused by global warming, but in the same habitats, 50-80% of the corals on Biorock™ structures survived. One of his Indonesia projects covers about 0.5 km, and has 1,000s of corals of around 200 species. The Biorock™ Process or mineral accretion is a revolutionary technology developed by Prof. Wolf H. Hilbertz and coral ecologist, Dr. Thomas J. Goreau, of the Global Coral Reef Alliance, which grows structures and marine ecosystems in seawater (Global Coral Reef Alliance, 2004).

“Artificial reef construction by means of mineral accretion, also known as ‘third generation’ artificial reef systems (first reported in Asian Geographic in 2001), is a novel technology which uses electricity to ‘grow’ limestone rock on artificial reef frames and increase growth rates of corals and other reef organisms. Two electrodes supplied with low-voltage direct current are submerged in seawater. Electrolytic reactions at the cathode cause minerals naturally present in seawater to build up” (Sea Science, 2002).

“Biorock technology applies a safe low-voltage electrical current through seawater, causing dissolved minerals to precipitate onto cathodic surfaces growing into white limestone/brucite structures similar to those that make up coral reefs and nourish tropical white sand beaches. Biorock methods speed up coral growth even where excessive temperatures, pollution, sedimentation and other stress-inducing factors have damaged reefs and other marine habitats” (Global Coral Reef Alliance, 2004).

At the same time, a wide range of organisms on or near the growing substrate are affected by electrochemically-changed conditions, shifting their growth rates. Stray or loose living corals are carefully collected from nearby destroyed reefs

and transplanted²¹⁴ onto the structures. They are attached with wires or wedged between steel bars. These coral bits are quickly cemented into place by the growing minerals forming over the structure's surface; the reefs are electronically charged to grow (Coral Reef Alliance website, Sea Science).

Biorock technology provides a cost-effective and sustainable method to accelerate coral growth and increase coral survival particularly in areas where environmental stress has affected existing reefs.

“The Biorock™ process grows limestone rock that is predominantly made of the mineral aragonite, the same mineral that makes up the skeletons of coral and most coral reef rock and sand. Young corals prefer to settle on clean limestone surfaces, and settle on it when they will not settle on exotic materials such as steel, concrete made with hydraulic cement, plastics, or rubber tires. Juvenile corals settle on Biorock™ materials at high density. Corals growing on Biorock™ structures are healthier and have much more energy for resisting environmental stress, and so are able to survive stresses that kill neighboring corals. As environmental stresses from global climate change and increasing pollution increase, corals on mineral accretion structures are increasingly likely to be the only survivors....This makes them ‘Coral Arks’ for preserving species from extinction from global change, and for maintaining the ecosystem services” (Goreau, 2003b).

“Corals normally have to spend a large part of their metabolic energy reserves creating high pH conditions internally in order to grow their skeleton, but the Biorock® process provides these essential conditions for free, leaving the coral with much more

²¹⁴ Not using any of the above technology, Tamelander and Obura (2002 *In: Wilkinson, 2002*) found that natural coral recruits and surviving coral colonies fared better than transplants in terms of growth rates, survivorship as well as cumulative growth. This was likely due to the stress of cutting transplants making them vulnerable to predation and disease especially at the damaged edges of the transplanted fragments. Where background coral growth was poor, transplant growth was likely to be poor. This implies that 1) creating an artificial substrate to allow natural recruitment using the above technology might work better than transplants and 2) unless the source of degradation is removed (e.g., sewage, agricultural runoff) then transplants using the above technology or just placed in the area will likely not grow well.

energy for tissue growth, reproduction, and resisting environmental stress. Corals growing with the Biorock® process grow several times faster than normal. The specific growth enhancement depends on the species and the specific operating conditions. Typically these are such that the coral is growing 2-5 times faster than normal, but much higher rates, up to 10 times faster, have been reached. Staghorn corals, which normally grow 15 cm per year under good conditions, grew 10 cm in just 10 weeks. Finger corals in a highly polluted environment grew about 5 times faster than normal. Large head corals appear to grow around 2-5 times faster as well, but there are big differences between species” (Goreau, 2003b).

Of course, this can never hope to replace the beauty of a live vibrant coral reef – at least not in your lifetime or mine.

8.16 CONCLUSION

Coral reefs are threatened globally, primarily from land-based pollution and since 1998 from global warming.

Africa has many lessons to learn from the mistakes of more evolved regions of the world such as America, Australia, the Caribbean, Central America and the Indian Ocean islands where inappropriate tourism development has destroyed coral reefs that serve as a basis for all that attracts tourists in the first place: clear blue water, white sand beaches, seafood, SCUBA diving and sport fishing.

The east coast of Africa, where the majority of the continent’s colonial corals are found, is fortunate that most of its coastline, other than a few large cities, is relatively undeveloped, which is where the Caribbean and Florida Keys were back in the 1960s and early 1970s. There are many lessons to be learned from the Caribbean about how not to develop the coastlines and about appropriate technologies such as the treatment of brown and gray and water.

If you see degraded coral reef, unless there is dynamiting as off southern Tanzania and maybe northern Mozambique, turn around, walk up to the beach, spread your arms like a profit giving a sermon and gaze into the watershed where 90% or more of the problem can be identified. Improperly treated sewage, as a key component of land-based pollution, is believed to be one of the prime causes resulting in nutrient pollution, since often this sewage is literally dumped on top of coral reefs by coastal tourism facilities. Thus tourism, among other land-based activities, is destroying the very attractions that bring tourists to the world's coastal zones in the first place. Other causes of reef degradation include sedimentation from land-based poor soil conservation or improperly located agricultural activities and associated agro-chemicals, over-grazing and industrial pollution. While issues such as global warming that in 1998 resulted in a global mass die-off of coral reef and depletion of the ozone layer must be dealt with on an international level by such groups as the UN, WTO and UNEP, these issues must not replace taking on-the-ground actions to deal with land-based pollution.

Key coral reefs that are in need of protection can be identified along the East African Coast, where damage is already occurring , (e.g., Mafia Island, Bazaruto Complex off Mozambique). Developers and governments need to be sensitized that it costs just as much to invest in sustainable development (e.g., proper location of lodges behind primary dunes, appropriate sewage technology, etc.) as to do it wrong, resulting in a more secure investment in the long-term. One can work with hoteliers, dive operators, fishermen, small-scale farmers, woodcutters and pastoralists to better manage their resources and to decrease sedimentation, pollution and destructive practices that adversely impact the natural resources of the nearshore waters. These are things one can put one's finger on and do something about, much more so than regarding global warming and the ozone

layer. Moreover, if we wait for these “big picture” issues to be dealt with, by the time they are addressed, land-based pollution risks to have wiped out the reefs.

With the movement towards decentralization (*gestion des terroirs*), consideration should be given to empowering fisher communities along the coasts to manage segments of the coastline including the corals, grass beds and mangroves and their associated fisheries within the boundaries of these designated areas. This should include helping them to develop sustainable harvest programs for their fish. Youth from fishing communities need to be sent for tertiary training in fisheries/environmental and protected area management, as apprentices in running sport fishing and dive operations and eventually to run and operate their own tourism businesses as on Ambergris Cay in Belize (e.g., the sons of fishermen becoming dive operators, glass-bottom boat operators and sportfishing guides). Ultimately, fisher communities must be part of the solution integrated into as opposed to alienated from modern conservation concepts as they are applied to Sub-Saharan Africa’s coastal zones, especially East and Southern Africa where the majority of the coral reefs are found. To be successful in the long run, conservation of Africa’s coastal zones must first and foremost meet the needs of local residents and last and least those of international NGOs and tourists.

Meanwhile, and on the return from their studies, youth selected from these fisher communities can work with them to establish permanent reef monitoring, water quality and fishery statistics programs to assure sustainable development that conserves these unique, biologically diverse and economically important coral, mangrove and grass bed ecosystems.

If outside developers wish to come in and engage in joint venture with such communities, part of the cost of development should be following certain prescribed environmental guidelines that deal with issues such as sewage and gray

water disposal, the position of buildings and lights with regard to beaches and turtle nesting sites, rules to prevent minimal impacts on corals from SCUBA divers, boat anchors and rules regarding spear/sport fisherman. Monitoring and education of youth from local communities must be considered a recurring cost of doing business and should be part of the investment portfolio. Ultimately, one must ask if humankind wishes to see healthy colorful coral reef (Figures 8.1 & 8.6) or dead and dying reef (Figures 8.2, 8.3 & 8.5) that is becoming so common across the globe. The choice is ours!

Chapter 9

9.0 COMMUNITY-BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS - THE WAY FORWARD FOR SUB-SAHARAN AFRICA?

“In old Africa, there were decision makers in the villages. Their decisions seemed to favor conservation. Now we try and influence national planners in the capital to achieve nature conservation. But the village decision maker still decides whether or not he will kill the last leopard in his stretch of the country. Something is out of balance. Can the balance be restored” (Dasman, 1976 *In:* Edwards, 1994)?

...“political, cultural and economic considerations may be more important than biological ones in cropping wildlife” (game cropping) (Blankenship, Parker & Qvortrup, 1990).

Marks (1984) best sums up the dilemma of modern conservation in Sub-Saharan Africa, the conflict between Western imposed conservation and African conservation, in his infamous book The Imperial Lion, described by one of the founders of CBNRM, Marshall Murphree (*pers. comm.*), in the early 1990s as “my bible”:

“...the management of wild animals abroad must be defined within the social as well as biological context...the metaphorical lion which Northern European wildlife managers have fostered, in the name of ecology (today in the name of biodiversity), of wildlife survival, and as a legacy for humanity, on the seemingly benign African landscape is an imperial lion...of assumed privilege, of unwarranted access to another society’s life-sustaining resources, and of interference in their liberty. Its genesis and sustenance comes from outside the continent on which it roams. The imperial lion is a frightful beast for it comes unexpectedly to destroy, and

its presence disturbs the community until people find the means by which to neutralize and dismiss it. Its natural enemy is the lion of African culture to which it has become increasingly vulnerable. This spiritual lion is rooted in traditions and realities...of identity, of self-respect, of autonomy. It is this lion's presence which wildlife managers must learn to cultivate and to enhance by increasing their understanding of the social consequences of human actions. Their failure to do so will help destroy what managers and conservationists value most on the African continent" (Marks, 1984).

"...much is now known about community based natural resources management and how it failed its promise to deliver both conservation and development..." (Dzingirai, 2004) in a report put out by IUCN-ROSA (Regional Office for Southern Africa).

"As Africans achieve greater political maturity, however, Bonner thought, they will no longer 'allow themselves to be dominated by Europe and the United States. 'They threw off colonialism once,' and Bonner now predicted that 'one day they will throw off eco-colonialism in the management of their wildlife and other aspects of the environment' " (Bonner, 1993 *In:* Nelson, 2003a).

About " 'one thing there can be no doubt, however: the old orthodoxy of conservation purely as a state-enforced protection, which evolved in the colonial era and was continued by the elites who took control of independent Africa in the 1950s and 1960s, is no longer presented as a viable option by any serious actors' " (Hulme & Murphree, 1999 *In:* Fabricius, Koch & Magome, 2001).

Living off donor handouts and often educated in the West and/or in Western conservation philosophy, the techno-bureaucratic elites tend to still represent developed world interests and norms, where wilderness is a valuable and affordable antidote to urban living (Child, B, 2004a). The voiceless rural masses are still seen as more of a nuisance to these elites and their private sector partners and the ongoing patronage system that dominates to the benefit of everyone but the rural poor, who must live from nature and co-habit with wildlife.

The first eight chapters of this book discuss traditional resource management and demonstrate how European colonialism poured over Africa, like water from a collapsed dam, in attempting to obliterate systems of traditional management and governance, while replacing them with European approaches and technologies, often inappropriately used to manage resources. Rather than mixing together into one, this clash of cultures has been like two liquids of distinct density, oil and water, refusing to blend together.

This chapter discusses a concept made popular in the mid-to late 1970s beginning with Zimbabwe's development of the Communal Areas' Management Program for Indigenous Resources (CAMPFIRE). Since administration and control through repression by centralized governments was not saving wildlife, the idea arose of sharing wealth from the sustainable use of resources with rural people. The idea was that community conservation would fulfill human needs, with conservation being the means to achieving and maintaining this end (Jones & Murphree, 2004 *In: Child, B., 2004a*). This chapter attempts to provide an overview of the practical experiences and evolution in thinking over what has become known as Community-Based Natural Resource Management (CBNRM). IUCN/SASUSG²¹⁵ (1997) provides a very clear definition of the concept of "sustainable use" on which CBNRM is based:

²¹⁵ International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU) and Southern Africa Sustainable Use Specialist Group (SASUSG) of IUCN/The World Conservation Union Regional Office for Southern Africa

USE – is the derivation of the benefit from a wild natural resource in one or more of the following respects:

- Economic or financial;
- Social or cultural;
- Political; and
- Ecological.

SUSTAINABLE USE – is use that allows for the continued derivation of benefit

As such, there are no valid distinctions between

- Consumptive and non-consumptive use;
- Commercial and subsistence use; and
- Conservation and sustainable use.

However, in much of Sub-Saharan Africa, “sustainable use” equates to consumptive use of natural resources based on sound biological, social and physical data especially through the harvest of wildlife, but also timber, fish, agricultural products and livestock. In essence, “sustainable use” is equated with “conservation”.

Eco-tourism is normally defined as non-consumptive use since the tourist is not taking the life of a living creature, that is, there is no harvesting. Thus, eco-tourism practices “protection” or “no use” for example in parks, where there is minimum active management which allows nature, through “natural regulation”, to take its course. However, there are major costs inherent in eco-tourism, such as pollution of the environment from sewage and solid waste due to high volumes/turnover required to generate income, and as described in Chapter 8, there are often adverse cultural impacts from wealthy tourists buying what they want from the poor living around the natural areas (e.g., prostitution, rare or endangered wild products such as seashells, black coral, ivory, python skins, etc. harvested without concern for sustainability) . So, with eco-tourism there can be consumption, although this does not take place in the classical sense.

A synthesis of information gathered from the principal author's personal experiences while an advisor to several African governments, the U.S. Agency for International Development (USAID), managing the Africa Office of Safari Club International (SCI)²¹⁶, as well as manager of the African Initiative of the Department of Nature Conservation, Tshwane University of Technology,²¹⁷ along with information provided by innovators in this field and the literature, attempts to provide insight as to where CBNRM is today and maybe also where it is going. Some attempts are made to recommend a future direction for the CBNRM process.

This chapter analyzes CBNRM as currently practiced in some of the more important programs and begins looking at how it might evolve both internally and externally. It also discusses how CBNRM must fit into a bigger plan for the economic development of the subcontinent if conservation is to be effective. The limited impacts of CBNRM on household livelihoods are discussed in more detail in Section 9.7.6.4, CBNRM will not create a "middleclass" in Africa.

9.1 THE CULTURAL DIVIDE

Community-Based Natural Resources Management (CBNRM) programs reward rural Africans for the loss of access to their resources in parks and protected areas (e.g., hunting blocks) by providing them with material compensation for foregoing traditional ties to wildlife and other resources.

However, a major cultural divide still exists between Western approaches to conservation and traditional African approaches. This divide must somehow be

²¹⁶ Safari Club International, 4800 West Gates Pass Road, Tucson, Arizona 85745-9490 USA, Main Phone: (520) 620-1220, Fax: (520) 622-1205, <http://www.safariclub.org> & conservation/education/humanitarian assistance arm - Safari Club International Foundation, <http://www.safariclubfoundation.org>.

²¹⁷ P/Bag X680 Pretoria 0001, South Africa.

overcome or preferably integrated, taking the best from both worlds, to enable wildlife in Sub-Saharan Africa to survive the onslaught of humanity in the 21st century.

The manner in which Westerners from urban industrialized societies and many urbanized Africans view wildlife has little direct economic significance. Westerners place emphasis on the intrinsic or recreational values derived from these resources. Their definitions of conservation are couched in abstract terms such as “biodiversity” and “ecosystem maintenance” and their objectives become those of the maintenance of species and habitats for aesthetic, recreational or scientific purposes (Barrow & Murphree, 1998; Murphree, 1998a). Vande weghe (2004) argues that “biodiversity” is a new word, which evolved out of biological diversity in the 1980s and has come of age since the Rio Summit. It designates “the variability of living organisms from all origins, at gene and species level as much as at ecosystem level”. He considers it an “incommensurable concept – vague and ambiguous...It is not measured but described” and thus can mean anything and everything, having become everyday jargon used in global eco-politics. Rural Africans are more concerned with sustainable productivity of wildlife as a source of revenue and protein (Barrow & Murphree, 1998; Murphree, 1998a) along with cultural, religious and spiritual ties to wildlife.

As discussed in Chapter 3, the West’s main approach to conservation in Sub-Saharan Africa is the separation of humans and wildlife through the creation of “Sherwood Forests” (parks, game reserves and hunting blocks) across the continent with the aim of declaring 10% or more of each country as parks and protected areas as established by the IUCN (see Chapter 11, Section 11.10.6 Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers). These areas have been set aside for exclusive use by rich, mostly white, tourists from America and Europe. Africans

are excluded, as they cannot afford entrance fees, hunting licenses or vehicles (most parks require a vehicle to enter). The idea of separating humans and nature is an alien concept to most Africans.

Ultimately, this approach cuts rural Africans off from legally accessing what they perceive as “their resources” and from their social, cultural, spiritual and ancestral ties to them, as discussed in Chapters 2 and 3 of this book. Mindful of the fact that co-evolution with wildlife makes “conservation” as practiced a concept difficult for them to comprehend, in addition, this alien concept disenfranchises rural Africans and turns them against conservation. Traditional hunters become poachers, as they are required to access wildlife and other resources clandestinely. Traditional controls that might have existed to manage the resources are lost through centralization of resource management and alienation of the rural populace. “Common Property Resources” become “Open Access Resources” and are mined for short-term gains. This has been a recipe for failure. Values and beliefs between Westerners and Africans are like night and day. Westerners assume material rewards will change attitudes, forgetting the mystical, ancestral and cultural ties of Africans to their resources.

Many Westerners, for example, will find it hard to believe in transmogrification²¹⁸ of a human into a wild animal, while for many Africans, this is an easily understood fact. One culture looks at this as folklore and superstition, while the other culture sees this as a normal process linking them to their spirit world (e.g., *Hommes Leopard, Mhondoro* the ancestral lion) (see Chapter 2, Section 2.1.8, Taboos as an Aid in Wildlife Management and Section 2.3.1, Land).

²¹⁸ Suggests a grotesque or preposterous metamorphosis

The real question we need to ask ourselves is not whether lycanthropy²¹⁹ or other traditional African beliefs are true or not true, any more than questioning the transformation of bread and wine into the flesh and blood of Jesus Christ by Catholics. Whether lycanthropy is physical or psychological, the question arises as to how we can overcome these cultural divides to the benefit of Africa, its people and its natural systems. Martin and O'Meara (1995) state

“it is vital for Western agents involved in negotiating the political and economic future of African nations to recognize that the culturally specific character of African social organization is not an artefact of the past, but a vital cultural resource that has the power to consolidate community identity and mobilize community action in modern Africa”.

Murphree (1995) states, with regard to the *Tchuma Tchato* CBNRM project in Mozambique, that identification and support of traditional authorities and traditional religious leaders (spirit mediums -*swikiro*) secured the project concept at an early stage and can be the key to the long-term success or failure of a CBNRM program in Africa.

Here lies the major challenge for 21st century conservation in Sub-Saharan Africa: to integrate traditional controls and beliefs, as described in Chapter 2, with Western ideas on conservation and management, something at which we have failed miserably over the last 20 years of the 20th century and here at the beginning of the 21st century. Can indigenous values (e.g., totems and taboos), controls (e.g., territory, seasonal mobility and closed seasons) and institutions (e.g., chiefs, elders and hunting guilds) now be re-empowered to help drive sustainable economic and political development? Do these institutions possess the capacity for the social, political and economic exigencies (requirements)

²¹⁹ The assumption of the form and characteristics of a wolf – in the case of Africa often of a lion, leopard or hyena as discussed in Chapter 2 - held to be possible through witchcraft and/or linked to the ancestors.

demanded by early 21st century developments (Davidson, 1992 *In: Zack-Williams*, 2002) or can they be revived?

In many cases, traditional authorities have been contaminated by clientelism and the kleptocracy typical of the post-colonial mode of governance. In many cases, the “traditional leaders” and “chiefs” of today are politically appointed to carry out the mandates of central government, robbing the rural areas of accountable leaders (Baker, 2002). The search for a functional democracy should neither ape Western institutions, nor modernize feudalism (Davidson, 1992 *In: Zack-Williams*, 2002). This applies from the level of the state down to local resource management systems. The up-and-coming generation of young Africans educated in nature conservation must determine how to integrate the old and the new by taking the best from each in an attempt to find “African solutions to an African problem”, as opposed to relying entirely on Western governance and management systems, imposed on Africans, which to date have failed. Hinz (2003) presents one of the first analyses in the possibility of using traditional authorities, now officially recognized within Namibian law, to help in managing wildlife as a result of decentralization policies. He recognizes that at the local level, there are relationships between traditional authorities, local authorities (local government), conservancy committees and regional councils that must be negotiated and clarified as to their role in sustainably managing Namibia’s natural resources.

This integration is critical, since even if they were to operate fully, it is not evident that the traditional ways of extensively managing natural resources alone are any longer viable due to the human population explosion of the 20th century and the resulting pressures for material gain placed on the resource base at the beginning of the 21st century. At the same time, Western intensive management systems, even when adapted to the African continent over 100s of years as in Southern Africa, are often rejected by traditionally living rural Africans. Given

the incredible pressure today on habitat and resources from traditional nomadism and declining fallow periods, and the smaller and smaller areas harboring wildlife (e.g., in the Limpopo Province South Africa, the average game ranch is less than 1,000 ha), intensive management of these small game ranches/areas becomes critical to prevent resource and habitat degradation while assuring that Africa can sustain itself both nutritionally and economically.

Ultimately, unless they are accommodated, international values and goals will be subverted by local responses ranging from defiance (e.g., poaching, illegal grazing, fishing and honey collection) to covert non-compliance (Murphree, 1998a) (e.g., revenge killing - attempts to eliminate wildlife so that it has no value to hunting and other forms of eco-terrorism such as burning down park headquarters and killing of park staff).

9.2 THE CRITICAL LINK, CBNRM AND ADAPTIVE MANAGEMENT IN AFRICA

9.2.1 Precautionary Principle; Studying Wildlife to Extinction

Western scientists and researchers, especially in East Africa have tended to dominate conservation using the “precautionary principle”. The protectionist approach of the precautionary principle (founded in Western urban industrialized settings where humans have lost their dependency on surviving directly off the environment) purports that wildlife and its complex life cycle must be fully understood before it can be used and that this requires time and extensive research.

What this means, in essence, is passive management of the species, allowing “natural regulation” to dominate as the management approach, which assumes

that nature will take care of itself. The best examples of this can be found in Uganda and Kenya, where American and British-based animal rights groups, and Western researchers with no management skills have taken an anti-sustainable use policy.

It needs to be made clear that research and management require two completely different sets of skills and mind sets. A researcher is trained to test hypotheses, to study and continue finding more information that will allow him/her to better understand how a system or organism functions. This is often a life-long pursuit. On the other hand, managers, relying on available information, are trained to take action (e.g., cull, burn, introduce more game, etc.) in order to manage an area while identifying data gaps. As the data gaps are filled, a more complete picture develops and better decisions can be made as to the manipulation of a natural system to achieve management objectives (e.g., trophies, meat, higher predator population and greater biodiversity). Researchers are action-oriented people. Ideally, a protected area-manager will have access to researchers to help fill data gaps. For instance in the KwaZulu-Natal Nature Conservation Service (KNNS), reserve managers call in researchers as needed, but not the other way around.

Unfortunately, in places like Kenya and Uganda, primarily American and British researchers run the show with donor backing, and either because of philosophical differences and/or fear of the unknown, there is no management. As a result, in the average rural area, there is little or no added value from wildlife (Kenya allows game cropping for a limited national market and there is bird shooting/Uganda has a pilot trophy hunting program - see Chapter 11, Section 11.11.2.8, Pilot hunting scheme), so rural people are making a wise decision by eliminating the game and converting the habitat to something that can earn them a livelihood (e.g., livestock pasture) or alternatively selling off these assets (e.g., to

be converted into small farms and commercial wheat schemes) as they opt out of “valueless wildlife” as a land use and head to the cities.

In modern Africa, where nature is increasingly surrounded by human fences so that wildlife cannot disperse as its numbers increase, such an approach is a recipe for disaster with risks of over-population, habitat destruction, increased human/wildlife conflicts, a loss in biodiversity and possible population crashes. In Africa, by the time wildlife has been studied extensively enough to please proponents of the “precautionary principle”, rural communities, in trying to survive, may have opted for other land uses, resulting in the elimination of the very wildlife-critical habitat one was hoping to conserve.

9.2.2 “Adaptive Management”

Child, G. (2004b *In:* Child, B., 2004a) explains the management phases that Southern Africa’s parks and protected areas evolved through:

- 1. Phase 1, “military mentality”** (e.g., anti-poaching, burning).
- 2. Phase 2, “stock-raiser’s mentality”** military management combined with a build up of herbivore numbers (e.g., elimination of predators such as in the Kruger Park in South Africa, where 19,440 mammals, birds and predators were killed from 1903-1927 or the Hwange Park, Zimbabwe, where wild dogs were shot as late as 1960) and viewing opportunities for tourists (e.g., boreholes to concentrate wildlife, resulting in over-grazing, bush encroachment and the loss of perennial grasses needed for soil stability in savannas and the loss of obligate grazers such as roan and sable in favor of mixed feeders such as kudu and impala and bulk feeders such as elephant, hippo and buffalo – see Chapter 6, Section 6.2, BOREHOLES AND WILDLIFE).

3. Phase 3, “era of ecologists”, 1950s-1970s, development of range management principles, abolition of predator control and more control over the placement of boreholes and the attempt to eliminate wildfires, while using controlled burning to fulfill management objectives and understanding that these areas are not self-regulating ecological units and are best controlled using what became known as “adaptive management”, emerging in the 1960s. The Transvaal Provincial Administration Nature Conservation²²⁰ authority of South Africa did not adopt adaptive management principles until the 1980s (Reilly, *pers. comm.*).

“Experience in the region has shown that the process of adaptive management with its negative feedback loop is essential for the sustainability of CWM²²¹. The dynamic nature of rural communities and the resource base requires an approach that allows for fine tuning as the program develops” (IUCN/SASUSG, 1997).

The adaptive management approach relies on a crude evaluation of wildlife resources based on available data on a specific species in order to make conservative estimates of sustainable off-take. This off-take is monitored while data gaps are identified and filled to help make better management decisions on how to best utilize wildlife as an economic and rural development tool for rural Africa:

- Preliminary but conservative quotas based on field surveys;
- Adjusting quotas annually based on an appropriate and cost effective wildlife monitoring program [e.g., trophy quality, hunting success, hunting effort, herd structure and size, recruitment, aerial

²²⁰ This was the name of the pre-1994 body that since 1995 has been divided into Limpopo, Gauteng, Mpumalanga and Northwest Provinces, each with their own conservation administration.

²²¹ Community Wildlife Management – basically CBNRM

surveys (if available), along with decision support, rainfall, pasture quality]; and

- Based on a theoretical off-take of only 2-5% of annual game population for trophies and another 10-25% for meat.

Adaptive management is the basic tenet of Southern Africa's approach to sustainable use. It is a pre-requisite for CBNRM to begin, since poverty, despair, alienation and disenfranchisement will not wait for Western scientists to study wildlife and its habitat to the detriment of the people and their resources.

Duffy (2000) believes that sustainable use is possibly the only means of ensuring the survival of wildlife in Sub-Saharan Africa, by halting the conversion of key wildlife habitat to other land uses. She also states that preservationist policies have proven politically untenable, resulting in wildlife being removed from Sub-Saharan Africa because local people have no reason to conserve wildlife that has no value beyond the aesthetic. It is believed that these two divisions are a bit simplistic. Certainly, as has been demonstrated, rural communities have strong cultural and religious ties to wildlife that makes it in their interest to conserve it. However, as we shall see, people living in poverty and at a subsistence level do not have the luxury to plan for the long-term and land hunger throughout the continent makes it difficult for rural people to justify conserving wildlife today, unless the wildlife and its habitat are part of their short-term survival portfolio. As we shall see, sustainable use linked to CBNRM has an important role to play, but alone is likely to fail unless it becomes part of a bigger picture plan for developing the continent!

9.3 COMMUNITY-BASED NATURAL RESOURCES MANAGEMENT (CBNRM) PROGRAMS – PART OF THE WAY FORWARD

CBNRM is not the answer, but one of a number of conservation strategies that may have merit outside parks. More and more, it may also include parks and the use of resources within parks as is discussed here and in Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers. For CBNRM to work, it must continue to progress towards people living on the land having ownership over the land, wildlife and other resources, and the right to sustainably use and directly benefit from these resources. Currently, CBNRM is too top-down and patronizing (Murphree, 2001 *In:* Baldus, Hahn, Kaggi, Kaihula, Murphree, Mahundi, Roettcher, Siege & Zacharia, 2001; Murombedzi, 2003 *In:* Adams & Mulligan, 2003). The idea of involving communities in conservation has evolved over the last 25 years and is continuing to do so (Roe, Mayers, Grieg-Gran, Kothari, Fabricius & Hughes, 2000). Initiatives include:

- **The 1980 IUCN “World Conservation Strategy”,** which stressed the importance of linking protected area management with the economic activities of local communities (Roe, *et al.*, 2000) and which led to the development of national conservation strategies.
- **The 1982 World Congress on National Parks in Bali,** which called for increased support for communities through education programs, revenue-sharing schemes, participation in the management of reserves and the creation of appropriate development schemes near protected areas (Roe, *et al.*, 2000).

- **The Wildlife and Human Needs Program** launched in 1985 by the World Wildlife Fund (WWF), which attempted to combine conservation and development (Roe, et al., 2000).
- **The 1986 World Bank “Policy on Wildlands”**, which recognized that the protection of natural areas must be integrated into regional economic planning (Roe, et al., 2000).
- **The Rio Declaration of 1992 Leading to the Convention on Biological Diversity (CBD)**, which arose out of the 1992 UN Conference on Environment and Development in Rio de Janeiro and emphasized three equally important objectives: conservation, sustainable use of biodiversity resources and the fair and equitable sharing of benefits with local indigenous people, thus placing community involvement in wildlife conservation and management firmly on the international agenda (Roe, et al., 2000). Article 22 of the Rio Declaration on Environment and Development (UN, 1992a) supports indigenous management and knowledge systems as critical to sustainable development, as well as cultural ties to natural resources (Koch, 2004 In: Fabricius, Koch, Magome & Turner, 2004). The CBD (UN, 1992b) puts people at center stage in promoting fair and equitable benefit sharing and sustainable use (Fabricius, et al., 2001). Also arising out of Rio were the Statement of Principles for the Sustainable Management of Forests (UN, 1992c) and Agenda 21 (UN, 1992d), a comprehensive global plan of action addressing humans and their impacts on the environment (UN, 2003). Agenda 21 provides an overview of key issues that must be addressed in the 21st century to link conservation and development including (UN, 1992d):
 - Social and economic dimensions including poverty, health, human settlement and linking environment and development in decision-making;

- Conservation and management of natural resources for development including integrated planning and management of land resources, deforestation, desertification, fragile alpine ecosystems, sustainable agriculture and rural development, biodiversity, biotechnology, management of oceans and coastal zones and their resources, protection and management of freshwater, management of toxic substances, hazardous wastes and radioactive substances and solid waste and sewage management,
- Strengthening the role of major groups in conservation and development including women, children and youth, indigenous people, NGOs, local authorities, workers and trade unions, business and industry, scientific/technological community and farmers; and
- The majority of funding for Agenda 21 in developing countries is to come from the 0.7% GNI/GNP²²² of the developed/industrialized countries in the form of foreign aid also known as Overseas Development Assistance (ODA) (UN, 2003). As is seen in Chapter 11, Section 11.7.1, Foreign Aid as Portion of Donor Country GNP, only six of 22 developed countries met this goal in 2003. Funding for CBD, work plans and operational and research projects is provided by the Global Environment Facility (GEF) managed jointly by the World Bank, UNDP and UNEP and paid for by industrialized countries (Fairhead & Leach, 2003). GEF also supports Agenda 21 (UN, 1992d). However, “ ‘the central feature of the GEF is that it exists to meet the incremental costs of global environmental benefits. It would not therefore be appropriate for it to be the funding mechanism for other

²²² Gross National Income (GNI) = Gross National Product (GNP). See Footnote 48, Chapter 5, Section 5.2, ECONOMICS OF AGRICULTURE IN AFRICA.

conventions that are designed to achieve national or regional benefits' " (Dalyell, 1993 *In: Colchester, 1994*).

"Many of these projects of 'global benefit' have very worrying implications for indigenous peoples. Since GEF funded projects or project components are, by definition, not in the national interest, the projects have the effect of marginalizing indigenous peoples' concerns" (Colchester, 1994).

- **The "Earth Summit" or 2002 World Summit On Sustainable Development (WSSD) in Johannesburg, South Africa,**

"views of civil society were given prominence at the Summit in recognition of the key role of civil society in implementing the outcomes and in promoting partnership initiatives. Over 8,000 civil society participants attended the Summit, reinforced by parallel events which included major groups, such as, NGOs, women, indigenous people, youth, farmers, trade unions, business leaders, the scientific and technological community and local authorities as well as Chief Justices from various countries" (WSSD, 2002).

The full implementation of Agenda 21, the Program for Further Implementation of Agenda 21 and the Commitments to the Rio principles were strongly reaffirmed at the WSSD (UN, 2003).

- **The Durban Accord** of the 2003 World Parks Congress, which concluded the following:

"We see protected areas as vital means to achieve this synergy efficiently and cost-effectively. We see protected areas as providers of benefits beyond boundaries—beyond their boundaries on a map, beyond the boundaries of nation-states, across societies, genders and generations...We voice concern that many costs of protected areas are borne locally—particularly by poor communities—while benefits accrue globally and remain underappreciated...We voice concern that many protected area

practitioners lack access to technology, knowledge, lessons learned and best practice models for effective and adaptive management. We voice concern that the capacity of our younger generations to participate in the new protected area agenda is insufficient...We urge commitment to ensuring that people who benefit from or are impacted by protected areas have the opportunity to participate in relevant decision-making on a fair and equitable basis in full respect of their human and social rights. We urge commitment to protected area management that strives to reduce, and in no way exacerbates, poverty. We urge commitment to protected area management that shares benefits with indigenous peoples and local communities. We urge commitment to innovation in protected area management including adaptive, collaborative and co-management strategies. We urge commitment to recognize, strengthen, protect and support community conservation areas...We urge commitment to innovative and diversified income generation strategies, thereby securing predictable financial returns for payment to the stewards of ecosystems goods and services" (WPC, 2003).

Additional agreements affecting people - natural resource relationships in Sub-Saharan Africa include (Fabricius, *et al*, 2004):

- The “**Protocol on Tourism Wildlife and Law Enforcement**” of the Southern African Development Community (SADC), which calls for economic and social incentives from conservation and the sustainable use of wildlife;
- The “**Protocol on Shared Watercourses**” of SADC, which respects customary laws;
- The “**World Heritage Convention**” on the protection of the world cultural and natural heritage, which integrates cultural and biological conservation;
- The “**Convention to Combat Desertification**”, which has the participation of communities as a core principle;
- The “**Ramsar Convention**” or “**The Convention on Wetlands of International Importance Especially Waterfowl Habitat**”, which

advocates wise use of wetlands as economic, cultural and recreational values;

- **The “International Covenant on Civil Rights and Political Rights”,** Human Rights Committee, General Comment 23, Article 27, 1994, which stresses the rights of indigenous people to land resources including hunting and fishing and the right to live in reserves protected by law;
- **The “International Labor Organization (ILO) Convention”,** which recognizes the rights to land of indigenous people, with Article 11 stating that Aboriginal title is embedded in memory and does not depend on an act of state (see Chapter 11, Section 11.10.1, Foreign Aid for “Conservation”? for further discussion);
- **The “Dana Declaration on Mobile People and Conservation”,** which recognizes the contribution that nomadic people can make to conservation;
- **The “Principles and Guidelines on Indigenous Traditional Peoples and Protected Areas”,** IUCN World Conservation Union Resolution 1.53, 1996 amended in 1998, which calls for the development of policies in protected areas that safeguard indigenous people with respect to customary practices and traditional land tenure systems; and
- **The “Man and the Biosphere Program”** guidelines of the United Nations Educational, Scientific and Cultural Organization (UNESCO), which call for the linking of communal lands to conservation areas through buffer zones.

The Convention on International Trade in Endangered Species (CITES) of Wild Fauna and Flora is mentioned, but as is seen in Chapter 10, CITES tends to ignore economic incentives and the integration of indigenous people into the management of Africa’s flora and fauna in favor of trade sanctions, which create black markets, making management impossible.

Thus, there is a growing realization and acknowledgement that indigenous people living within or peripheral to most parks and protected areas must play a strong role in conservation and see development evolve from benefits accrued through conservation. Except CITES, the above conventions and accords begin recognizing that indigenous people must be involved in determining how protected areas are managed and what they are managed for. This may fly in the face of what Westerners want from conservation. In fact, it is rural people, not governments, who will ultimately determine the future of protected areas.

However, achieving results on the ground, as the case studies in this chapter and Chapter 11 show, is another story. The interventions by Western donors, their NGOs and African governments violate many of these agreements and in the 21st century are still destroying the lives of indigenous people, compressing them into areas that will not support them and creating exclusion zones that in the past provided them with a vast array of resources necessary for their survival. To date, most of these CBNRM programs have been failures,

“generally paternalistic, lacking in expertise, and one-sided—driven largely by the agendas of the conservationists, with little indigenous input”,

most conservation NGOs being unsuited to deal with social and economic issues (Chapin, 2004).

9.3.1 Defining Community

“Most attempts to link biodiversity conservation to development of local people are flawed for two reasons. The first is the dogged belief by most policy-makers and practitioners that the ‘community’ exists and that its is the best vehicle for implementing biodiversity programs. The notion that a ‘community’ is a group of homogenous people, all with common interests and beliefs, is

false...The second flaw is a strong belief that the ancient rural past – prior to modernization – was compatible with nature and that it can be easily recreated. However, there can be no return to a harmonious state of nature. Hence, the pieces of the puzzles rarely fit because the issues surrounding biodiversity conservation continually present themselves as moving targets in a fierce battlefield of competing and conflicting interests” (Magome & Murombedzi, 2003 *In:* Adams & Mulligan, 2003).

Roe, *et al.* (2000) in the review and summary of a number of regional reports on CBNRM by the International Institute for Environment and Development (IIED) under the rubric “Evaluating Eden”, provide the following insights to “community”. In general, as a starting point for the Evaluating Eden analyses, the following definition is provided

“Community: a grouping of people associated in spatial, social, cultural or economic terms which occupy, have access to, or have a legitimate interest in, a particular local geographic area”.

The Southern Africa analysis defined community as,

“a figment of the imagination of project managers and donors seeking quick fixes. The common belief amongst donors and project managers is that it saves time to group people together, because of the simplicity of working with fewer groups”...”. A community in the Southern African context is defined as a group of people with a self-defined collective identity. Thus there exist ‘communities of interest’ (people who have defined themselves as belonging together because of sharing the same interests, or pursuing the same livelihood strategies)”.

Thus, within a given village or among a number of villages there may be a number of “livelihood clusters” or “communities of interests” (e.g., traditional hunters, fishermen and honey collectors). The assumption that a village or group of villages is/are composed of one homogenous community all with common interests is one of the major reasons for conflicts in CBNRM programs.

The West and Central Africa report points out

“that many communities defy definitions based on spatial or social criteria, since many people are often transient. They suggest that ‘community’ is better understood as a number of common interest groups between whom management of wildlife resources must be negotiated”.

The South East Asia analysis defined community as,

“a socially and geographically defined group of people living near, or dependent on, species/ecosystems which are sought to be conserved”.

However, they go on to say that

“communities can also be fragmented by social, political, or economic differences, some of which can deny the opportunity to real resource users to participate in decision-making”.

The Central American analysis defines community as,

“people who share a space - village, town, farm, forest - and who share some social and cultural characteristics”.

IIED (1994 *In: Roe, et al., 2000*) tends to agree with the Southern African conclusions that

“what may appear to be a community on the ground (i.e. in spatial, social and cultural terms) may in fact be deeply divided in relation to individuals’, institutions’ and households’ interests in, and control over, different kinds of wildlife” or resources.

Roe, *et al.* (2000) conclude that for the purpose of CBNRM:

- Communities are fluid and constantly redefine themselves;
- Different livelihood groups (e.g., hunters, fishermen, sawyers and charcoal makers) or communities of interest exist within the same geographically defined community; and
- It appears to be more useful to use resource management groupings or 'clusters' rather than geographical entities to define communities.

Junge (2004) found that rural communities in Sub-Saharan Africa were not homogenous, varying within and between communities based on age, gender, social group, poverty, wealth, education, livelihood strategies and capabilities. While a community may be defined: 1) spatially, within a defined geographic area, 2) socially, with a common history and cultural heritage often based on kinship, and 3) economically, with groupings sharing interests and control over particular resources, Junge (2004) also raises issues over the fluidity and dynamics of continually changing community membership as a result of forced relocation, migration, rural/urban labor resource flows and changing agricultural practices such that clearly bound social and residential units may not be present.

As individuals become involved in CBNRM at an on-the-ground level, great care must be given as to what a community is in order to avoid, as is seen in some case studies below, the chief or group of community elites absconding with the benefits to the exclusion of the majority. Thus CBNRM decision-making bodies must be representative of various interest groups or stakeholders (e.g., clans, villages, women, youth, loggers, charcoal makers, fishermen, hunters, honey collectors, traditional medicine herbalists who collect their remedies from the bush and thatch grass collectors among others) linked to a defined geographical area to assure that everyone's needs are integrated into the program, the

management of the natural area in need of protection, and to assure that as many people as possible, both collectively and at the household level, receive benefits.

As is seen below, in most CBNRM programs, the integration of household livelihood and livelihood needs is often ignored, while the greater community, (the village or villages surrounding the natural areas) is expected to be happy with common property benefits such as schools, clinics and boreholes. This policy has and is failing where such approaches continue. For instance, Long (2004) states that in Namibia's CBNRM process, and this reflects CBNRM in general, while governments and NGOs are proponents of creating various broad-based bodies such as conservancies, trusts, section 21 companies, associations, etc., most resource use and management decisions take place at a household and inter-household level. For instance, despite attempts at community game meat distribution in Namibia's conservancies that tends to be irregular and often a once a year affair, 25% continue to depend on the illegal harvest (poaching) of both large and small mammals as important to their livelihoods. Thus, two different levels of resource management and decision-making exist within CBNRM areas: household/individual resource users/specialists and "conservancy". This has the effect of distancing primary resource users from resource management decisions of the "conservancy", resulting in a need to integrate this lower level of decision-making into planning and decision-making at the higher level.

9.3.2 Defining Wildlife in the Context of CBNRM

Roe, *et al.* (2000) conclude after looking at all regional analyses of "Evaluating Eden" that "wildlife" is best defined as including "animal and plant resources and their habitats". This makes sense given the diverse array of resource users as noted above that must be integrated into management of natural areas, if these areas are to be of value to local residents at all levels, helping to assure the

sustainable use of the natural systems in question and their survival from degradation (e.g., over-exploitation or mining for short-term gains) or conversion to other land uses that people feel can provide them with improved livelihoods. Unfortunately, most current CBNRM programs, as discussed below, are too narrowly focused on generating revenue from wildlife through trophy hunting.

9.3.3 Defining CBNRM

CBNRM is said to be about sustainable use of natural resources outside the park estate. What about within the park estate? Critics say that CBNRM is based on the assumption that “community” is defined as small-scale human groupings socially bound by a common cultural identity, living within defined spatial boundaries, interacting on a personal rather than bureaucratic basis, and having an economic interest in common pool interests of the area. Such conditions rarely exist in that local settlements are often culturally heterogeneous, economically stratified, boundaries are porous and social cohesiveness is fragile. Thus, CBNRM cannot be based on a “definition” for community. CBNRM is directed towards the collective management, use and controls on use of “Common Property Resources”, with benefit derivation and distribution from such use. It is directed at local levels, below large bureaucratic units created by governments at national or district levels (e.g., below District councils). CBNRM is about local collaborative regimes of natural resource management with defined membership and jurisdiction. It is not about private individual ownership (e.g., commercial game ranches), unless they choose to collaborate communally as in a conservancy (Murphree, 2001 *In:* Baldus, *et al.*, 2001).

Barrow and Murphree (1998, *In:* Roe, *et al.*, 2000) identify three categories of community conservation that have emerged in Africa (see Table 9.6):

- “Protected area outreach”: seeks to enhance the biological integrity of parks by working to educate and benefit local communities and enhance the role of a protected area in local planning (e.g., Integrated Conservation and Development projects – ICDPs). Jones and Murphree (2004 *In: Child, B.*, 2004a) describe this as the “fences and friends” approach;
- “Collaborative management”: seeks to create agreements between local communities or groups of resource users and conservation authorities for negotiated access to natural resources, which are usually under some form of statutory authority. Jones and Murphree (2004 *In: Child, B.*, 2004a) describe this as the “no-fences and mutual benefit” approach; and
- “Community-Based Natural Resource Management (CBNRM)”: the sustainable management of natural resources through returning control over or responsible authority for these resources to the community. This is basically devolution if carried out in full.

“CBNRM builds on the price-proprietorship-subsidiarity paradigm. If the resource is valuable (price), if this value is captured by landholders (proprietorship) and if the principle is followed that no management action, decision or benefit is arrogated to a higher level when it is better and more appropriately conducted at a lower level (subsidiarity), there is a high likelihood of successful resource conservation and management” (Child, in preparation *In: Jones & Murphree, 2004 In: Child, B.*, 2004a).

As is seen in this chapter, CBNRM has gone through a number of stages, with the ultimate goal of “devolution” or full ownership. Devolution or full ownership implies management rights, decision-making rights for the use of the resource(s) and the right to benefit from a given natural area by the community stakeholders/interest groups. It should imply tenure over land and associated natural resources. As mentioned throughout in Fabricius, *et al.* (2004), the evolution of CBNRM is not linear in nature. There is not any real blue print to success. While guidelines are provided in this chapter, each CBNRM program

must be dealt with down at the level of the producer communities for a given area that is to be placed under management. Different cultures, individual personalities and national policies, among others, will impact on how CBNRM is structured and evolves. Some of the newer CBNRM programs have bypassed earlier stages, learning from the older programs.

Most CBNRM programs are quite far from achieving the goal of full devolution, being at some level of co-management as defined by Hasler (1999 *In: Roe, et al.*, 2000), collaborative negotiated management as defined by Dubois, 1997; Agarwal, 1997; Zeba, 1998²²³ (all *In: Roe, et al.*, 2000) or decentralization (Murphree 2001, *In: Baldus, et al.*, 2001) most often in collaboration with government, the private sector and conservation/development NGOs. The reasons behind the failure to achieve full devolution are discussed (see Section 9.7.2, Reluctance to Devolve Control and Ownership of Resources to Landholders).

Steenkamp (2000) is not convinced that co-management is necessarily advantageous to local people or to biodiversity conservation. Livelihood concerns are not automatically incorporated into their design, a major weakness, nor do they always provide the best guarantee for efficient conservation development and biodiversity management, especially if local livelihoods/access to resources have not been adequately negotiated. Formal frameworks of CBNRM and co-management regimes tend to clash with the cultural, economic and political realities on the ground. As is seen, in many cases this so-called co-management “Conservation with the People” is a way for governments and the private sector to take control over and expropriate the majority of the wealth from the resources that should be accruing to local communities and traditional resource users. Thus, devolution becomes aborted.

²²³ Referred to as “West and Central African Report”

Unfortunately, until these middlemen are out of the picture and until rural communities break these shackles of bondage, it is the former who will reap the majority of benefits, be it the government and private sector (safari and tour operators) or indirectly from living off donor handouts (NGOs) with minimal benefits returning/reaching the people on the ground. In fact, as is demonstrated in this chapter and Chapter 11 on foreign aid, very often at both the household/family level and “community level”, rural stakeholders are worse off under CBNRM than if they had been left alone to their own ways and traditions.

Many of the constraints to the orderly evolution of CBNRM must be seen as remnants of colonialism that have been imposed on rural communities over the last 40 years of independence by political elites in mostly non-representative governments. More recently, Western donors and their surrogate NGOs have taken the reins in imposing their wishes on rural communities. As is seen below, a key to helping rural stakeholders break this bondage will be to get a critical mass educated to the point that they know what they have with regard to its value, how to sustainably manage it and that they are able to effectively stand up for their rights. Then and only then can one hope for full devolution. As is seen, serious tertiary (university) education has not been one of the strong points of CBNRM. One must ask “why”? and it is believed that the “why”? is that it would weaken the stranglehold that governments, the private sector and NGOs have on the resources that should belong to rural communities and serve as their catalyst for development from their sustainable use.

9.4 ORIGINS OF CBNRM IN AFRICA

As noted in Chapter 2 of this book, prior to the start of the colonial era, resource management was largely carried out in the informal sector. These resource

management systems were sustainable in the sense that they had survived until the 19th century, prior to the advent of colonialism.

During the 20th century, revival of informal sustainable resource management systems was prevented by the centralization of management controlled by bureaucracies (see Chapters 3, 4, 5, 6 and 11). This disenfranchised local communities from their resources, through such practices as license controls, protection policies and enforcement through a coercive paramilitary culture (Peluso, 1993; Hitchcock, 2000a *In:* Marks, 2001). Parks, game reserves and hunting blocks were formed that excluded local people through “fortress conservation” or the “fence and fines” approach. This approach has failed (Junge, 2004).

Control of resource use, previously largely the domain of traditional leadership, was progressively alienated to government. By the 1970s, legal access by rural communities to wildlife had become virtually impossible throughout much of the subcontinent. However, by the 1970s and 1980s, the ability of governments to enforce sustainable use of resources began to be reduced due to constraints of capacity and resources. This led to the progressive withdrawal of government from the direct control of resource use, often delegating authority to third parties, or leaving a vacuum of authority resulting in conditions of “open access” to these resources. In either case, this situation is generally recognized as a sufficient condition for “unsustainable resource use” and for highly inequitable access to resources with monopolization by elites. Examples are the transfer of customary land to estates in Malawi (Chapter 5), the monopolization of vast tracts of natural areas by a few large safari operators, tourism companies (Bell, 1999) and logging companies or NGOs (Chapter 11 for the last two examples), as seen all over Sub-Saharan Africa.

The problems of access and sustainable management were exacerbated by the population explosion in the 20th century. By the 1970s, conservationists were becoming concerned that protected areas created at the end of the 19th through to the 20th century were becoming islands surrounded by a sea of poverty; vulnerable to encroachment and the poaching of wildlife (Marks, 2001). Conservationists were convinced that wildlife would disappear unless local communities became more integrated with and benefited from these areas (Marks, 2001). Hulme (1997) and Barrow and Murphree (1998) believe that CBNRM is widely accepted by the Washington Consensus market driven theories of the 20th century, where wildlife is a commodity and the role of government in market economies is diminished - becoming widely favored by Western donors and NGOs. As will be seen, policy-makers, academics and practitioners have come to question this neo-liberal approach (Fabricius, *et al.*, 2001), at least as it is currently practiced.

It also fits well with neo-populist ideas of returning “power to the people”, participation, decentralization and increasing the use of indigenous knowledge in decision-making, where cultural and spiritual values, in addition to market forces, are key determinants in how people relate to wildlife. Both schools believe that the role of the state is to create an enabling environment in which conservation and development can take place, but not to administer them (Hulme, 1997).

In Southern Africa, by the 1960s and 1970s, there was a growing appreciation that the loss of habitat and competition with domestic stock were the primary causes for the continued decline of wildlife outside parks and protected areas, resulting in various degrees of users’ rights being conferred onto commercial (white) farmers: Zimbabwe 1960 and 1975, Namibia in 1967 (Bond, Child, de la Harpe, Jones, Barnes & Anderson, 2004 *In:* Child, B. 2004a) and South Africa between 1967 (Mulder, *pers. comm.*)²²⁴ and 1968/9 (Lambrechts, *pers. comm.*),²²⁵ when game

²²⁴ Dr. Piet Mulder, retired Head of the Department of Agriculture, Conservation and Veterinary Services, Gauteng Province, South Africa, Tel: 27 (0) 12-567-2975, p fsmulder@mweb.co.za.

fenced farms received exemption permits that gave landowners year-round control over their wildlife as a commodity/economic resource.

At about the same time, pioneering work in game ranching was undertaken by American Fulbright scholars Thane Riney, Ray Dasmann and Archie Mossman in Zimbabwe, demonstrating its economic and ecological viability (Child, G., 2004 *In: Child, B., 2004a*). While initially, wildlife as a fugitive resource was seen as a low value source of protein with a limited market because of veterinary restrictions, new production systems evolved, converting grazing into services where economic output was less directly linked to ecological output/primary production by giving added value from a combination of trophy hunting, photo-tourism, meat production (Bond, *et al.*, 2004 *In: Child, B. 2004a*) and even live sales.

Livestock or wildlife used purely for meat production depends on a direct link between primary (grass/browse) and secondary production (meat), often requiring the rancher to over-stock his range for short-term economic gain resulting in habitat degradation from mining environmental capital. Even after five decades of subsidies, only 5% of the cattle enterprises in Zimbabwe were profitable, while wildlife proved to provide a better return on investment (Bond, *et al.*, 2004 *In: Child, B. 2004a*).

The legislation providing ownership of wildlife to commercial farmers, pioneering research and improved terms of trade for wildlife resulted in the development of an important wildlife-based economy in Southern Africa on private land (Bond, *et al.*, 2004 *In: Child, B., 2004a*).

²²⁵ Lampies Lambrechts, former Director of Conservation Services, Transvaal Chief Directorate of Nature Conservation, the Old Transvaal, South Africa, 27 (0) 82-556-6158, lampies@netactive.co.za.

Trophy hunting provided tremendous value from harvesting only about 2-5% of the annual population by species, while another 10-25% could be harvested for meat, the total percentage off-take corresponding more or less to the annual population growth rate. In Southern Africa, trophy hunting served as the “embryo of conservation” outside parks on white commercial ranches (SCI African Chapter, 1996), providing a low investment incentive to build up wildlife populations, generate income to build photo-tourism lodges and have adequate game as a source of meat/protein. Wildlife, once a fugitive resource, became a commodity that was bought and sold. Closure of hunting in Kenya in 1977, civil wars in Uganda (1972-1985) and Sudan (1983 to present) (Bond, *et al.*, 2004 *In:* Child, B. 2004a), and the temporary closure of hunting in Tanzania from 1973-84 (Bonner, 1993)/1973-1978 (Baldus & Cauldwell, 2004) helped orient overseas hunters to Southern Africa and aided in the development of this industry. The extensive conversion of semi-arid rangelands to wildlife production really took off in the late 1980s (Bond, *et al.*, 2004 *In:* Child, B. 2004a).

The successful devolution of authority to the private sector over wildlife that eventually spread to Namibia, South Africa, as well as Botswana, Zambia and to a lesser degree Mozambique opened the door for the next step, thereby taking the concept of devolution into communal areas. Namibia and Zimbabwe were at the forefront concerning the devolution of authority to landowners to manage the wildlife on their land, arguing that unless wildlife provided tangible benefits to private landholders it would disappear outside state parks and protected areas. From 1971, Zimbabwe and Botswana led the debate on what has become known as CBNRM, while Zambia independently came up with similar ideas (Child, G., 2004 *In:* Child, B., 2004a). Bell (1999) believes that CBNRM developed out of two main strands in the Southern African region.

9.4.1 The Conservation Strand

Government control of wildlife and other biological resources was not working, a trend that was exemplified by the wave of elephant and rhino poaching in the 1970s and early 1980s. Classical law enforcement was failing. It was recognized that the alienation of access by rural communities provided no incentive for community participation in law enforcement; in fact, it led to quite the opposite. This strand of CBNRM, then, developed as an attempt to recreate a set of economic and social incentives that would motivate rural communities living with wildlife to participate in preventing illegal off-take. In most cases, as is discussed below; the social incentives have been largely overlooked (Bell, 1999).

9.4.2 The Social Equity Strand

The primary motivation was to redress the problems of rural poverty and inequitable access to resources. A major stimulus to this agenda was provided by the collapse of legitimate earning power over much of Africa in the 1970s and 1980s, which strongly exaggerated the problem of rural poverty (Bell, 1999), linked to the oil crisis and impacts of structural adjustment policies (SAPs) on national economies (see Chapter 12).

Simultaneously, with the peak of the West's environmental movement in the 1970s and 1980s, there was a push to link conservation to development. The International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU), through the World Conservation Strategy (IUCN, 1980), promoted the concept of linking conservation and development through donor assistance. This concept was further refined and confirmed by the Convention on Biological Diversity (CBD) of 1993, with 175 signatory nations supporting the conceptual role of indigenous and local communities in conserving biodiversity and

maintaining their traditional knowledge and practices through “conservation” and its antecedent, “sustainable use” (Glowka, Burhenne-Guilmin & Synge, 1994 *In: Marks*, 2001), originating with the Gifford-Pinchot philosophy as described in Chapter 3. As is discussed in Chapter 11 (Section 11.10.6.2, “Conservation and development” a continuation of failed “integrated rural development” linked to “preservation”), while they may be good at one or the other, very few NGOs are good at both conservation and development as an integrated concept.

CBNRM and similar community-based wildlife management (CWM) programs aimed to (Fabricius, *et al.*, 2001):

- Implicate communities voluntarily into the development of long-term solutions linked to natural resources in the hope of co-opting resource users into sustainable management activities as opposed to subversive plundering of resources by rural communities. The latter was taking place because of resource and land tenure changes and was a way for a rural community to show dissatisfaction with prevailing conservation laws and legal access to resources;
- Introduce the “new system” of group resource ownership and territorial rights with their management under the custody and control of resident communities;
- Provide appropriate institutions under which resources can be legitimately managed and exploited by local people for their direct benefit in the form of income, employment and meat;
- Provide financial and technical assistance to communities joining the program to help them achieve their objectives;
- Promote development using wildlife in rural areas and thereby diversifying out of agricultural-based systems into tourism and natural resource use; and

- Promote conservation of wildlife outside protected areas, thereby promoting protection within protected areas through these buffer zones since law enforcement within protected areas was inadequate.

Western donors, especially America, backed a number of similar programs in East and Southern Africa:

- ADMADE - Zambia, “Administrative Management Design for Game Management Areas (ADMADE)” funded by the U.S. Agency for International Development (USAID) through the Wildlife Conservation Society (WCS) of the New York Zoological Society;²²⁶
- NRMP – Botswana, “Natural Resources Management Program”, also called Botswana Community Trust Program funded by USAID through a U.S. consulting firm, CHEMONICS;²²⁷
- LIFE – Namibia, “Living in a Finite Environment (LIFE)” run through WWF/USA²²⁸ and funded by USAID;
- SCP - Tanzania, “Selous Conservation Program (SCP)” funded by the German funding agency- GTZ;²²⁹
- LIRD – Zambia, “Luangwa Integrated Resource Development Project (LIRD)” funded by the Norwegian Agency for International Development (NORAD);²³⁰ and

- *Gestion des Terroirs* - Burkina Faso, World Bank,²³¹ recent program of the 21st century.

As is seen below, even the Communal Areas' Management Program for Indigenous Resources (CAMPFIRE), designed by Zimbabweans to address the inadequacy of centralized management over the illegal off-take of wildlife by alienated rural Africans, was eventually high-jacked by the U.S. Government.

Thus, CBNRM is not at all about how people interact with wildlife and other resources in their daily lives, but about projects and programs. Pushed and funded by Western donors, millions of dollars have been spent to integrate conservation and human welfare (Marks, 2001; Murombedzi, 2003 *In:* Adams & Mulligan, 2003) and there are lessons to be learned. The institutionalization of community conservation in Africa through policies, programs and projects is largely a product of initiatives by international conservation agencies endorsed by state governments, shaped by conservation professionals and their NGOs, and funded by international environmental grant sources (Barrow & Murphree, 1998). Thus, CBNRM has been mainly donor-driven and top-down, full of Western urban biases about what drives a person to believe in conservation. De la Harpe, Fernhead, Hughes, Davies, Spenceley, Barnes, Cooper and Child (2004 *In:* Child, B., 2004a) conclude that driving CBNRM and conservation in general through donor funding has a number of disadvantages and is not sustainable: 1) funding cycles are short as donor priorities change and donor fatigue sets in from not seeing the rapid results expected within traditional funding cycles of three to five years, 2) project cycles are often flawed, pumping too much money in at the beginning before it can be absorbed, 3) the wildlife agency or community is subject to the personal preferences and values of the donor “take my money and

²³¹ The World Bank, 1818 H Street, N.W., Washington, DC 20433 U.S.A., Tel: (202) 473-1000, Fax: (202) 477-6391, <http://www.worldbank.org/>

you dance to my music”, which with regards to wildlife may be anti-culling/game cropping, and even anti-utilization in general, especially trophy hunting, and 4) donors are cumbersome and bureaucratic, cannot make quick decisions and are rarely innovative. With many donor projects, most of the money is government to government, never reaches people on the ground where management takes place and is absorbed in salaries, per diems, air-conditioned land cruisers and overheads by NGOs and governments or recycled back to the country of origin through its consulting firms, experts and NGOs, stimulating the donor’s economy more than Africa’s (see Chapter 11, Section 11.7, FOREIGN AID IN GENERAL).

CBNRM appears in many guises, including Integrated Conservation and Development (ICD), Community-Based Conservation (CBC), Community-Based Natural Resource Management (CBNRM), Community Wildlife Management (CWM), Collaborative (or Co-) Management (CM) and Protected Area Outreach Projects (Barrow & Murphree, 1998). Donors brought along their own baggage including decentralization, gender, transparency, democratization (Marks, 2001) and often compliance with IMF/World Bank structural adjustment policies (SAPs) as a prerequisite for donor support.

Donors recognized that African states were unable to centrally manage natural resources and with the re-emergence of democratic aspirations, Western donors began pushing for the devolution of resource rights to peripheral communities living in and around the parks and protected areas (Wilson, 1997 *In:* Marks, 2001). Thus, the stimulus, staffing and concepts did not come from the rural communities, nor were the resources expended directly on these communities, which would have made these programs more community friendly (Metcalfe, 1996 *In:* Marks, 2001).

“The communities were expected to receive projects gratefully as passive recipients to participate in proscribed ‘communities, and to accept benefits in prescribed packages’ ” (Marks, 2001).

In most cases, governments went along for the ride, placing themselves, along with the private sector, as indispensable middlemen between the people and their resources. By the time money filtered through all the interest groups (national and local government, private sector, NGOs), whether its origin came directly from the resource base or indirectly from a donor, little or nothing reached the people.

Beinart (2002 *In: Dovers, Edgecombe & Guest, 2002*) argues that

“Concepts such as community management of natural resources might describe what was done by communities but they are now elaborate frameworks, developed by intellectuals and activists globally, absorbed and adapted by states, and invoked by local communities as part of their political strategy in a new internationally recognized language although in some cases, such as Zimbabwe’s CAMPFIRE program, communities have not necessarily favoured the state’s version of community management,...”

which can be said for most of the “top-down” CBNRM programs. In most cases, as is demonstrated below, the steps towards taking control, let alone ownership, over wildlife have been designed by governments, NGOs and donors to be so complex that they are beyond the capacity of most communities, meaning more “overlords” controlling their every step and keeping them from truly obtaining independent “ownership” of their wildlife and other resources. NGOs, tour and safari operators, national and local governments all get in the way with their own agendas, including their own economic agendas. What the donors call “partners” are actually middlemen/parasites between the community and its resources, sucking up most of the wealth derived from wildlife and other resources. Most

middlemen purport that they “believe” in the tenets of CBNRM and who would not if they were making a killing on the backs of and at the expense of the people who are the rightful owners of the resource: rural communities.

Thus, a big difference between the wildlife “revolution” on the private ranches of Southern Africa and “devolution” to date in communal areas is that the landowner on private ranches pretty much controlled, but most importantly was the direct beneficiary of the daily rates and trophy fees from hunting, unless he/she chose otherwise (sub-contract marketing to safari operator). In the communal areas where CBNRM is practiced, on the other hand, communities were imposed on, dictated to over what resources could be harvested and were required to take on all kinds of middlemen partners (e.g., central and local government, safari/tourism operators and NGOs) to the point that little value accrued to the local level. This is demonstrated in some detail below.

9.5 SUCCESS OF CBNRM BASED ON CONSUMPTION AND COMMODITY PRODUCTION

Success tends to be measured here in economic as opposed to cultural and social terms – how much money can be made from wildlife. CBNRM tends to be market driven (Table 9.1), with trophy hunting being the key source of revenue in Southern Africa, where CBNRM originated.

The experience on private game ranches shows that raising wildlife for hides and venison though eco-friendly provides financial yields no greater than raising livestock, until tourism, both photographic and hunting are brought into the picture. This results in added value on the international market (Child, 1995 *In:* Murphree, 2001 *In:* Baldus, *et al.*, 2001). Tourism (hunting and photographic) is the primary reason for the financial success of CBNRM in Namibia, Botswana, Zimbabwe and Zambia. Like it or not, the majority of the revenue from CBNRM

projects comes from hunting. The implication for household income is broken down in Section 9.7.6.4, CBNRM will not create a “middleclass” in Africa.

Table 9.1: CBNRM tends to be driven by market forces for wildlife

MARKETS FOR WILDLIFE					
	Meat, Hides Products	Sale of Live Animals	Sport Hunting	Eco-Tourism	Mass Tourism
Local	Subsistence Requirements	None	None	None	None
National	Biltong, Venison, Skins and Ivory	Strong Demand From Private Sector for Restocking	Strong Demand From National Sport hunters	Significant Interest in Wilderness Trails and Wild Safaris	Citizens Unlikely to Seek Mass Wildlife Tourism
Regional	Markets Limited by Veterinary Constraints	Strong Demand From Private Sector	Strong Demand From Regional Sport hunters	Growing Market Largely From South Africa	May Develop in Some State Protected Areas
Inter-National	Large Potential Market for Ivory, Rhino Horn, Elephant Hide, Ostrich Products, Crocodile Skins, etc. but Constrained by CITES Treaty. Meat Limited by Veterinary Constraints	Hugh Market For Birds, Reptiles, Fish and Amphibians in International Pet Trade.	Strong Demand From USA and Europe. Robust Market Less Vulnerable to Political Factors	Rapidly Growing Market but Vulnerable to Political Factors	Already Affecting State Protected Areas. Unlikely to Affect CBNRM. Also Vulnerable to Political Factors

9.5.1 CAMPFIRE, Zimbabwe

Income to CAMPFIRE (in theory representing rural communities) from 1989-1999 (11 year period) totaled as follows (Bond, 2001a) (Table 9.2):

Table 9.2 CAMPFIRE income (US\$), 1989-1999

Year	Sport Hunting	Tourism	Hides/Ivory	Other	Total
1989- 1999	14,089,789	367,808	937,717	460,814	15,856,128
Percent of Total	83	3	12	2	100

Note: Other includes: Live Animal Sales, Collection of Ostrich and Crocodile Eggs, etc.

Source: Bond (2001a), with permission, WWF.

Khumalo (2005) provides a more up-to-date statistic of US\$ 20,289,784 to CAMPFIRE between 1989 and 2001 over a 13 year period, of which US\$ 18,152,074 came from trophy hunting (Khumalo, 2005) or an annual income of US\$ 1.56 million. In 1998, gross turnover from hunting in Zimbabwe was estimated at US\$ 20.6 million (Bond, 2001a) to US\$ 22.3 million (TRAFFIC, 2001 *In:* Baldus & Cauldwell, 2004; Khumalo, 2005), and US\$ 18.6 million in 1999 (Bond, 2001a). This amounts to a 7 - 8.4% of the gross turnover for the community depending on the gross.

In 1999, income from sport hunting to CAMPFIRE dropped to 70%, primarily due to the sale of ivory allowed under the Convention on International Trade in Endangered Species (CITES). If 1999 statistics are thrown out, sport hunting made up 91.5% of the total revenue to CAMPFIRE (Bond, 2001a; (Khumalo, 2005), 90% being the figure often referred to as the contribution from hunting. In 1995, Zimbabwe set a CITES quota of 300 elephants, 150 to CAMPFIRE and 150 to national parks who have state-owned safari hunting areas. Trophy hunted

elephant/year brought in 60% of the revenue that accrued to CAMPFIRE (SCI African Chapter, 1996). Since the political turmoil and radical land reform beginning around 2000/1, there is no way this level of income can be maintained.

9.5.2 ADMADE, Zambia

Similarly, 90% of money from the Administrative Management Design for Game Management Areas (ADMADE) of Zambia comes from hunting (IUCN/SASUSG, 1997). In theory, the ADMADE revenue stream flow is as follows (SCI African Chapter, 1996):

License Fees and Game Animal Fees:

- 50% to government; and
- 50% to revolving fund for NPWS capital replacement of vehicles and other disposable supplies.

Concession Fees - 100% Retained by Revolving Fund

- 40% to management of GMA; salaries of scouts, fuel, vehicle maintenance, rations, camp renovation;
- 35% to community development;
- 10% to national park management; and
- 15% non-self sufficient GMAs.

Promulgated in 2002 and implemented in 2003 with the re-opening of hunting after a two-year hiatus (Hunting was closed for two and a half years, re-opening in mid-2003), distribution of income to both the Zambia Wildlife Authority (ZAWA) and the local community appears as follows (Simwanza, 2006a; Simwanza, *pers. comm.*):

- **Animal Fees²³²**

- 5% to chief (if there is more than one chiefdom in the hunting area this amount is shared among the chiefs);
- 10% to central government (this money is retained by ZAWA);
- 40% to ZAWA; and
- 45% to Community Resource Boards (CRBs).
 - 45% to wildlife management (e.g., supporting community game scouts);
 - 20% to administration; and
 - 35% to socio-economic development.

- **Concession Fees**

- 5% to the chief;
- 15% to the Community; and
- 80% to ZAWA.

The ZAWA Commercial Director, indicates a similar distribution, except that ZAWA keeps 35% of the trophy fees (animal fees) and 15% goes to treasury (Mashinga, 2006; Pavay, 2006). According to Simwanza (*pers. comm.*), ZAWA retains this income (15%) to date. No analyses exist to quantify and compare actual revenue reaching the community under the old and new systems.

Lewis and Alpert (1997), estimated that the trophy hunting in Zambia grossed US\$ 3.1 million of which 5% went to booking agents, 10-15% to professional hunters, and 30% or about US\$ 1.3 million/year to the revolving fund (government). Faddy (*pers. comm.* 1999 *In:* African Advisory Board, 2000a)

²³² Hunting licenses no longer exist (Simwanza, 2006b). “Booking slips” have replaced hunting licenses in which harvested trophy animals are recorded for eventual payment (Simwanza, *pers. comm.*). There are also export permits and veterinary permits, it being unclear if these go to ZAWA or other government departments, and how this money is distributed (Simwanza, 2006c). This needs further investigation.

estimates that out of a gross turnover of US\$ 12 million/year, US\$ 700,000 (5.8% of gross) went to the communities. ZAWA (1999) and Lindsey, Roulet and Romanach (2006) indicate a total accumulated revenue contributing to the national economy of US\$ 5 million. It is unclear if this is gross turnover (total revenue brought in by safari operators) or the income going to the Zambian government from safari operators, resident (from within GMA) and non-resident hunters (citizens usually from the city), that is eventually split between government and rural communities. Simwanza (2005a) explains that the annual budget of ZAWA is about US\$ 5 million and by this rationale suspects that this is what the industry is worth. If one looks at confidential EU data in Section 9.8.5.1, (ADMADE) for 2001 ZAWA data, this for the most part agrees with Simwanza (2005a) as far as a gross government budget for ZAWA with about US\$ 3.1 million/year of the government budget coming from the safari industry. Likewise in 2005, out of a gross income to ZAWA of Kwacha 44,124,000,000 (\approx US\$ 10 million) the amount of 13,771,000,000 (\approx US\$ 3.1 million) came from hunting license and concession fees (Hamilton, Tembo, Sinyenga, Bandyopadhyay, Pope, Guillon, Muwele, Simasiku & Pavay, 2007). If based on Section 9.7.6.5, (Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders), about 26% of the gross goes to government, then the gross turnover value of safari hunting in Zambia would be about US\$ 13 million, very close to Faddy's (*pers. comm.*) estimate.

Based on an analysis of data from DeGeorges (1992a), it can be determined that under the old ADMADE Revolving Fund system, between 3.7 and 4.4% of the gross turnover went to the communities, but of this only between 1.7 and 2.0% went directly for community development, the rest going to local management (e.g., paying salaries of community game guards, etc.) respectively for Grade A²³³

²³³ Gross for Average Grade A Hunting Block [(US\$ 800/Day x 252 days = 201,600) + (18 Clients x US\$ 4,000/Client = 72,000 Trophy Fees + (US\$ 1,000/week Concession Fees x 36 weeks = US\$ 36,000) = US\$ 309,600 under old ADMADE Revolving Fund System.

versus Grade B²³⁴ hunting blocks (see Section 9.6.1.1, Zambia).²³⁵ Thus, based on the gross turnover of US\$ 12 million given by Faddy, this would amount to US\$ 204,000 – 240,000/year for community development in the late 1990s for about 22 GMAs (at that time) or US\$ 9,272-10,909/year/hunting block (GMA). Faddy (*pers. comm.* In: African Advisory Board, 2000) estimates that US\$ 700,000/year went to rural communities. However, if only 35% of this goes for true community development, the actual amount going to the community would be on the order of US\$ 245,000, coming to similar figures from two different directions.

9.5.3 Cullman Hurt Community Wildlife Project, Tanzania

It is estimated that hunting in Tanzania grosses from US\$ 27-39 million/year depending on the data employed, an increase from a gross turnover of US\$ 4.6 million in 1988 and US\$ 13.9 million in 1992 (Baldus & Cauldwell, 2004). Of this, the Wildlife Division makes from US\$ 10 million/year (Baldus & Cauldwell, 2004) to US\$ 12 million/year (Kibonde, *pers. comm.*): 60% from trophy fees, 10% from the annual block fee/concession, 20% from the conservation fee, 7% from the hunting permit fee and 3% from the trophy handling fee (Baldus & Cauldwell, 2004). Income per unit area for all hunting areas of Tanzania is US\$

Percent of Gross to Communities from Average Grade A Block (35% + 40% of concession fees) = US\$ 13,500/309,600 = 4.4% under old ADMADE Revolving Fund System.

Percent of Gross for Community Development from Average Grade A Block (35% of concession fees) = US\$ 6,300/309,600 = 2.0% under old ADMADE Revolving Fund System. Note: US\$ 13,500 and US\$ 6,300 actual average figures (Mwima, 1991 In: DeGeorges, 1992a).

²³⁴Gross for Average Grade B Hunting Block: [(US\$ 700/Day x 168 days = 117,600) + (US\$ 12 Clients x US\$ 4,000/Client in Trophy Fees = US\$ 48,000) + US\$ 500/Week Concession Fee x 24 Weeks = US\$ 12,000)] = US\$ 177,600 under old ADMADE Revolving Fund System.

Percent of Gross to Communities From Average Grade B Block (35% + 40% of concession fees) = US\$ 6,602/US\$ 177,600 = 3.7% under old ADMADE Revolving Fund System.

Percent of Gross for Community Development from Average Grade B Block (35% of concession fees) = US\$ 3,081/US\$ 177,600 = 1.7% under old ADMADE Revolving Fund System. Note: US\$ 6,602 and US\$ 3,081 actual average figures (Mwima, 1991 In: DeGeorges, 1992a).

²³⁵ Note: Actual concession fees to government/community paid by overseas hunters = US\$ 150/week classic 2 week safari and \$US 70/week mini 7-day safari. The difference kept by safari operator. Implies more weeks than used in average Grade A/B block to achieve actual community figures in Mwima (1991 In: DeGeorges, 1992a) meaning percentages could be even lower.

40/km² and in the Selous Game Reserve (SGR) US\$ 70/km² (Baldus & Cauldwell, 2004).

The Cullman Hurt Community Wildlife Project exists in the hunting blocks of Robin Hurt Safaris and was started by Mr. Hurt to make up for a void in government policy in sharing benefits with local communities as a means for them to become partners in conservation. All of the money for community development in the Cullman Hurt Community Wildlife Project, amounting to US\$ 650,000 between 1991 and 2000, is the result of a 20% surcharge on all trophy fees. Another US\$ 250,000/year is generated from an annual art auction used to fund anti-poaching and reward community game scouts for bringing in poachers and their hunting implements (Clarke, 2001). While the 20% surcharge is an excellent idea and should be sustainable as long as hunting continues, Clarke (2001) was concerned about the sustainability of the anti-poaching program, which relied on one man, Robin Hurt, and his contacts with a few “rich and famous” donors. Robin Hurt (*pers. comm.*) continually struggles to raise money. He believes that until wildlife belongs to Africa’s rural communities and until these communities receive all of the trophy fees (at a minimum) so that they can employ their own anti-poaching teams, the conservation of wildlife will suffer. Mr. Hurt believes that what he is doing is not sustainable and may not be replicable by other safari operators who do not have wealthy clients. In correspondence from Sally Capper (2003), she explains, “I am sad to say that I am leaving Cullman Hurt, due to lack of finances. We need to look at new ways to keep things going without a fulltime project director”. Joe Cullman, the driving force behind the art auctions, has just passed away (Jackson, *pers. comm.*), increasing the concerns raised above.

Even with the new policy (instituted in 1993), the “25% retention fund” from hunting go to local government (district council) and Hurt (*pers. comm.*) believes

that local communities will never see this money. Zacharia and Kaihula (2001 *In:* Baldus, *et al.*, 2001) and Junge (2004) came to similar conclusions. The so-called “25% retention fund” consists of 25% of 75% of the game/trophy fees, hunting block fees and professional hunter fees that go to the treasury, except in the Selous with a retention scheme where it is even less (Kibonde, 2004) (see Section 9.5.7, Selous Conservation Program (SCP), Tanzania):

Where there is no retention scheme the following fees are charged

1. Game fees, block fees and professional hunters’ fees:

- 25% Tanzania Wildlife Protection Fund (Fund used for budgetary operations by the Wildlife Division in addition to money from the Treasury and donors, World Bank, 2005); and
- 75% Treasury:
 - a. 40% retained by treasury;
 - b. 35% Wildlife Division; and
 - c. 25% district councils = “25% retention fund”

2. Permit fees, conservation fees, observer fees:

- 100% Tanzania Wildlife Protection Fund.

3. Trophy handling fees:

- 100% Tanzania Wildlife Protection Fund.

The fact that most of the “25% retention fund” do not reach the village, but are used at district headquarters level, fosters distrust among the rural populations. Communities feel that they are being cheated and that the benefits of wildlife utilization are reserved only for the elite government bureaucrats and for

foreigners (Nshala, 1999; Barrow, Gichohi, & Infield, 2000). The possibility of overcoming this with the creation of wildlife management authorities (WMAs) will be discussed. However, the foreign donor driven Local Government Reform Program (LGRP) raises concern over a serious lack of national ownership and how far government is willing to devolve authority and control over natural resources and other issues. GTZ, DFID, Frankfurt Zoological Society, USAID, NORAD, SIDA and other donors are supporting 80% of the total funding of CBNRM programs in Tanzania, which also puts into question the long-term sustainability of such programs. However risky, such reforms are necessary to find a solution to a “failed Tanzanian centralized state” (Junge, 2004).

9.5.4 *Tchuma Tchato*, Mozambique

Tchuma Tchato means “our wealth” (Fabricius, *et al.*, 2001). Just about all of the community benefits in Mozambique’s *Tchuma Tchato* Project come from trophy hunting, with a small portion coming from fishing licenses. Between US\$ 11,000 and 17,500/year are paid to communities; this makes up 34% of the annual trophy plus 34% of the license fees (Nimpuno, 2003). This is not a countrywide program as of yet, being confined to one hunting block along the southwest corner of the Cahora Bassa Reservoir linked to *Safaris de Mocambique* run by Piet Hougaard.²³⁶

9.5.5 Botswana Community Trust Program

Botswana’s hunting industry has a gross turnover of from US\$ 12.5 million/year (BWMA, 2001) (see analysis below in Section 9.6.3.4, Botswana Community

²³⁶ Piet Hougaard, Safari Operator, *Safaris de Mocambique*, *Tchuma Tchato* Community Project. mozamsaf@zol.co.zw. Hougaard sold this company in 2005 to a South Africa based company, “Destination 16 Degrees South”, Geoff Dean, P.O. Box 86, Hilton, 3245, South Africa, geoff@sleepyhollow.co.za.

Trust Program) to US\$ 15 million/year (TRAFFIC, 2001 *In: Baldus & Cauldwell, 2004*) to a high of US\$ 20 million/year (African Advisory Board, 2000a). Five Botswana “community multi-purpose areas” around the Okavango Delta and Chobe Game Reserve generate income from both hunting and eco-tourism. The revenue generated by hunting companies for these five communities in Botswana for 1999 was US\$ 1,696,272.00 (includes land rental, quota, wages, meat contributions, business grants, funeral assistance) (Peake, 1999 *In: African Advisory Board, 2000a*). It has been extremely difficult to obtain a breakdown of revenue to the communities from hunting versus eco-tourism or a breakdown at the level of each individual community. This results in the community receiving 8.5-13.6% of the gross turnover from the safari industry.

9.5.6 LIFE, Namibia, Nyae Nyae Conservancy

Namibia’s overseas trophy hunting is mostly on white-owned farms and was valued at US\$ 4.7 million in 1998 (African Advisory Board, 2000a) to US\$ 5 million (TRAFFIC, 2001 *In: Baldus & Cauldwell, 2004*). However, in 1998, the gross turnover of wildlife production and utilization in Namibia was US\$ 42 million (African Advisory Board, 2000a) from a combination of trophy hunting, live sales, game meat sales and biltong hunting, mostly on white farms, though increasingly in community conservancies. There also was/is some taxidermy.

The Living in a Finite Environment (LIFE) Project of Namibia, funded by USAID, started in the early 1990s to help create community conservancies run through the World Wildlife Fund (WWF) U.S. in collaboration with the Namibian Ministry of Environment and Tourism (MET) (see Section 9.6.3.5, LIFE, Namibia, Nyae Nyae Conservancy). Jones (1999a) provides an excellent historical overview of the process leading to the establishment of the LIFE Project. The Nyae Nyae Conservancy, a communal conservancy, obtains 100% of the conservancy’s income from trophy hunting. Additional money is made by

individuals from craft sales and running a campsite. Conservancy earnings were to be divided between membership (65%) to purchase livestock to boost food, meat and milk production, as well as to contribute to common property benefits from improvement in schools and water infrastructure to agriculture, and 35% to conservancy operations. This data was not broken down at the household level. Direct cash handouts have not always happened (Berger, 2003). Between 1998 and 2002 (five years), a total of US\$ 242,073 (\$N 1,694,511) was earned by the conservancy or an average of US\$ 48,414.5/year (Berger, 2003).

9.5.7 Selous Conservation Program (SCP), Tanzania

The 48,000 km² Selous Game Reserve (SGR) covering 5% of Tanzania's surface area (Baldus & Siege, 2002) was established in 1922. The history of the Selous and other similar reserves and parks, established during the colonial era and its impacts on local people, is described in Chapter 3, Section 3.6, THE END OF COLONIALISM AND THE ACCELERATION IN PHYSICAL SEPARATION OF AFRICANS FROM THEIR RESOURCES. The Selous Game Reserve consists of 44 hunting blocks with no core protected area (Baldus, Kibonde & Siege, 2003), while in 2006 there are 43 hunting blocks and four photographic safari areas (Kibonde, *pers. comm.*). This dispels the myth that wildlife in large numbers over vast areas can only survive in areas of complete protection, namely national parks.²³⁷ The Selous Game Reserve represents 35% of the hunting by clients and by value in Tanzania, which in 2001 was 480 clients averaging 15 days/safari in the Selous (Baldus & Cauldwell, 2004).

²³⁷ 47,500 km² subdivided into 47 blocks in eight administrative sectors; 43 blocks leased to hunting companies and four blocks (B1, K1, Y1 and Z1) reserved for non-consumptive photographic safaris (Baldus & Cauldwell, 2004).

“The Selous Conservation Program (SCP) was established in 1988 as a response to the destruction of wildlife during the later 1970s and early 1980s. It is a bilateral program between the governments of Tanzania (Department of Wildlife) and Germany. Its objectives are to safeguard the existence and ecological integrity of the Selous Game Reserve (SGR) as a conservation area, and to reduce significantly conflicts between the reserve and local populations by implementing village wildlife management and utilization on a sustainable basis (Baldus, 1991; Krischke & Lyamuya, 1991, *In: Gillingham, 1998* *In: Barrow, et al., 2000*). The project operates primarily as a conservation initiative, not a rural development program. It aims to encourage the direct involvement of rural people in wildlife management and conservation by offering tangible wildlife-related benefits (Baldus, 1991, Krischke & Lyamuya, 1991 *In: Gillingham, 1998* *In: Barrow, et al., 2000*). Buffer zones have been established around the reserve for the sustainable use and conservation of wildlife by local people. These buffer zones are located on agriculturally marginal lands which are unsuitable for cattle keeping due to tsetse fly (GTZ & Department of Wildlife, 1994 *In: Gillingham, 1998* *In: Barrow, et al., 2000*). The project works with 41 villages in five districts” (Gillingham, 1998 *In: Barrow, et al., 2000*).

Hahn and Kaggi (2001 *In: Baldus, et al., 2001*) indicate that this program has expanded to 57 villages, while the Wildlife Division (2003) indicates that 51 of 85 villages around the Selous are involved. Kaggi (2002) indicates that 57 out of 90 potential villages are participating.

The Selous Game Reserve (SGR) in Tanzania has increased its income from eco-tourism in the last ten years. Tourism has increased 15-fold over the last 15 years (six tourist camps in the northern sector of the reserve). Tourism contributes 10% to overall income and 20% of the “Selous 50% retention fund” income. Twenty hunting companies in 44 hunting blocks account for 90% of the income and 80% of the retention fund income (Baldus, *et al.*, 2003). Income is distributed as followed (Kibonde, 2004):

Where there is a retention scheme [in Selous Game Reserve (SGR)], the following fees are charged:

4. Game fees, block fees and professional hunters' fees:

- 50% Selous Game Reserve (SGR);
- 25% Tanzania Wildlife Protection Fund; and
- 25% Treasury.
 - a. 40% retained by treasury;
 - b. 35% Wildlife Division; and
 - c. 25% district councils = “25% retention fund”

5. Permit fees, conservation fees, observer fees:

- 50% Selous Game Reserve (SGR); and
- 50% Tanzania Wildlife Protection Fund supposed to run all tourist hunting (sport hunting) areas

6. Trophy handling fees:

- 100% Tanzania Wildlife Protection Fund.

- A part of the income from safari hunting is annually transferred to the respective district councils. Since the introduction of the retention scheme (1993), Selous Game Reserve (SGR) can retain 50% of its income for management. This “Selous 50% retention fund” consists of 50% of the game/trophy fees, hunting block fees and professional hunters’ fees and

50% of the permit, conservation and observer fees (Kibonde, *pers. comm.*; Kibonde, 2004). One third (33%) (e.g., US\$ 500,000) of this annual budget of about US\$ 1.5-2 million is spent outside the game reserve on 1) construction and maintenance of roads increasing transport of cash crops to markets, 2) improvement of communal facilities such as secondary schools, dispensaries and milling machines and 3) salaries of government scouts who stimulate the local economy with improved purchasing power (Hahn & Kaggi, 2001 *In:* Baldus, *et al.*, 2001). This money does not reach households other than through local game scouts. However, according to Baldus, *et al.* (2003), 11% of the “Selous 50% retention fund”/year is used for rural development outside of the game reserve, which from 1999-2002, a period of four years, amounted to US\$ 890,000 or US\$ 222,500/year out of an annual retention fund budget of US\$ 1.5-2 million. In 2003/04, the amount given to communities for development projects was 11% of an annual Selous budget of about US\$ 2 million or about US\$ 220,000/year (Kibonde, *pers. comm.*). It appears that US\$ 220,000/year is the most accurate figure. In 2005, with the end of GTZ support for the Selous, the government has drastically reduced its budget, no longer honoring the “Selous 50% retention fund” (Kibonde, *pers comm.*);²³⁸

- In 2001, another US\$ 41,327/year was obtained by 57 villages from the sale of wildlife meat, income from resident sport hunters, voluntary contributions from safari operators and concession fees from photographic tour operators (Hahn & Kaggi, 2001 *In:* Baldus, *et al.*, 2001); and
- Additionally, there is the “25% retention fund” (25% of 25% of game, block and professional hunter fees that go to the treasury). In the 1999/2000 season, this amounted to US\$ 150,000. This mostly goes to

²³⁸ Unfortunately after the Selous Conservation Program (SCP) ended in 2003 with a retention of US\$ 2.7 million, the retention amount was cut by more than 50% in the following year and to less than US\$ 1 million in 2005/06 (Baldus, 2005a *In:* Baldus, 2005b). The government obviously has other priorities.

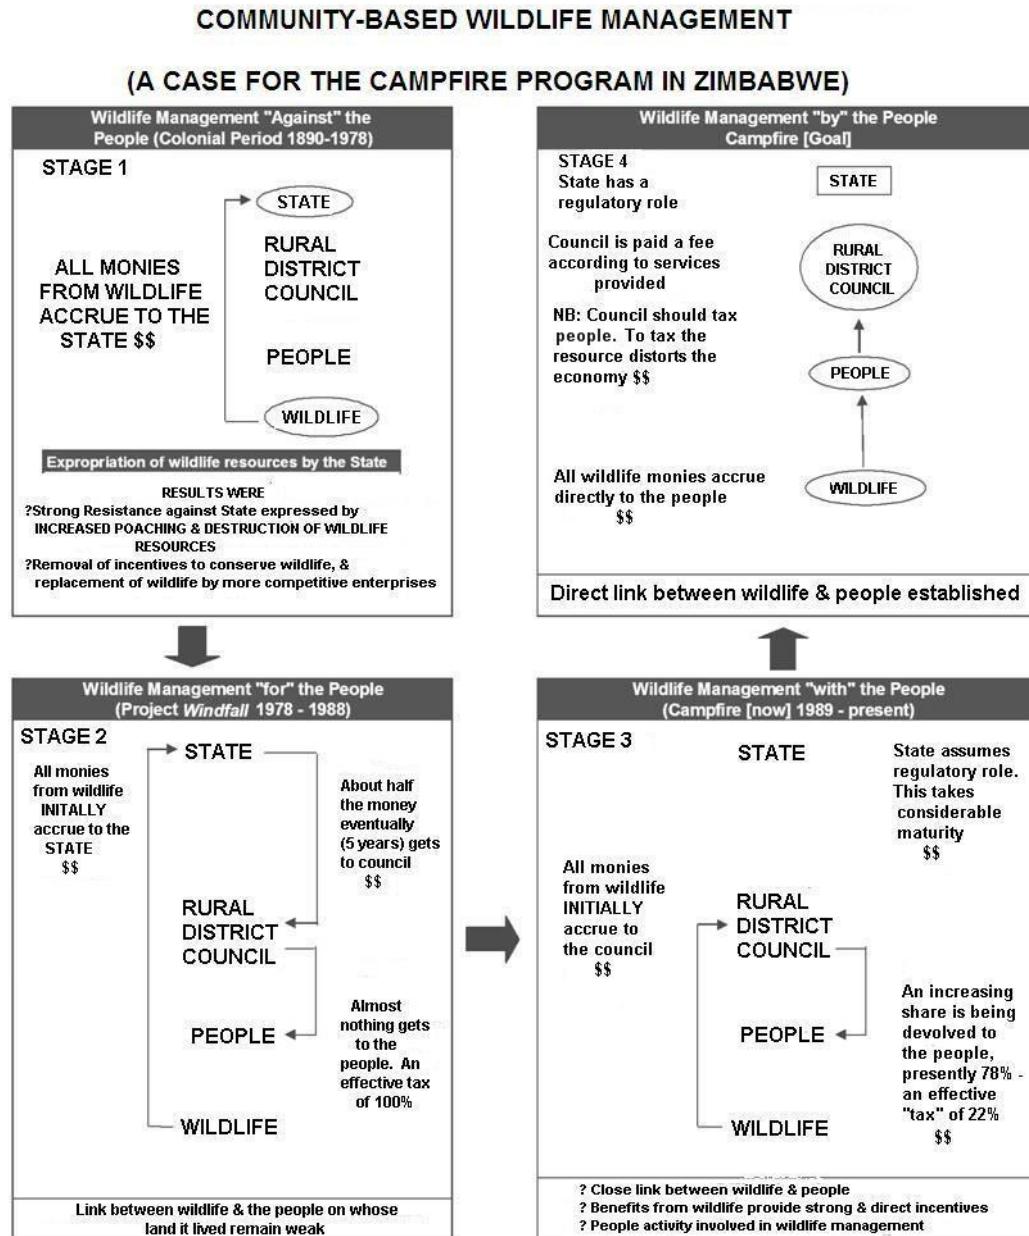

Rural District Councils (RDCs) and is rarely seen by the community let alone the household (Hahn & Kaggi, 2001; Siege, 2001a; 2001b all *In: Baldus, et al.*, 2001).

Therefore, in theory this amounted to a total of about US\$ 411,327 for community benefits in 2001.

9.6 EVOLUTION OF CBNRM IN AFRICA

The attached chart (Figure 9.1) shows the evolutionary stages in the devolution of authority in the CAMPFIRE process.

Though dates may differ, this is the evolution through which most of the older CBNRM programs have passed or are passing. Some newer programs have bypassed a given step as they learn from mistakes made in the older programs. However, most CBNRM programs are stuck in Stage 3, “Wildlife Management With the People”, and are held up in attempting to reach Stage 4, “Wildlife Management by the People” by a lack of trained people from the community to operate and manage the complex institutional arrangements, businesses and wildlife/resources at this stage and a reluctance by government to “let the resource go” for both philosophical and monetary reasons. Attaining resource and land tenure will be critical to communities reaching this final stage of devolution.

Source: Rigava & Chinhoyi (1997), with permission, WWF.

Figure 9.1: Stages towards devolution, community-based natural resource management (CBNRM), CAMPFIRE, Zimbabwe

9.6.1 Conservation/Wildlife Management against the People, Stage 1

As discussed in Chapter 3, the conservation policy of colonialism tended to expropriate large tracts of land from rural people for the establishment of protected areas, in addition to removing rural people's control and ownership over their wildlife and other natural resources, often to consolidate, usurp and monopolize the ivory trade from Africans. All money from wildlife went directly to the state. This disenfranchisement alienated Africans from their resources, their land, and the links to their ancestors and the spirit world. Most refused to accept this imposed dispossession, forcing them into accessing the resources clandestinely through "poaching". This made centralized management based on repression, "anti-poaching", an impossible task for the limited manpower and budgets of game departments.

This turned wildlife from a "common property" resource managed at a local level to an "open access" resource belonging to everyone, but being the responsibility of no one but the state, which was incapable of controlling access by its alienated people. Africans began mining wildlife as a short-term resource in favor of long-term investments in other economic sectors over which they had control, such as farming and livestock. Of course other factors also came into play such as 1) the human population explosion of the 20th century, 2) the corresponding increase in and cultural ties to livestock and 3) the soil characteristics of savanna environments, which require long periods of time and large areas of fallow for each hectare under cultivation, a practice that is disappearing (see Chapter 5) under the wave of humanity sweeping across the continent and moving the exploding population onto marginal agricultural land, which is often critical wildlife habitat. The net result, encroachment on and conversion of key wildlife habitat by this wave of human poverty, must be considered the main threat to wildlife in the 21st century – not poaching!

9.6.1.1 Zambia

Things did not necessarily improve for rural Africans after independence from colonial governments, with many nations continuing with colonial policies and centralized control of natural resources. Zambia is a fine example of “Wildlife Management Against the People”, which has been well documented.

“Immediately after independence in 1964, Kenneth Kaunda began to make radio broadcasts and public speeches about the need to protect wildlife. The wildlife bill of 1968 closely followed colonial laws, while conferring even more authority over wildlife by central government. By 1971, 8 statutory instruments were declared that detailed laws regarding trophies, hunting licenses, protected animals, and legal hunting methods. In the same year Kaunda also signed an order creating 32 Game Management Areas (GMAs), and his minister made a motion to the National Assembly to declare a system of 18 national parks within Zambia. Rural Africans were allowed to hunt, but the methods of hunting, where they could hunt, and the requirement of a license resulted in a system that legally excluded most Zambians from using wildlife (still the case in 2007)...As in the colonial era, one way for rural Africans to express their discontent with the loss of land to protected areas, and the loss of hunting rights, was to poach...Even though Kaunda favored strict enforcement of game laws, the UNIP (United National Independence Party) government that had come into power under the rights of locals to hunt, did not make enforcement of game laws a priority” (Gibson, 1999).

Threatened by increased strength of opposition parties, by 1972 Kaunda declared a one-party state, concentrating power in the office of the president. Wildlife came under increasing pressure with even less law enforcement than under a multiparty state (Gibson, 1999).

Under the new electoral rules, members of parliament were more responsible to their constituency than under multiparty rule. Local officials and local party backing was required if a candidate wished to gain support in the primary

elections and in the general elections candidates were elected by the local voters who began to expect that their member of parliament would support their demands. Constituents frequently voted out parliamentarians who failed to deliver local benefits. During the same time frame, a dramatic fall in copper prices by 1975 led to government policies causing inflation. Maize previously accounted for over 70% of marketed agricultural production. Government decreased producer prices of maize, favoring the urban consumer, which resulted in a 50% decline in maize production from 1975-84, forcing many households to cease producing for the market. Smallholder incomes declined by 58% from 1974-83. Urban incomes also declined. Civil servants, representing 67% of the formal sector employment, saw price increases outpace government wage increases (Gibson, 1999).

At the same time, rural Zambians detested wildlife laws, believing that they had a right to hunt and that safari hunting, not hunting for the pot, endangered wildlife populations. They saw the only beneficiaries from game laws and reserves/parks as white tourists, white hunters, white lodge owners and government, all at the expense of the rural population. A growing international demand for wildlife products, from petrodollars increasing incomes in many Asian/Middle East countries, resulted in increasing demand and value on ivory and rhino horn. Decreased domestic incomes increased the domestic game meat market. Significant budget cuts in the Game Department (National Parks and Wildlife Service - NPWS) resulted in decreased manpower and operational means to enforce wildlife laws and conduct anti-poaching campaigns. Only the contributions of the white dominated Wildlife Conservation Society (WCS) of Zambia, safari companies, Save the Rhino Trust and Honorary Rangers sustained anti-poaching efforts (Gibson, 1999). The pressure on wildlife at all levels began to increase:

- Foreign exchange (FOREX) was badly needed to pay off debts and pay for imported products; and
- Rural areas that had depended on remittances from family working in the mines began to rely more on wildlife as a source of food.

The net result was a wave of poaching across the country. Ivory prices increased six times between the early 1970s and late 80s. It is estimated that by the mid-1980s, elephant populations were reduced by about 75% from about 100,000 to between 15,000-25,000, the majority of the population and thus reduction being in the Luangwa Valley (African Advisory Board, 2000b) (see Chapter 5, Section 3.7.3, Open Access Resources among the Valley Bisa). During all of this time, ivory and rhino horn were legally marketed items. By the early 1980s, licenses for hunting elephant and rhino were stopped to protect the legal slaughter of these animals for the international horn and ivory market. The illegal slaughter only accelerated. Things got completely out of control, until most of the rhino and elephant in Zambia were exterminated. The international ban on ivory in the early 1990s provided a short-term stopgap to protect elephant (SCI African Chapter, 1996) (Table 9.3):

Table 9.3 Elephant declines, Luangwa Valley		
YEAR	ELEPHANT NUMBERS	SOURCE
1973	100,000	Caughley & Goddard (1975)
1978	45,000	
1983	25,000	
1990	15,000	Child & Clayton (2002)

Source: DeGeorges *In: SCI African Chapter (1996)*.

Elephant are beginning to recover with current estimates at over 25,000 (Faddy, *pers. comm.*, *In: African Advisory Board, 2000b*).

The exact change in the black rhino population over time is difficult to determine due to conflicting numbers given by various surveys. There were most probably

about 2,000 rhinos in Zambia, with estimates ranging from 1,000 to 7,000 (Faddy, *pers. comm.* In: SCI African Chapter, 1996). What is known is that the black rhino is almost gone, though remnant individuals have been recorded in the dissected and difficult to traverse area south of the South Luangwa National Park (Faddy, *pers. comm.* In: SCI African Chapter, 1996). Child and Clayton (2002) estimate that by the mid-1980s there were less than 100 in the Luangwa Valley.

Uncontrolled hunting areas (open for non-resident hunters²³⁹) were rapidly depleted of game. Likewise, there has been a gradual deterioration of wildlife in GMAs (Game Management Areas). Rural residents, military and police, businessmen and politicians all joined in this free-for-all. Even game department officials were implicated (Potgieter, 1995).

By 1995, there were only four Grade A hunting blocks out of 22 GMAs, which still offered superlative quality big game hunting, including lion, leopard and buffalo (Table 9.4). GMAs cover an area of about 150,000 km² (ZAWA, 1999). It is said that these areas are in their present state, due to protection and good management practices by the better safari operators (SCI African Chapter, 1996).

As indicated below, a number of hunting blocks changed categories between 1992 and 1996, in a downward direction. ZAWA (1999) calculated that

“the current use of trophy animals to sustain the safari industry is limited to 19 hunting blocks, of which 14 account for 90% of the total income”.

Closure of hunting between 2001 and mid-2003 exacerbated this problem.

²³⁹ A resident hunter is someone usually living within the GMA as opposed to non-resident citizen hunters living outside the GMA, often in town.

Table 9.4: Prime hunting blocks, Zambia in 1995

GAME MANAGEMENT AREAS (GMAs)			
<u>Grade A</u>	<u>Grade B</u>	<u>Grade C</u>	<u>Depleted</u>
Nyampala	Chanjuzi	Bilili/Nkala	West Zambezi Upper
Sichifulo	Lower Luano	Busanga	Lunga Luswishi
Luawato	Chifunda	Mumbwa East	
Mulobezi	Kasonso	West Petuake	
	Mumbwa West	Rufunsa	
	Mwanya	Sandwe	
	Lower Lupande	West Zambezi Lower	
		Upper Lupande	
		West Musalangu	

Note: Grade A: best blocks descending to Depleted being worst block with regard to game populations.

Source: DeGeorges *In: SCI African Chapter (1996).*

Note: Lumimba divided into Chanjuzi (north) and Mwayna (south), Munyamadzi = Nyampala, Lupande divided into: Upper and Lower Lupande, Mumbwa divided into East and West Mumbwa, West Zambezi divided into Upper and Lower West Zambezi Game Management Areas (GMAs). In 2005, the following blocks have been subdivided: Mulobezi, Lunga Luswishi, Lower Lupande, Nkala/Bbilili comprised of two GMAs now split to be Nkala and Bbilili, Chikwa/Fulaza (Simwanza, 2005b.)

Note: In 2006 ranked as Prime, Secondary, Understocked and Depleted (Manning, 2006), as well as Specialized where any of the three species lechwe, sitatunga and tsessebe are restricted in their distribution. Manning (2006) states that “it is likely that many of Zambia’s hunting blocks require downgrading”.

9.6.1.2 Kifluku Farm, Laikipia, Kenya

See Chapter 11, Section 11.11.9.2, Impact of donor driven conservation on private lands for a detailed discussion of Clive and George Aggate of Kifluku Farm, Laikipia Kenya.

Although there are similarities, there are also major differences between Kenya and Tanzania, which have resulted in wildlife living under more favorable conditions in Tanzania – at least until now (see Chapter 3):

1. In both Kenya and Tanzania, prior to the 1890s, tsetse fly/wildlife habitat had been pushed back to the point that it only made up about 33% of Tanzania's landmass – no specific data for Kenya;
2. In both countries, a series of catastrophes resulted in a major die-off of people and livestock, allowing wildlife and the bush to come back starting in the 1890s;
3. In both cases, people were compressed to make way for European settlers, parks and hunting blocks;
4. Human population densities were somewhat lower in Tanzania and failed tsetse fly eradication schemes and both colonial and post-independence *Ujama'a* village schemes concentrated people, allowing tsetse fly to spread along with the wildlife;
5. A big difference was that the Tanzanian government retained ownership of the land and wildlife and that it was in its economic self-interest to see wildlife and related habitat survive;
6. In 1977, the World Bank forced the closure of hunting in Kenya, taking away the value of game reserves to government. It is believed that many were turned into parks and others into group ranches;
7. Kenya gave ownership of the habitat to the people - based on a World Bank encouraged group ranching scheme, which it could be argued impoverished the Maasai as it cut off transhumance and sedentarized them - giving local communities ownership of the land but not ownership over the wildlife. Thus, the people opted out of wildlife except in Laikipia and Machakos, where white Kenyans with a different vision of the landscape saw wildlife as a key component along with a few privately black owned cooperative ranches. Minimal use of wildlife has been allowed (e.g., some

game cropping, commercial bird shooting for sport, eco-tourism) of insignificant consequence to landowners; and

8. However, today in Tanzania, human populations and poverty are increasing. Simanjiro is a good example of a key wildlife area disappearing under small-scale farmers, as land is leased to commercial farms and the “politics of despair” emerges as people return from the hopeless cities and begin poaching, charcoal making, farming and honey collecting, while their cattle are over-grazing - whatever it takes to survive (see Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”).

East Africa has among the fastest growing human populations in the world at 3.5%/year (Roe, *et al.*, 2000). Population increases between 1950 and 2000 alone in East Africa took on the following dimensions (for detail see Chapter 5, Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY):

HUMAN POPULATION			
Country/Area	1950	2000	Times Increase/% Annual Growth Rate
Kenya	6,121,184	29,985,839	4.9/3.2
Tanzania	7,934,924	33,065,142	4.2/2.9
Uganda	5,521,758	23,248,553	4.2/2.9

Source: USBC (2004) with permission USBC + public domain.

Thus, with increasing population pressures, the proposed community run Wildlife Management Areas (WMAs) in Tanzania (see Section 9.6.3.6, SCP Program), if they become a reality and result in true devolution, will basically mean ownership of the land and wildlife by the communities, as opposed to decentralization where government still retains control. This may be the long-term hope for the survival of wildlife and its habitat in Tanzania. Returning full ownership of wildlife to landowners in Kenya may stop the current rapid extinction of wildlife/habitat

across the country outside of parks and private/cooperative ranches of Laikipia and Machakos.

9.6.1.3 Manyeleti Game Reserve, South Africa

The area comprising the 22,750 ha “Big 5” Manyeleti Game Reserve, among other property, was originally demarcated as white farms lasting over the period from about 1869 to the late 1950s/early 1960s when the land was purchased by the Apartheid government’s South African Development Trust to create black homelands. The original inhabitants, who made a living from hunting, were forced into becoming farm workers on the white farms. A portion of this land was set aside as a “black game reserve” run by the Gazankulu homeland government and called Manyeleti, the “place of the stars”. With the change in governments in 1994 and in accordance with the constitution, the land was transferred to the current custodian, the Northern (now Limpopo) Province government (Mahoney & van Zyl, 2001). Peripheral communities on the western boundary of the Manyeleti Game Reserve won a 2002 land claim over the reserve. Situated on the western boundary of the Manyeleti Game Reserve are eight rural communities within two tribal authority (TA) areas - seven in the Mnisi TA area and one in the Machangana TA area. Manyeleti is bordered on its eastern boundary by the Kruger National Park, on the south by the Sabi Sand Game Reserve and on the north by the Timbavati Game Reserve. It is still managed by the Limpopo Parks and Tourism Department, with little say by local communities over how the reserve and the resources are to be used. The reserve to date is primarily for foreign tourists staying in private lodges. In 2001, there were three concession areas and 74 beds, which were marketed to primarily European tourists. A total of 60-70% of the beds were filled per night (mid-luxury) at between US\$ 92-132²⁴⁰ (Rand 700 – 1,000)/night/person, all-inclusive (Mahoney

²⁴⁰ FXConverter – 164 Currency Converter, www.oanda.com/convert/classic

& van Zyl, 2001). In 2005, the Tintswalo Safari Lodge charged between US\$ 754-1,062 (Rand 4,900-6,900)/person/night depending on the accommodation and the season.²⁴¹

Even as facilities improve, local livelihoods appear to be little impacted by such development. A 2005 survey based on 330 questionnaires of which 50 were distributed to adults in Dixie village, 80 in Hlavekisa village, 60 in Gottenberg village and 140 in Welverdiend village, found that: 1) the majority of the people interviewed wanted to be involved in running development activities in the reserve, 2) the majority saw the reserve as a place where African wildlife was kept for the benefit of the rich, 3) they wanted access to various natural resources within the reserve and 4) regardless of age or education there was no statistical difference with the majority of people believing that poaching in the reserve was a result of poverty and hunger. The student researcher was dissuaded by the Kruger National Park socio-ecologist from quantifying economic benefits to the community due to the issue's political sensitivity (Masango, 2005).

Can natural areas in South Africa, or for that matter across the subcontinent, survive if rural people are alienated from the rural landscapes being imposed on them by an urban majority? On one hand, the urban majority, desiring to escape from the concrete jungles of the big cities, perceives nature as a pristine environment, untouched by human hands, a nirvana bathed in warmth and beauty. On the other, rural impoverished subsistence-living communities perceive a need to live from the resources contained in these natural systems and are alienated from urban perceptions and desires of rural landscapes imposed on them. This is resulting in a clash of cultures and livelihoods across Sub-Saharan Africa, as the urban world, controlling both wealth and politics, wants exclusion zones.

²⁴¹ http://www.krugerpark.org/Premier_Safari_Lodges-travel/pricing_manyeleti-safari-tintswalo-lodge.html

However, in creating these areas, they are placing themselves in direct conflict with rural livelihoods and in the long run are jeopardizing biodiversity by forcing rural people to poach since legal access is not possible. As discussed, once clandestine access to resources occurs, their sustainable management becomes difficult and they will likely be mined for short-term gain out of anger, frustration and the need to survive, with the ultimate result being habitat and resource degradation; a loss to both local communities and to the world's urban majority. Rather than being lose/lose, the situation could be win/win by integrating the needs of both groups into these areas.

9.6.2 Conservation/Wildlife Management for the People, Stage 2

Due to concern about the increasing deterioration of the African environment, governments passed legislation creating conservation and extension agencies. The situation did not improve as the governments did not have the capacity to enforce what they determined (imposed) were good environmental practices for Africa's real natural resource managers, the millions of small-scale farmers and pastoralists (Murphree, 2001 *In: Baldus, et al.*, 2001). In fact, in many instances, the practices imposed on rural Africans further deteriorated the environment (see Chapters 3-8). By now, the governments in desperation decided that some benefits from wildlife should be shared with local communities in an attempt to co-opt them into Western ideas of conservation being put forth by the newly independent governments.

9.6.2.1 Operation Windfall, Zimbabwe

In the precursor to CAMPFIRE, “Operation Windfall”, (Wildlife Industries New Development For All) 1978-88 (Figure 9.1), money from wildlife went directly to the state, took five years to get down to local government (district councils), while

almost nothing got to the people; in effect a 100% tax was levied against producer communities (Rigava & Chinoyi, 1997).

9.6.2.2 ADMADE, Zambia

“An important workshop held in 1993 in the Luangwa Valley (The Lupande Development Workshop) resulted in a Presidential Directive that led to the creation of the Administrative Management Design for Game Management Areas (ADMADE) and the Luangwa Integrated Development Project (LIRD). In the same year Zambia provided policy support for CWM (CBNRM) through its Policy for Wildlife in Zambia, which established an administrative and financial framework for the further development of the ADMADE program” (IUCN/SASUSG, 1997).

ADMADE is a "bastard child" lying between this and the next stage.

“The ADMADE program was a counter by NPWS (National Parks and Wildlife Service – now Zambia Wildlife Authority (ZAWA) to the LIRD (Luangwa Integrated Resource Development Project funded by Norwegian Agency for International Development (NORAD) – a Western Donor) program to increase NPWS control over wildlife, while shielding these efforts from political interference. It was established in 1987. The main goals were 1) increase the department’s revenue and shield it from government control, 2) Increase the number of NPWS staff through employment of community wildlife scouts, and 3) Create popular support for ADMADE” (Gibson 1999).

In essence, Dzingirai (2004) argues that throughout much of CBNRM until today, the state has used the CBNRM concept across Sub-Saharan Africa to create

“physical infrastructure such as game guards, anti poaching units, purchase of vehicle, all aimed at further restricting local access to local resources while strengthening the state and private business’ renewed grip on them” (Dzingirai, 2003; Munro, 1998; Schroeder, 1999 all *In:* Dzingirai, 2004).

All ADMADE revenue went through the wildlife department's "revolving fund", from which it was not only hard for the Wildlife Management Sub-Authorities (WMSAs) to obtain money, but for which the European Union (EU) believed +/- US\$ 1 million to be unaccounted for in 1994/95 (SCI African Chapter, 1996). There was a complete lack of transparency, the fund never having had an external audit. USAID believes that many of the funds destined for communities were diverted for administrative purposes (SCI African Chapter, 1996) or worse into the pockets of the bureaucratic elites. This appears to be a continuing problem with the disbursement of these funds being held up because of "institutional problems" (Nyambe & Nkhata, 2001 *In:* Johnson, 2004 *In:* Fabricius *et al.*, 2004). When money did make it down to the WMSA, most of it was used to the benefit of the chief, his village and a few technicians (e.g. teachers and nurses) handpicked by the chief to do his bidding (DeGeorges, 1992a). The "modern chief" no longer represented his people but himself! The chief used income from ADMADE to maintain his power, consolidating his links with powerful outsiders, and to develop local patron client relationships (Marks, 2005 *In:* Lyman & Child, 2005). The central role of traditional authority (chiefs) in decision-making and revenue distribution is being challenged (IUCN/SASUSG, 1997) and as is seen in this case study is being addressed with attempts at creating more democratic institutions. Chiefs from the WMSAs sat on a NPWS technical committee and recommended the selection of preferred concessionaires. These recommendations were ignored, as safari operators were chosen by the NPWS. There were many scandals and eventually court cases regarding the former that may have helped shut down hunting from 2001-mid 2003 (Section 9.8.5.1, ADMADE). With an overly-centralized one-party state, NPWS was used to create employment through a patronage system to family members, but also patronage and kickbacks linked to the awarding of hunting blocks (Child, McKean, Kiss, Munthali, Jones, Mtsambiwa, Castley, Patton Magome, Pangeti, Fearnhead, Johnson & Chilikusha 2004 *In:* Child, B., 2004a), which during the Chiluba era was largely controlled

by the Indian business community who were rewarded for supporting the President and his government. This ultimately led to what Bond, *et al.* (2004 *In:* Child, B. 2004a) identified as a “political and bureaucratic leadership in collusion with a closed and uncompetitive private sector”.

Government game cropping to feed the villages never met its annual quota and rarely got to outlying villages other than the chief's, with most of the meat being sold off in urban centers (DeGeorges, 1992a; Marks, 2005 *In:* Lyman & Child, 2005). Traditional hunters, their needs and possible role in wildlife management, have been systematically ignored by government and Dale Lewis, who was sponsored by USAID through WCS²⁴² (DeGeorges, 1992a). The principal author remembers, during this evaluation, a woman running up to the vehicle with a bowl of dried mice, mice outbreaks in Zambia and Malawi providing a major source of protein, even being sold along the roadside in Malawi, with four to five roasted mice on skewers. She said,

“This is all we have to eat. The government cropping program is getting nothing to the outlying villages” (DeGeorges, 1992a).

9.6.3 Conservation/Wildlife Management with the People, Stage 3

This strategy became known as “community participation”. This is where we are **today**, with most CBNRM programs such as CAMPFIRE in Zimbabwe, Botswana Community Trust Program, the Selous Conservation Program (SCP) in Tanzania, etc. This strategy recognizes the power of Africa's rural peoples to shape the continent's environmental future. It recognizes traditional knowledge, “indigenous technical knowledge” (Murphree 2001 *In:* Baldus, *et al.*, 2001), but rarely uses this knowledge in making management decisions. It recognizes rural Africa's cultural, spiritual and ancestral ties to the land, wildlife and other

²⁴² Wildlife Conservation Society of the New York Zoological Society

resources, but generally fails to integrate these needs into the management of the areas, opting for material rewards to change attitudes.

The successes of this strategy, to date, are isolated, externally initiated and heavily subsidized by the outside world. The broad CBNRM picture in Sub-Saharan Africa remains one where successes stand as islands in a sea of initiatives, where performance rarely matches promise and is sometimes abysmal (Murphree, 2001 *In: Baldus, et al.*, 2001). The lack of generalized advance in stemming negative trends in Africa's environmental status has unleashed disillusionment for CBNRM.

These programs are mostly top-down with minimal input from the "producer communities", the villages that co-exist with wildlife.

9.6.3.1 CAMPFIRE, Zimbabwe

In the 1960s, Zimbabwe experienced a radical shift in policy over wildlife from protectionism to conservation through sustainable use. The concept of game ranching took hold and with the advent of the safari industry in the 1960s, wildlife began having a comparative/competitive economic advantage on white owned ranches over other land uses (e.g., cattle). This led to the 1975 Parks and Wildlife Act, which "confers privileges on owners or occupiers of alienated land as custodians of wildlife, fish and plants". "Owners or occupiers of alienated land" were designated "appropriate authorities" over wildlife, effectively making farms and ranches into proprietorial wildlife units, combining "ownership", management, cost and benefit. Then in 1982, the government amended the Parks and Wildlife Act, allowing the minister to appoint a rural district council "to be the appropriate authority for such area of Communal Land as may be specified".

This amendment, in theory, eliminated discrimination between farmers on private lands and communal land farmers. The 1989 wildlife policy went on to say

“outside the Parks and Wildlife Estate, government views wildlife as a resource capable of complementing domestic livestock and will favor neither one above the other in the development of the country. It will rather allow economic processes to determine the outcome of competition”. (Government of Zimbabwe, 1989:7 *In:* Murphree, 1997).

The statement asserts what Aldo Leopold said 60 years ago,

“Game management is a form of agriculture”, (Leopold, 1933 *In:* Murphree, 1997).

Thus, the groundwork for CAMPFIRE was laid out.

The average armchair conservationist waves the CAMPFIRE banner saying “power to the rural people”, supposing that CAMPFIRE represents the rural citizens of Zimbabwe with links to wildlife. However, this is the farthest from the truth. Certainly, this has been the case with the sport hunting community, who have supported the philosophical concept of wildlife benefiting people, but who have rarely delved into what CAMPFIRE is and what CAMPFIRE does for rural people and their attitudes towards wildlife. The CAMPFIRE Association is an umbrella body of Rural District Councils (RDCs) (local government) given appropriate authority over wildlife since communities are not legal entities (Child, 1995).

Post-independence amendments to the District Councils Act and the Rural District Councils (RDCs) Act of 1988 allowed Rural District Councils (RDCs) to lease land and utilize natural resources on behalf of their communal land constituencies.

The sub-structures of RDCs as set up after independence are as follows (Child, 1995; Murphree, 1997):

- At the lowest tier are the Village Development Committees (VIDCOs) comprised of about 100-150 households or 1,000 people. Each village is represented by an elected VIDCO, with the VIDCO chairperson representing the village at the ward level; and
- The next tier is the Ward Development Committee (WADCO), comprised of VIDCOs. There are up to six to ten villages represented at a ward level. Each WADCO elects a councilor to the RDC, which may also have councilors elected from commercial farm areas within the district. The size of each council will vary according to the district's population, but generally fall within the range of 12-28 councilors.

VIDCOs and WADCOs were imposed and often did not follow traditionally established boundaries of territory and membership. VIDCOs and WADCOs are essentially planning and administrative units. They do not have legal rights to ownership or exploitation of land and resources and can only act in this capacity as delegated units of RDCs. RDCs often preside over areas, which are highly heterogeneous in population densities and resource endowments (Murphree, 1997).

By 1996, there were 56 RDCs of which 26 had appropriate authority and were designated as CAMPFIRE areas, while 13 had trophy hunting as a major focus (SCI Africa Chapter, 1996). Those CAMPFIRE areas where trophy hunting is important tend to be peripheral to a national park or another natural area that serves as a core protected area to produce wildlife, the overflow of game being hunted in the CAMPFIRE area (Sparrow, *pers comm.*; Cumming, 2004 *In:* Child, B., 2004a). Cumming (2004 *In:* Child, B., 2004a) explains that this is also

true for the community Game Management Areas (GMAs) of Zambia, hunting blocks in northern Cameroon, and the Wildlife Management Areas (WMAs) and Controlled Hunting Areas (CHAs) of Botswana.

Wildlife may not be so much conserved in the communal areas as harvested when populations of wildlife wander out of parks, some providing income such as elephant, lion and buffalo from trophy hunting, while others such as antelope may be taken for meat by local hunters or as trophies by overseas hunters. Conservation thus does not take place directly on the communal land which tends to be over-populated with people, but in the core area or just adjacent to it on a small portion of the communal land with approval of local community members – the core area serving as a protected area where wildlife can reproduce and populations can grow. In essence, these complexes function as an IUCN biosphere reserve: a core protected area with multiple use peripheral areas.

The Department of Wildlife and National Parks under the Ministry of Environment and Tourism retains ultimate authority over wildlife if it is misused. The CAMPFIRE Association is an umbrella body of RDCs consisting of a board of 13 people with a chairman and a first and second vice president. An association “Chief Executive Officer” has been hired as a staff member, along with support staff. Wildlife management committees exist at the level of the RDCs, wards (representing up to ten villages) and villages. Service providers (NGOs) include the:

- World Wildlife Fund (WWF) Zimbabwe, which assists with wildlife monitoring and quota setting;
- Zimbabwe Trust (ZIMTRUST) assisting with capacity building; and
- African Resources Trust (ART) (ART, 2002) assisting with international lobbying.

Murphree (1997) believes that the biggest weakness of CAMPFIRE is the RDCs rather, than producer communities, at the ward level having legal control over wildlife.

“It perpetuates the legal discrimination between access rights to wildlife accorded to farmers in the commercial sector and those accorded to communal land farmers. Finally, by placing devolution at the discretion of councils, it has led to the wide variation in the Program's degree of success as councils have responded to their commitment in different ways” (Murphree, 1997).

Hasler (1999) raises the above as a major design flaw in CAMPFIRE.

In many instances, the RDCs have failed to distribute benefits from wildlife to a lower level. Thus in many cases, the “decentralization” of CAMPFIRE has become the “recentralization” of a district-level elite. The result has been ignorance of or hostility to the CAMPFIRE program, mistrust of the councils concerned, increasing intolerance of wildlife in localities and a continued lack of communal environmental controls (Murphree, 1997). District councils depend on and therefore intercept the revenues from CAMPFIRE, further reducing the already minimal impact that these revenues can have (Koch, 2004 *In: Fabricius, et al.*, 2004).

“What we had, and continue to have therefore, was not genuine involvement but rather a decentralization of despotism” (Dzingirai, 2004).

Sibanda (2004 *In:* Fabricius, *et al.*, 2004) also believes that the distribution of benefits is often inequitable since the policy of giving income and other benefits to the villages (ward) where the animal is killed during the hunting season (May–October) may not take into account the people in rainy season dispersal areas (November–April) who must also tolerate the same wildlife. They are often far removed from the hunting block, may have had to tolerate crop raiding by that animal, but receive no compensation.

Junge (2004) believes that this failure in full devolution to producer communities is a major reason why land uses in many CAMPFIRE areas are incompatible with wildlife (e.g., in-migration, extension of cropping and increased livestock numbers).

As stated earlier and as is restated a number of times, CAMPFIRE, as originally structured, and many similar CBNRM programs in Africa, while generating common property benefits generally fail to improve household livelihoods. Murombedzi (1994 *In:* Murphree, 1997) suggests that

“under small-holder agricultural conditions prevailing in communal lands cattle are a main form of household accumulation and that unless CAMPFIRE revenues at household levels are at levels sufficient to off-set the perceived loss of the accumulative potential of livestock the Program is likely to encounter opposition at these levels. His research suggests that this opposition is likely to be particularly strong in wealthier households”.

CAMPFIRE was meant to be a dynamic process with eventual negotiated devolution of authority over wildlife to the producer community (Murphree, 1997). It was an “African solution to African problems”. CAMPFIRE was designed so that money generated from wildlife, 90% through hunting (60% from trophy hunted elephants), would go back into uplifting rural communities living

among the wildlife in return for their cooperation in protecting wildlife and its critical habitat (Child, 1995; SCI African Chapter, 1996). However,

“since 1995 CAMPFIRE has been viewed as a ‘middle-aged’ social movement – missing out the crucial stage of adulthood. It is at this stage where many of the flaws of the program could, and should, have been ironed out – i.e. mechanisms should have been developed to ensure the devolution of ownership to the ward and village level, thereby breathing life into the ‘community-based’ part of the program. Instead the state, at its various levels, retained control and ownership, and District Councils remain the seat of ‘Appropriate Authority’ over wildlife” (Hasler, 1999 *In: Roe & Jack, 2001*).

9.6.3.2 *Tchuma Tchato*, Mozambique

Prior to the imposition of safari hunting on the Bawa community of Tete Province, traditional de facto management was adequate, guided by the spirit mediums as intermediaries especially to *Sekwati*, the spirit of the land, and the lion spirit.

Safaris de Mocambique, a private hunting concern, started operating in what is known as “Block 1” in 1989 during the Mozambican civil war and was immediately confronted with uncontrolled commercial poaching that devastated the game populations (Edwards, 1994). The hunting block is in the southwest corner of the Cahora Bassa Reservoir, virtually cut off from Mozambique by water on the north and east, and bounded on the west by Zimbabwean hunting blocks. This is the only hunting block where the community conservation program *Tchuma Tchato*, “our wealth”, takes place and at the time was the only hunting block in Mozambique with a CBNRM program.

Namanha and Abacar (1993) from the Mozambican game department in interviews with villagers state that the latter saw themselves as having no ownership over wildlife, saw poaching as a way of earning money and viewed wildlife as a pest. Namanha and Abacar (1993) also state that the ivory ban had contributed to increased poaching as the illegal demand increased and recommended the practice of trophy hunting of elephant, as was taking place in CAMPFIRE schemes across the border, to the Mozambican government.

Similarly, Edwards (1994) decided that the only hope of deterring poaching was a management plan with benefits to the local people. In 1994, the *Tchuma Tchato* started as the first CBNRM project in Mozambique, relying on its next-door neighbor Zimbabwe's CAMPFIRE experience. The project was supported by the Ford Foundation,²⁴³ but jointly managed by IUCN-Rosa (Regional Office, Southern Africa) in Harare and the National Forestry and Wildlife Directorate (DNFFB) in Maputo. Later on, fund management was relocated to the Provincial Direction of Agriculture and its CBNRM unit. Since 1994, Ford spent almost US\$ 1.8 million on the project through seven different grants. Most grants were given directly to the unit created within the provincial government for CBNRM (Nimpuno, 2003)

The donor funded *Tchuma Tchato* program centralized de jure (legal) control over wildlife and other resources, resulting in “aborted devolution” undermining a functioning traditional and local management system that had previously assured sustainable levels of resource use (Johnson, 2004 *In: Fabricius, et al., 2004*). The *Tchuma Tchato* program was designed to and used by government as a vehicle for institutionalizing capacity within the bureaucracy, resulting in increased state and local bureaucratic intervention. However, it was presented to the community as a

²⁴³ Ford Foundation, Southern Africa, P.O. Box 30953, Braamfontein 2017, Johannesburg, South Africa, Tel: 27-11-276-1200, Ford-johannesburg@Fordfound.org, www.Fordfound.org/global/office.index.cfm?office=Johannesburg

means of resolving conflict and empowering the community's control over safari hunting operations. Although the community was to be aided in the formation of a community-based management institution to which the state would devolve certain levels of authority to manage natural resources, this never happened. (Johnson, 2004 *In: Fabricius, et al.*, 2004).

The government and safari operator marginalized the community with regards to traditional control and access to resources in the area. The safari operator, rather than negotiate controlled access by the community, used his empowerment by government to exclude and alienate the local people from the area through repression. Much of the support for this program that increasingly marginalized the local community through centralization was funded by the Ford Foundation, which by 2001 was pulling out, leaving the expensive government conservation unit on the verge of collapse (Johnson, 2004 *In: Fabricius, et al.*, 2004).

The safari operator first paid his fees to government. Money was then distributed directly to the producer community (village), which is considered a level of government. The village determined how to spend these benefits from hunting (Nimpuno, 2003). However, by 2001, rather than funding individual communities, the money was handled centrally by a common commission representing the entire area (Nimpuno, 2003). This appears to be a step in the wrong direction desired in the devolution of authority. Villagers have little say with regards to their selection of a private sector partner, setting quotas (both safari, and traditional of which there are none), etc., all of which are controlled by the government. They are however involved in anti-poaching. As in most "top-down" narrowly focused CBNRM programs, where local needs are not integrated into the management plan, especially traditional hunting, how successful can anti-poaching be? One has to wonder how effective these community game guards are in arresting their relatives who have no legal right to hunt?

Ultimately, according to Johnson (2004 *In: Fabricius, et al., 2004*), the community's perception of the *Tchuma Tchato* program became negative for a number of reasons: 1) revenue streams were diverted by government conservation agents for both law enforcement and for conservation agent lodging, 2) the Mozambican government, as all over Africa, taxes the wildlife resources by retaining significant amounts of trophy and concession fees and 3) the government empowered the safari operator to use repression, as well as to undertake anti-poaching without first negotiating access by the community into the area for various resources, including wildlife. Community game guards that supposedly represented community management and control were brought under control of government and ordered to enforce laws against their fellow community members resulting in division and dissent. Poaching increased and the government wildlife post built on a hill near Bawa village, while first being seen as a sign of development, had come to be seen as a sign of repressive and uncalled for state intervention (Mugabe & Murphree, 2000 *In: Johnson, 2004 In: Fabricius, et al., 2004*).

9.6.3.3 Cullman Hurt Community Wildlife Project, Tanzania

Robin Hurt was ahead of his time in Tanzania, starting this program in the early 1990s before most people were even thinking of implicating rural communities in conservation in East Africa. This began under his first safari company, which he sold, now known as Tanzania Game Trackers (TGT)/Wengert Windrose Safaris, which has continued his ideas under the Friedkin Conservation Fund.²⁴⁴

Under Hurt's current company, Robin Hurt Safaris, the Cullman Hurt Community Wildlife Project, is very top-down with money being controlled by a project staff.

²⁴⁴ A community conservation fund linked to the safari companies of Tanzania Game Trackers and Wengert-Windrose Safaris, Arusha, Tanzania named after the owner of these two companies, an American based out of Texas, also info@legendaryadventure.com and www.legendaryadventures.com

Village committees, elected by popular vote determine how to spend their share of the money, with funds being spent, after informing local government, either through purchase of materials and/or employment of local workers under contract. A disadvantage of this is that the communities do not learn fiscal responsibility. On the other hand, this avoids mismanagement and corruption so typical of many CBNRM programs. Robin Hurt (*pers. comm.*) does not believe many of these communities are ready to properly manage money, lacking trained bookkeepers and accountants. He may very well be right, given the current level of training and education of most community members/staff at this time, and the history of fund mismanagement in other CBNRM programs (e.g., ADMADE, Botswana Trust and CAMPFIRE)!

9.6.3.4 Botswana Community Trust Program

The Botswana approach combines rights to obtain quotas and hunting licenses from the Department of Wildlife and National Parks (DWNP) with rights to obtain leases over land for commercial purposes from land boards. The Policy on Wildlife Conservation of 1986 called for the greater involvement of local people in wildlife management and utilization, and for rural people to gain greater benefits from wildlife use, but does not say how this will be achieved.

“The Wildlife, Conservation and National Parks Act of 1992 provides for the declaration of Wildlife Management Areas (WMAs) and Controlled Hunting Areas (CHAs) and provides for permission for wildlife use on communal land to be given by Tribal Land Boards. The Tribal Land Act of 1968 enables Tribal Land Boards to give out leases for commercial purposes. Policy directives, such as the SAVINGRAM (a Botswana Government term for an internal memo) on community tourism and hunting development, provide for leases over hunting and tourism to be given to communities who form a representative legal entity. Rights are dependent upon designation of an area as a community hunting area otherwise the lease is negotiated between the Land Board and the private sector directly. District level government

agencies play a significant role in the process of a community negotiating its joint venture. According to the Joint Venture Guidelines, communities have to wait for endorsement of the joint venture approach by the District Development Committee. The District Council is assigned a role in negotiating with the private sector on behalf of the community. The Joint Venture Guidelines make it clear that: 'Wildlife remains the property of the State, and although wildlife management is to be decentralized, wildlife utilization and any form of off-take will be subject to the DWNP's decisions regarding the quota for each area' (IUCN/SASUSG, 1997)".

Jones (1999a) provides a detailed background of history and legislation leading to the Botswana Community Trust Program.

The legal entity referred to above was the trust. In the Botswana Community Trust Program, a very strict set of rules was established by the Ministry of Trade and Industry (Peake, 2001): 1) decisions as to which "community areas" would be allocated to which villages were made in advance by the government, though generally villages within or close to each area were selected, 2) the community-based organization (CBO) had to be in the form of a representative and accountable legal entity for the community living in or near the Wildlife Management Areas (WMAs) in question; a "trust" registered with the registrar of societies, 3) to create a trust, each group of villages set up an interim management committee selected at a *kgotla* (village meeting), in the presence of district level officials of DWNP and the district land board, 4) once the community registered its trust, the trust was given a 15-year lease²⁴⁵ of the controlled hunting area (CHA) by the land authority for a nominal rental and the trust was allocated an off-take quota by DWNP, 5) the trust could enter into contract with commercial operators for these purposes through a tender process or it could use the resources for subsistence purposes and 6) the first private sector sublease or joint venture

²⁴⁵ Fabricius, *et al.* (2002) indicate a ten year lease

contract was one year only, the second for one year, the third for three years and the rest for five years with renewal options. At the end of each contract, the trust had the option to renew the contract with the private sector or to go out to tender again.

As WMAs have come up for re-tendering, they have been reclassified as multiple use areas. Those turned over to community trusts were reclassified as Community Management Areas (CMAs) (SCI African Chapter, 1996):

- Five community managed wildlife utilization in livestock areas; and
- Six community managed wildlife utilization areas (community multi-purpose areas and community photographic areas).

The first community trust was in the Chobe enclave in 1994, comprising five villages. Such community trusts have stronger legal proprietorship than wards in CAMPFIRE (Fabricius, *et al.*, 2001) but as is seen, are far from having achieved full devolution rights by government. There are many overlapping tenure regimes. Government still owns and controls wildlife but as noted above access rights to wildlife and land can be leased from government, while grazing on floodplains outside the buffalo fence (e.g., outside the Moremi Game Reserve/Okavango Delta) is treated as communal property and fishing and veld products are often treated as “open access” (Hasler, 1998 *In:* Fabricius, *et al.*, 2001).

Communities have a very tenuous hold over their control of wildlife at the good will of the government. The president can remove the wildlife management area status protecting wildlife as a land use (IUCN/SASUSG, 1997). As noted and is seen below, the DWNP and even the vice-president can close hunting for various species without a solid biological basis and for what appear to be political

motives. On January 30, 2001 the permanent secretary of the Ministry of Local Government issued a “savingram” that “with immediate effect” all revenues earned by community-based organisations in the country from the use of wildlife and natural resources, should be handed over to district councils. The funds were to be administered by the district councils (local government) on behalf of the communities, “in consultation with the affected communities”. By implication, the funds were also to be shared among other communities elsewhere in each district. The reasons given in the savingram for this directive may be summarized as follows (Bell, 2000):

- Wildlife is a national asset and benefits from it should be shared by the state as a whole and not be confined to the communities living with it. Wildlife is likened to diamonds in this sense;
- The present system, where benefits from wildlife in community areas are allocated to the local community trust, is discriminatory, since any job opportunities resulting are reserved for members of the local community concerned, while others are excluded;
- Funds derived from wildlife under the existing system are misused by the community trusts which are often unable to produce audited accounts; and
- The intention that the funds be used by local communities for community development is not working or is duplicating development efforts on the part of the district councils.

The directive to transfer funds derived from wildlife in the community areas to the district councils was a 180-degree reversal of policy. This attempt has been foiled for the moment. However, it is expected that such “tug of wars” between governments, both local and national, and between government and rural communities, will be part of the evolutionary process of CBNRM over the next ten to 20 years as communities struggle to take back control over their resources, not only in Botswana but also across Sub-Saharan Africa. A fine example is the

struggle by the San (Basarwa) to take back the Central Kalahari Game Reserve (CKGR), which is currently playing out in the Botswana courts (see Chapter 3, Section 3.9.2, Eco-Genocide and the San of the Central Kalahari Game Reserve (CKGR), Botswana).²⁴⁶ Jones and Murphree (2004 *In: Child, B., 2004a*) conclude that since USAID support for the Natural Resources Management Program (NRMP) ended (1989-1999), government has not filled the gap left by the donors, leaving a weak institutional support base for CBNRM. This questions their long-term commitment to CBNRM in Botswana.

Government meddling in community affairs continues. In 2001-2002, the government, which sets quotas, significantly reduced quotas, a decision that was based on politics and not good science.

Under ministerial powers, Clause 64 of the Wildlife Conservation Act, the minister has the power to abolish a species from the hunting quota without notifying anyone. On February 5, 2001, the Minister Of Commerce and industry declared lion hunting closed for one year, without giving any reason. Lion hunting remained closed in 2004 as this was being written. The closure of lion hunting could cost the safari industry, and thus communities, US\$ 1.26 million/year or 10% of the total annual income from hunting (BWMA, 2001). The loss of 24 elephants on quota in two hunting areas, as well as the other animals in these areas, amounts to more than US\$ 1.6 million loss of turnover. When added to the loss due to the closure of lion hunting, the industry will face a reduction of some US\$ 2.86 million, or BWP (Pula) 15.7 million (22.8% of gross turnover) at the 2001 exchange rate (BWMA, 2001). This implies a gross turnover of US\$ 12.5 million/year from safari hunting.

In 2002, hunting was closed for sable, sitatunga and reedbuck (Peake, 2002) and will likely never reopen unless hunting companies support and fund extensive

²⁴⁶ San win case in December 2006

surveys to determine population numbers (Peake, 2006). Leopard, kudu and lechwe quotas were reduced. The only quota remaining static was the elephant quota (Peake, 2002). The reduction in trophy quotas was followed by massive increases in trophy fees and export fees (Myburgh, *pers. comm.*). The Vice President, Ian Khama, appears to be behind much of these closures. He is alleged to be closely allied with individuals within the animal rights movements such as Pieter Kat (a lion researcher) and Derek Joubert (a film maker) with support from the England-based animal rights group Born Free Foundation²⁴⁷ (2002). He is also alleged to have significant shares in the eco-tourism company, Wilderness Safaris, admitting on its website that it is anti-hunting and losing as much as US\$ 300,000/year in revenue from the closure of hunting in its concessions (Wilderness Safaris, 2006), where both hunting and photographic safaris are permitted in the same concession.

In the Okavango Delta of Botswana, 12 lion were on the hunting quota/year²⁴⁸ out of a population of between 1,178 and 1,698 lions in 1999 (Winterbach, Winterbach, Sechele & Kat, 2001).²⁴⁹ According to Paul Funston (2004),

“This was an off-take of about 1% per year. What is true is that the Botswana government’s policy of paid compensation of stock losses due to large carnivore predation had failed, and that regardless of the compensation large numbers of lions were still being killed annually for preying on livestock. Even so it is estimated that Problem Animal Control (PAC) and safari hunting combined were only accounting for 5% of Botswana’s estimated 4000 lions annually, which is probably sustainable at current human densities”.

²⁴⁷ Animal rights group Born Free, FREEPOST RCC1862, Horsham RH13 5BR; 3, Grove House, Foundry Lane, Horsham, West Sussex, RH13 5PL. <http://www.bornfree.org.uk/index.shtml>

²⁴⁸ Only 12 lion/year number in Okavango Delta (Winterbach, *pers comm.* In: SCI Africa Office, 1999).

²⁴⁹ Estimated lion population 1,178-1,698 in 1999 and 1,189-1,668 in 1998 (Winterbach, *et al.*, 2001).

It is obvious that the decision to close lion hunting is a political agenda of Vice President Khama and Western animal rights groups. There certainly has been no consultation with rural communities who will determine the future of lion. Likewise, the decision to stop lion hunting appears to have gone over the heads of the wildlife department.

Rumors abound that if and when Ian Khama becomes president, hunting will be closed in the Okavango Delta and Chobe, these areas being used exclusively for tourism, even though many hunting operations run both safari hunting and eco-tourism with lodges for both on the same concession. This allows maximization of profits from wildlife. What does the future hold for hunting and sustainable use in Botswana? With each year quotas are cut, trophy fees and other taxes go up and it becomes more and more difficult for safari operators to cover their costs and earn a living, while remaining competitive in the market place. Many people see hunting phasing out in the Okavango Delta and Chobe. Some believe that elephant hunting will continue as this gains significant revenue for the communities and there is an over-abundance of elephant in northern Botswana. They believe that in the future, most plains game hunting will take place on game ranches such as those being developed in the Ghanzi and Tuli blocks (Peake, *pers. comm.*). None of this has anything to do with empowering communities to take control over their own resources or destinies. It is top-down and heavily influenced by foreign outside forces. At the end of the day, the local people and wildlife lose.

The Department of Wildlife and National Parks (DWNP) is under the Ministry of Commerce and Industry, and has not supported the decision, recommending a lion quota every year (Winterbach, *pers. comm.*). Christian Winterbach (*pers. comm.*) knows an individual who spoke directly to Khama and was told that although he personally does not like hunting, he understands its role in conservation. While maybe not being the reason for the closure of lion hunting in 2001, Winterbach

(*pers. comm.*) believes that the US\$ 500,000 offered by a wealthy sport hunter and backer of one of the major safari operations to Botswana for lion research over a five year period if they kept lion hunting opened was seen by Khama as an attempt to bribe him and the country. To demonstrate that Khama and his country could not be bought is believed to be the primary reason that Khama over-ruled the game department's recommended lion quota from 2001-2004. Salopek (2001) accuses well-known lion hunter, Steve Chancellor, a backer of Rann Safaris, as well as former President George Bush Sr., former Vice President Dan Quayle and Persian Gulf War hero Gen. Norman Schwarzkopf of pressurizing the government to lift the ban on lion hunting. The exact truth, be it pressure from the animal rights and/or pressure from the hunting community, is likely to be known only to a select few such as Mr. Khama. It should be noted that in 2005, lion hunting re-opened with one lion per major concession area (Causey, 2005) in the Okavango/Chobe area, amounting to 20 lion in total. Safari operators in other parts of the country are complaining. In addition, Problem Animal Control (PAC) of lion in livestock areas has been opened up, these policies being supported by a recent meeting of regional lion researchers over Botswana's lions. However, further analysis at the level of populations/management units was recommended (Funston, *pers. comm.*). Limited lion hunting continued in 2006. In October 2007, lion hunting in Botswana has been closed again until further notice, the reason being given as the large number of PAC lions being killed (van der Merwe, 2007).

9.6.3.5 LIFE, Namibia, Nyae Nyae Conservancy

Historical Setting

Commercial farms and ranches were granted wildlife user rights in 1967, followed by the 1991 policy of the Ministry of Environment and Tourism creating

conservancies on commercial farms and ranches and finally on communal lands as promulgated in the 1996 Nature Conservation Act (Fabricius, *et al.*, 2001).

The LIFE Program is one of the latest CBNRM programs to start up, having the distinct advantage of learning from older CBNRM programs in Southern Africa. It appears to be a fairly bottoms-up program. Institutional constraints, as opposed to government, are at the basis of its frailties.

The Minister Of Environment and Tourism retains regulatory oversight, with the ultimate rights to withdraw conditions or recognition of the communal conservancy. Conservancy legislation confers user rights over wildlife and tourism resources to the community conservancy but not ownership of the land or resources (Hulme & Murphree, 1999 *In:* Fabricius, *et al.*, 2001). One shortcoming is that the current system of communal lands is “open access” in which other groups can move into a conservancy area, settle on the land and use the resources (see Section 6.1.5.2, Decentralization and creation of pastoral associations in West Africa, and Chapter 9, Section 9.7.2.1, Devolution through policy reform, land and resource tenure). A “white paper on land reform”, if passed, will provide community conservancies exclusive tenure and the ability to apply for “ownership” of their land (Fabricius, *et al.*, 2001) (see Chapter 6, Section 6.1.5.2, Decentralization and creation of pastoral associations in West Africa). According to Long (2004), communities through conservancies still have limited rights over wildlife and de jure land rights remain in the hands of central government.

By 2001, the 15 registered communal conservancies managed over 200,000 head of wildlife in 40,000 km², expecting to increase to 49 conservancies and 100,000 people with 34 emerging conservancies covering approximately 60,000 km² (Child, 2005 *In:* Lyman & Child, 2005).

Nyae Nyae

While the Ju|'Hoansi (San) of Naye Naye lost about 90% of their original 90,688 km² (35,000 mi²) during colonialism (Weaver & Skyer, 2003) (see Chapter 3, Section 3.8.1 Land Compression Among the Last Hunters and Gatherers, Ju|'Hoansi of Nyae Nyae, Eastern Bushmanland, Namibia), in 1998, Nyae Nyae was the first communal area in Namibia to be registered as a conservancy with the Ministry of Environment and Tourism (MET). This occurred under legislation passed in 1996, making the Nyae Nyae community a pioneer in the institutionalization of CBNRM in Namibia. Wildlife has been translocated into the area and 14 dedicated water points for game have been established compared to less than five that were operational in the early 1990s (Weaver & Skyer, 2003), most of this coming about from USAID funding with some support from the private sector. The community is involved in wildlife monitoring and in contracting out to a safari operator whom they select.²⁵⁰ It appears that the MET still establishes trophy hunting quotas, as the communities do not have the capacity. To date nothing has been done to address traditional hunting, so poaching continues (Berger, 2003). According to Arnold (*pers. comm.*), traditional hunting is now allowed using traditional weapons (e.g., bow and poisoned arrow, and spears) but not modern firearms. Though it still needs capacity building, there exists a “conservancy management board” consisting of three members each from four districts and a four person management committee and conservancy staff (Berger, 2003). Concerns have been raised by both Berger (2003) and Wiessner (1999:3 *In:* Hitchcock, 2003a) concerning elitism developing between those employed by the conservancy and the unemployed from the community. Disharmony from a small percentage of the community employed by ecotourism is raised as a threat to its sustainability (Watkin, 2007).

²⁵⁰ In most of Africa, government still select private sector with little or no say from rural communities.

9.6.3.6 SCP, Tanzania

The Selous Conservation Program (SCP) is midway with regard to empowering communities. Although the community has been given some responsibilities, full devolution is far from being achieved. About 50% of the money currently made from safari hunting in the Selous is controlled by the SCP of which about 11%-33% of this 50% [see Section 9.5.7, Selous Conservation Program (SCP), Tanzania] is used for community development outside of the reserve such as road maintenance, schools, dispensaries, milling machines, and game scout salaries who come from the area (Hahn & Kaggi, 2001 *In: Baldus, et al., 2001*), but not directly to producer communities. Another 25% of the 25% of game fees, block fees and professional hunters' fees go to local district councils, but as noted, little of this is believed to reach rural communities.

Though accepted by the Wildlife Division, the “*Revised Draft Policy and Management Plan for Tourist Hunting*” has never been implemented (Department of Wildlife, 1995 *In: Baldus & Cauldwell, 2004*). It would solve many of the current shortcomings within the safari industry, such as transparency through tendering, direct negotiation between communities and safari operators, community participation in quota setting and community management of revenue from hunting. It even devised a plan for the sharing of revenue from trophy hunting:

Wildlife Management Areas (WMAs):

- 75% of revenue goes to the local community for management and community development;
- 15% goes to district councils for support of local government wildlife staffs; and
- 10% goes to the Tanzania Wildlife Protection Fund for administration.

Game Reserves:

- 50% goes to game reserve retention to meet management costs;
- 10% goes to the Wildlife Protection Fund for administration;
- 15% goes to the district councils as an opportunity cost of the game reserves; and
- 25% goes to the treasury

The 1998 Wildlife Policy of Tanzania (WPT) transfers management authority over WMAs [some Game Control Areas (GCAs) and all Open Areas] to local communities. The Wildlife Division retains control over hunting in game reserves. WMA guidelines have been established (Wildlife Division, 2003). The WPT defines a WMA as “an area set aside by village governments for the purpose of biological natural resource conservation” (Junge, 2004). However, a new wildlife act must still be passed, revising the Wildlife Conservation Act No. 12 of 1974, so that WMAs can be fully promulgated and rural communities can obtain full user rights (Baldus, Kaggi & Ngoti, 2004; Junge, 2004). The 1997 National Environmental Policy and the 1998 National Forest Policy compliment the WPT in supporting strong decentralization of management of natural resources down to the village level (Junge, 2004).

As of 2001, the SCP was the major area for the development of WMAs, with 51 of 85 villages around the Selous having created “pilot” WMAs. In theory, the Authorized Associations (AAs) – see description below) can authorize (Wildlife Division, 2003):

- Traditional hunting quotas;
- Resident hunting;
- Tourist (overseas) hunting;
- Non-consumptive tourism (photo safaris);

- Live animal capture;
- Tree harvesting;
- Bee resources (honey collection); and
- Fishing.

Mining, game cropping and game farming/ranching are not allowed. A major problem for many local residents is that they cannot afford the hunting license fees, even though they are at below market prices, thus resident hunting becomes reserved primarily for richer urban-dwelling Tanzanians and non-citizen residents (Majamba, 2001).

The pilot WMAs are given an annual meat hunting quota harvested by the villages and sold to the community to raise money for community projects – individuals at household level do not appear to gain income. There is one village contracted to a tourism lodge. Resident sport hunters can pay to hunt though the main revenue from this hunting goes to the district council (Siege, 2001b; Zacharia & Kaihula, 2001). There are pilot schemes where villages set an additional fee (Siege, 2001b).

Until overseas trophy hunting is phased in, it is unlikely that CBNRM will be a significant addition to the household income (Siege, 2001b), but to date the government has not allowed this to happen. According to Kaggi (2004), the main reason is that none of the pilot WMAs are registered and that they have not been allowed to start economic operations.

It appears that the WMA process is slow and tedious: too bureaucratic as opposed to streamlined. There are 12 institutions involved in the management of a WMA depending on its location: 1) Authorized Associations (AAs), 2) village councils, 3) village assembly, 4) district council – local government, 5) district natural

resources advisory body, 6) Wildlife Division of the Ministry of Natural Resources and Tourism (MNRT), 7) Tanzania National Parks (TANAPA), 9) Ngorongoro Conservation Area Authority (NCAA), 10) Tanzania Wildlife Research Institute (TAWIRI)—responsible for the wildlife monitoring unit, 11) NGOs and 12) individual investors (e.g., private sector) (Wildlife Division, 2003).

The AA council consists of three members from each participating village of the proposed WMA and is responsible for managing the WMA and employing game scouts. The AA central committee consists of ten elected members from the AA council, which has executive duties. The AA board consists of five members elected from the AA committee, who act as trustees and enter into agreements with the private sector (Wildlife Division, 2003).

There are seven major steps in creating a WMA: 1) inform villagers, 2) village council (VC) recommends potential WMA area to village assembly (VA),²⁵¹ 3) villagers through village assembly form a registered community-based organization (CBO) with a constitution and “strategic plan”, 4) develop land use management plan approved by village assembly, followed by an environmental assessment (EA) of the plan, 5) draft a general management plan and a resource management zone plan, 6) CBO submits application to director of wildlife through district council, 7) director of wildlife determines if the CBO can be an AA and have a WMA to manage, 8) the director of wildlife forwards his recommendation and application to minister and 9) minister declares area a WMA and issues a certificate of authorization and publishes the AA in the gazette (Wildlife Division, 2003)

At present, the Wildlife Division has not granted any of the “pilot” WMAs authorized association (AA) status and therefore none can go into joint venture

²⁵¹ VC and VA village government institutions with VA consisting of all adults over age 18 and VC consisting of 15-25 elected members of VA

with the private sector for tourist safari hunting. Only one WMA, JUKUMU,²⁵² has managed a joint venture with a tourist lodge (Kaggi, 2004).

“Restricted by the Wildlife Department to an annual hunting quota for bushmeat, JUKUMU can hardly cover its costs for the protection of the area. The Government earns good money from tourist hunting (sport hunting) in Gonabis, but they do not seem to be prepared to share it with the owners of the land. Together with other villages in five districts around the Selous Game Reserve (SGR), all participants of a pilot scheme, JUKUMU is struggling for survival. The Government has not yet finally decided whether it will replace its conservation policy of ‘fences and fines’ with the integration of rural communities into a new, more people-based conservation strategy” (Hahn, 2005 *In:* Baldus, 2005b).

The real money will come when the JUKUMU WMA is fully registered, receiving “wildlife user rights” under the law that allows tendering the hunting and tourism rights in Gonabis estimated at a value of US\$/year of 100,000 to 200,000 to the community. Like most pilot WMAs, the communities know this and their patience is running out (Rustagi, 2005).

Ashley, Mdoe and Reynolds (2002 *In:* LWAG/DFID 2002) state major constraints to the success of the Jukumu Society, including:

- Regulations still not in place to permit local wildlife based businesses;
- Most of time spent meeting WMA policies and not on enterprise development;
- Wildlife being used for communal income and not local economic development, or household level opportunities;

²⁵² Jukumu is an association of 22 villages collectively managing the area of Gonabis covering 250 km² of alluvial floodplain, serving as a dry season grazing area for wildlife from the Selous Game Reserve (Rustagi, 2005).

- Jukumu Society, which will manage WMA, is remote from local government;
- Trophy hunting has large barriers to entry by rural community;
- Selous is a fly-in luxury destination with few opportunities for kiosks, craft centers, cultural shows, etc.;
- Highest tourism/hunting potential inside Selous Game Reserve (SGR) not on community land;
- Far removed from markets for wildlife linked products such as skins and meat; and
- Socialist legacy of Tanzania causes suspicion of individual entrepreneurship.

Will communities be allowed to control tourist safari hunting, since as the income from hunting is spread around, many of the current profits made by the Wildlife Division will accrue to the WMAs, thus giving a smaller slice of the pie to the government? Thus,

“despite the alleged commitment to community involvement and participation through the Wildlife Policy, in practice, the WD (Wildlife Division) has not adhered to its own policy and legal framework...Consequently, the development of WMAs is seriously delayed. There is no progress on development of an effective schedule for sharing of benefits from tourist hunting (sport hunting) with the local communities on whose land hunting takes place. There is a general hesitation among outfitters to accept the WMA concept. It is possible that much of the delay in the development of WMAs is the result of a negative high-level influence by some hunting operators, who reportedly have influence with the Government to block the allocation process” (World Bank, 2005).

DPG (2005) draws similar conclusions with regard to some safari operators refusing to accept the WMA concept.

Safari operators, some of whom have had hunting concessions for up to 25 years, fear change, especially corruption going from central to the local level, plus the potential loss of income if they have to tender for concessions, providing fair market prices to communities and government. Currently, safari operators pay only US\$ 7,500/year/hunting concession as a block fee, the market value of a concession lease after deduction of fixed and movable assets being conservatively US\$ 50,000/year or US\$ 150,000-200,000/5-year lease (Baldus & Cauldwell, 2004). Tendering would force them to increase the share of profits from this and other charges with the communities. Corruption between village leaders and hunting outfitters has occurred in some pilot WMAs; one reason the Wildlife Division has retained full control over the outfitters and their quota allocations (Baldus & Cauldwell, 2004), and a major reason for the need to create transparent processes from accounting to wildlife monitoring.

Some of the larger safari companies such as Robin Hurt Safaris, TGT/WWS and Raul Ramoni's consortium are known to have some community programs mainly providing common property benefits through a trophy top-off fee charged to hunting clients. However, most companies provide

“mere window dressing and are not taken to task as the requirements set by the Wildlife Division are particularly vague in this regard...They prefer a paternalistic approach rather than true empowerment of the communities to manage wildlife” (Baldus & Cauldwell, 2004).

Another reason many safari operators do not wish change is that an estimated US\$ 1 million in interest might be lost in money collected in advance from clients (initial 50% advance payment six to eight months prior to the hunt and the remainder of the daily rate two months prior to the hunt) all of which can be banked and collect interest. Currently, only the US\$ 7,500/year block fee is paid in advance (10% of the payment to the Wildlife Division); 27% being paid on arrival of the client and the purchase of a permit and 63% at the end of the

hunting season, the deadline being April 30th of the following year (e.g. for the season of 2005 beginning in July, final payments due on or before April 30th, 2006) (Baldus & Cauldwell, 2004). Changes in revenue sharing could impact this hidden income of safari operators. Meanwhile the WMA process sits in limbo.

In mid-2007, the safari industry has been thrown into turmoil, with rumors of corruption in both government and the private sector being rift and from Tanzania Government Notice 159 of June 29th 2007 (URT, 2007) passed by parliament that increases block fees to US\$ 40-50,000/year, and trophy fees especially of flagship species such as lion and leopard from US\$ 2,500 to US\$ 12,000, and elephant from US\$ 4,500 to US\$ 15,000 (US\$ 30,000 if bow hunted). These increases occurred after safari operators had marketed and sold their hunts. If these fees are retained, hunting in Tanzania will become even more expensive in possibly the most expensive country in Africa to hunt, with the likelihood that a percentage of these fees will be passed on to the client and a percentage will cut into the safari operator's profit margin. Time will tell if Tanzania can remain competitive in this market niche, and if there are enough wealthy clients willing to pay such fees. Since the Government Notice that would have increased government fees from US\$ 10 million to US\$ 27 million/year, the safari operators have negotiated government fees down to US\$ 18 million/year (Kibonde, *pers. comm.*).

The biggest shortcomings of the WMA process under "The Wildlife Policy of Tanzania" of March 1998 are (Shauri, 1999):

- **State retains ownership of wildlife.** State-centered wildlife conservation is unsympathetic to the needs and concerns of the local people, resulting in a militaristic approach to management, which heightens conflicts. The failure of buffer zone initiatives to engender genuine community participation in wildlife conservation is partly related to the centralized top-down nature of and land use planning in wildlife management;

- **WMA procedures too bureaucratic.** The procedures for creating WMAs are considered too lengthy, leading to unnecessary delays becoming bogged down in various levels of bureaucratic red tape. Until this process is complete, the community has no right to access and benefit from its wildlife;
- **Communities lack technical skills.** The communities also lack technical skills to manage these areas and the wildlife;
- **Lack of political will** by the Wildlife Division to truly empower the communities;
- **National Land Policy**, while recognizing resource tenure conflicts over the haphazard allocation of traditional rangeland for large-scale agriculture and the danger this poses to wildlife, it does not recognize, clarify and secure customary land rights in law; and
- **National Parks Ordinance of 1959** gives the president power to declare national parks, thereby extinguishing customary rights. There is also concern that this policy will be used to further expand state land at the expense of customary land in creating wildlife corridors, dispersal areas and buffer zones – the latest battlefield.

Similarly, LWAG/DFID (2002) states that the complexity, cost and time to become approved as a WMA in Tanzania or a conservancy in Namibia acts as a barrier to entry of communities into taking back and managing their wildlife and other resources. This includes lengthy and detailed financial plans, management plans, land use plans and business plans with five-year budgets and forecasts. Baldus, *et al.* (2004) explain that the regulations are so complicated that one needs to be a “professor” to understand them. They conclude that establishing a WMA is more difficult than requirements for government protected areas including: management plans required of WMAs which most game reserves do not have, environmental impact statements which most roads and game scout

stations in government game reserves do not require a certificate of land not required in the WMA regulations and yet to be given to a single village in the whole of Tanzania. Many private sector operators, let alone less sophisticated rural communities, would have a difficult time providing all these inputs. Baldus, *et al.* (2004) believe that too much bureaucracy slows down the process and discourages target communities. They are concerned that the very cautious “pilot phase” could take decades, in effect creating a moratorium on the creation of new WMAs, while many pilot WMAs have been active for a number of years around the Selous, though none yet have full user rights that can serve as test models.

“Villages have already waited 15 years to see CBC (Community Based Conservation)²⁵³ become a reality in Tanzania. Within such a time span a child is born, is brought up and will nearly have completed its education. How far have the WMA ‘children’ developed in those years? Has the mother allowed them to take off their nappies? Has the father allowed them to use their abilities and earn money for themselves” (Baldus, *et al.*, 2004).

LWAG/DFID (2002) recommended streamlining these processes. Unless rural communities can make full use of and gain maximum benefits from their wildlife resources, CBNRM risks failing in Tanzania (Junge, 2002). Similarly, across the spectrum, de la Harpe, *et al.*, (2004 *In:* Child, 2004a) conclude for CBNRM in general that “a common example is the requirement for communities to have detailed land-use plans before they can begin wildlife management, when few parks have management plans to the same standard”.

Some concern exists that the top-down WMA process could turn rural communities into dependent clients of the conservation agencies as opposed to empowering the communities to take more control over their lives and the management of their wildlife and other natural resources.

²⁵³ Same as CBNRM

Mbarnoti (2004) concludes that

“community scepticism in establishment of Wildlife Management Areas (WMAs) in the Maasai rangelands revolves around lack of transparency, corruption, misguided policies, mistrust, etc. Often, the Question is; But who will really benefit from WMAs???, and/or Is this not a new malicious approach in which the Maasai will end up losers??? This is what people think and say”.

In 2000 a meeting was held in the village of Loibor Siret, with surrounding villages of the Simanjiro District from the wildlife dispersal area east of Tarangire National Park. In attendance were AWF²⁵⁴, TAWIRI, TANAPA and the local Member of Parliament. Already, the people in this dispersal area were wary of the WMAs being an underhanded way of pushing people off their land. Planned in advance, after much pomp and ceremony by AWF and government officials, the morani jumped up with spears and knobkerries and chased these people across the river. Since that date, they have refused to collaborate with AWF (Mbarnoti, *pers. comm.*) Research by Igoe & Croucher (2006) supports these concerns, demonstrating how communities around Tarangire National Park (TNP) have been coerced by African Wildlife Foundation (AWF), “officially designated by the Tanzanian government to oversee the establishment of WMAs in northeastern Tanzania”) and the Wildlife Division into forming Burunge WMA, located on the northwestern side of the park. This has resulted in the eviction of people from the WMA, and mainly brought benefits to safari operators, the Wildlife Division and a few village elites, while meeting the agenda of AWF for fundraising and to form wildlife corridors connecting the major parks of Maasailand.

How well has this program worked so far? Benson Obdiel Kibonde (*pers. comm.*), chief warden of the Selous Game Reserve (SGR), explained that about

²⁵⁴ African Wildlife Foundation, 1400 Sixteenth Street, N.W., Suite 120, Washington, D.C. 20036, U.S.A., Tel: +1 202 939 3333, Fax: +1 202 939 3332, email: africanwildlife@awf.org, <http://www.awf.org/>

37.5% of the Selous's annual budget (about US\$ 750,000 of a US\$ 2 million/year budget) and 45% of the manpower (300 game scouts patrolling 118 days/game scout/year) are used for anti-poaching. Wildlife is being defended, not managed. What this also implies is that "common property" benefits will not stop individuals from trying to gain income at the level of the household. The current level of devolution that puts the majority of the Selous' income in the hands of the government and private sector is unacceptable to communities. These constraints plus likely cultural ties to wildlife through hunting guilds that exist (Kibonde, *pers. comm.*) in the Selous area imply that traditional hunters, *murumba*, for personal gain will continue to hunt illegally unless they are integrated into the management of the Selous and its WMAs. Other resource users (fishermen, honey collectors, loggers, charcoal makers, etc.), trying to raise money at the household level will also continue to "poach" resources until integrated into the management of the Selous Game Reserve (SGR) and other protected areas of Tanzania. As already discussed, just as importantly, may be the feeling of and eventual legal ownership by communities over both the land and wildlife within their WMA. This concept could even extend into the Selous Game Reserve (SGR) that may need to be subdivided into management units protected by local communities, possibly overlaying traditional pre-reserve village territories over the current Selous boundaries.

Placing so much emphasis on anti-poaching takes away from other priorities such as community liaison, wildlife monitoring, habitat management, infrastructure (e.g., roads and bridges) and supervision of hunting/photo safaris (Kibonde, *pers. comm.*). Management will only occur when 95% of the wildlife and other resources are harvested legally and the off-take quantified. Currently, as all over Sub-Saharan Africa, maybe 5% or less of the off-take is legal and quantifiable. A questionnaire survey is underway (Kibonde, *pers. comm.*; Kibonde, 2005) to determine what traditional hunters and their communities want from the game

reserve and to see if there is a way to more positively integrate them into the formal management of the reserve so that the off-take of wildlife and other resources in the reserve can be monitored to assure sustainability. If this goal can be achieved, it will be irrelevant if the bushmeat and other resources are for auto-consumption or commercial trade. Ultimately, while anti-poaching may have helped game populations climb to what they are today in the Selous, in the long-term repression is not sustainable, while community involvement in a constructive way, along with education is the only hope for the Selous to maintain its structural and ecological integrity (Kibonde, 2005).

Ultimately, there is some concern that in reality the WMA process will remain complicated and the process stymied by bureaucracy as a means of the political technocratic elite retaining control over wildlife as a source of wealth linked to patronage and corruption (Jones & Murphree, 2004 *In: Child, B.*, 2004a).

9.6.3.7 Makuleke Contractual Park, South Africa

Contractual parks began in the 1980s with white landowners, enabling them to retain ownership while enabling the National Parks Board to expand areas under conservation. By the 1990s, the South African National Parks (SANparks) was experiencing land claims by rural communities relocated during the Apartheid period to expand parks and protected areas. Degazetting portions of a national park to a lower level of protection, thereby creating a “contractual park”, allowed multiple use of resources by communities, while being co-managed by SANparks and the local community. This is one mechanism by which SANparks has been able to maintain the integrity of its protected area system, while accommodating the needs of communities reclaiming their traditional territories. Contractual national parks are managed under a joint agreement between SANparks and the landowners, with most of the management delegated to SANparks, though such

responsibilities may be negotiated through a joint management board. In some (e.g., Richtersveld) but not all contractual parks (e.g., Makuleke), a ground rental is paid to the community (Reid & Turner, 2004 *In: Fabricius, et al.*, 2004).

The South African “Group Areas Act” resulted in the forced removal of seven villages belonging to the Makuleke in 1969 (DeGeorges, 1999a; Steenkamp & Uhr, 2000) and about 3,000 people (Mahoney & van Zyl, 2001). People were removed at gunpoint, homes burned and resettled on the border of the Kruger National Park (KNP), about 30 km southwest of the current contractual park (see Chapter 3, Section 3.6.2, Forced Removal, Kruger National Park, South Africa). This was done against the will of the people, many fleeing to Zimbabwe. There are strong kinship ties between the Makuleke community and two adjacent CAMPFIRE areas in Zimbabwe. The Makuleke are Shangaan, a hunting culture with strong ties to wildlife (DeGeorges, 1999a).

In 1994, under the new South African dispensation, the Makuleke community took the South African government to court to claim their land back. They are one of the first rural communities to have won their land claim and to have received restitution (DeGeorges, 1999a).

The current community consists of about 1,200 households with about 10,000 (DeGeorges, 1999a) to 15,000 beneficiaries (Mahoney & van Zyl, 2001). They currently live from subsistence farming and remittances from family working in urban centers and the mines (DeGeorges, 1999a).

The Makuleke community has a freehold title over the 25,000 ha contractual park, “Crooks Corner”, situated at the extreme northern part of the Kruger National Park. They can develop the land as long as the conservation status is unchanged. This area must stay in conservation for 99 years, while being leased to SANparks

for 50 years (Reid & Turner, 2004 *In: Fabricius, et al.*, 2004). They have formed a legal entity known as a communal property association (CPA), which can enter into joint venture with the private sector (DeGeorges, 1999a; Reid & Turner, 2004 *In: Fabricius, et al.*, 2004).

A joint management board has been formed made up of 50/50 representation from both the Kruger National Park and the CPA, who jointly develop an environmental management plan for the contractual park. This includes sustainable use of the natural resources such as hunting within the area of the contractual park (DeGeorges, 1999a; Reid & Turner, 2004 *In: Fabricius, et al.*, 2004). However, typical of Southern Africa where communal lands abut against state parks, Jones and Murphree (2004 *In: Child, B.*, 2004a) believe that co-management agreements in both the Makuleke and Richtersveld Contractual Parks are the result of unequal negotiation between a relatively disadvantaged community and a sophisticated and advantaged SANparks, which results in manipulated compliance and continued expropriation with limited community empowerment. For instance, to date, traditional hunting in the contractual park is prohibited by the Makuleke community members. Likewise, Colchester (2003) notes that in general most “joint management” schemes are “joint” in name only since local communities lack political power and financial resources, making them junior partners in decision-making.

All commercial rights are vested in the Makuleke CPA, but these activities must be compatible with the environmental management plan developed by the joint management committee (DeGeorges, 1999a; Reid & Turner, 2004 *In: Fabricius, et al.*, 2004). Over the first five years, SANparks will pay all environmental management costs. After five years, SANParks and the CPA will share the costs for environmental management of the contractual park, with costs to the CPA never to exceed 50% of their net profits. SANParks is willing to cover more costs

than the CPA as compensation for the state disallowing cattle and mining in the negotiated agreement (DeGeorges, 1999a).

Through a distance-learning program, 30 Makuleke youth are being trained in wildlife management. Slowly, over the next five to ten years, they will accept more responsibility for managing this area, with long-term technical backstopping from the Kruger National Park staff. An NGO, the Friends of Makuleke, also provides the community with advice and training (DeGeorges, 1999a). Additional concerns over the future of CBNRM in this area are discussed in Chapter 11, Section 11.11.5, Transfrontier Conservation Areas (TFCAs), Southern Africa.

9.6.3.8 CBNRM, subsistence fishery, Lake St Lucia, KwaZulu-Natal, South Africa

The following is extracted from Crook and Mann (2002). The 35,000 ha Lake St Lucia is the largest estuary on the eastern seaboard of Africa, situated in KwaZulu-Natal. It is part of the 250,000 ha Greater St. Lucia Wetland Park. It is an important nursery for marine fish and a World Heritage Site (Also, see Chapter 8, Section 8.14.1, Community Coastal Zone Management, Tanzania).

Relations between the local fishing community and the KwaZulu-Natal Nature Conservation Service (KNNCS), the old Natal Parks Board/NPB – in 2005 KwaZulu-Natal Wildlife, have been poor due to attempts by the provincial government agency to stop illegal netting. In 1992, there were about 72 illegal gill-netters operating, who relied on fishing for both food and income. They had an estimated 10 km of net, while annual yield/catch amounted to 91-135 tons/year. Although the authors call this fishery a “Common Property Resource”,

it was really an “Open Access Resource” that local government tried to manage, while cutting out the resource users, local fishermen.

The Oceanographic Research Institute (ORI) recommended a small legal subsistence gill net fishery, involving local people in the management of the fishery, which began in October 1994. Fishing committees were elected in three communities to represent fishermen in negotiations.

It was agreed that fishing would not take place around the river mouth that fish use as a refuge during high salinities. Based on the number of netters, the length of shoreline and estimated sustained yield, the number of allocated permits and total length of nets allowed was agreed on. Enumerators from the villages were trained to record catch data.

It was found that restrictions on the numbers of various species that could be caught/day was not enforceable since certain restricted species made up major components of the catches and the fish were dead by the time the gill nets were pulled.

The success at decentralizing control to local communities varied with community. In one village, Mduku, the *inkosi* (chief) was respected by the community. Only members with permits were allowed to net, monitoring was undertaken and violators were sanctioned (not allowed to fish). Fish were caught and sold within the community. They were unable to prevent fishermen from the neighboring community (Nibela) from fishing in their area.

At Nibela, there was no *inkosi*, the tribal authority was not respected, and some headmen (*izinduna*) and fishing committee members were believed to have a stake in illegal fishing. Illegal fishing on a large scale was a major problem.

The headman in charge of another community, Nkundusi, was supportive of legal fishing but was replaced. Unlike the other communities, the fishing committee charged fees for permits and fined people who broke the law; the money was supposedly used for the good of the fishery, but with no transparency. Illegal netting continued.

In addition to illegal netting at Nibela and Nkundusi, other common issues that lead to corruption and poor organization included:

- Fish, often undersized and restricted species, were often sold outside of the community;
- Illegal net fishing increased since the onset of the legal fishery despite the under-utilization of legal nets since fishing committee members claimed permits they did not use, but which cut off others from legally fishing;
- Even though the legal length of a net was 30 meters, the NPB removed nets from 50-900 meters, some with legal permit tags; and
- At Nibela and Nkundusi, fishing committees made up of once-off elected members that fishermen could not change, imposed rules that could not be modified by the fishermen, the possibility for change being essential if CBNRM is to work.

In all three areas, there was no re-election process for the fishing committees, so that accountability to members was non-existent. All committees asked for more permits, longer net limits and increased fishing areas, even though the permits were under-utilized. The KNNCS was required to enforce fishing area boundaries, something the communities were unable to accomplish.

The authors of this case study believed that the only way to get the communities self-organized was to threaten the communities with gradual withdrawal of netting rights by KNNCS. Those communities such as Mduku would not be penalized, while the other communities undertaking illegal fishing would be. An important first step is that communities must restrict access to the fishery and determine who within the community can fish, when and for how long. Monitoring will be necessary to assure the rules of the game are abided by. If the fishermen believe in the rules (e.g., are involved in determining the rules that are to their benefit), then they can undertake self-monitoring. For large areas, sub-organizations undertaking self-monitoring may be more effective. Peer pressure must be used to stop violators. For this to work there must be a respected community authority to control conflict, power struggles and agreed-on rules. If communities cannot be organized to manage the fishery resource as a “common property”, it will likely return to an “open access” resource.

Similar experiments are taking place in the Niger Delta of Mali moving from failed state centralized fisheries management that was in conflict with traditional localized management systems to more decentralized local management by stakeholders (Läe, Williams, Malam, Morand & Mikolasek, 2003).

9.6.3.9 Community fisheries management, Queen Elizabeth National Park, Uganda

In the past, the Queen Elizabeth National Park, Uganda, was known as having among the highest wildlife biomass in the world. In the late 1960s, the wildlife biomass was estimated at 29,490 kg/km². The only area that had a similar biomass was the contiguous *Parc National des Virunga* in the DRC with 20,470 kg/km². In comparison, the Serengeti National Park has no more than 6,300 kg/km². Historically, a few large species furnish the majority of biomass including hippo,

elephant, buffalo, Ugandan kob and topi. However, due to Uganda's 15-year civil war, their numbers were greatly reduced and they are currently recovering (Olivier, 1990 In: Ogwang & DeGeorges, 1992) (Table 9.5):

This dramatic decline in most species in the Queen Elizabeth National Park is indicative of what occurred across Uganda. There was less information available on other species found within the park including: the Ugandan defassa waterbuck (*Kobus defassa ugandae*), warthog (*Phacochoerus aethiopicus*), Nile bushbuck (*Tragelaphus scriptus bor*), Eastern bohor reedbuck (*Redunca redunca wardi*), giant forest hog (*Hylochoerus meinertzhageni*), bushpig (*Potamochoerus porcus*), sitatunga (*Tragelaphus spekei spekei*), four species of duiker, chimpanzee, red colobus, lion, leopard and spotted hyena. Published sightings existed of 545 species of birds, greater than any other park in world (Ogwang & DeGeorges, 1992).

Table 9.5: Changes in wildlife numbers of key species contributing to biomass, Queen Elizabeth National Park, 1969-1992

Species	Year 1969/70	1992	Percent Decline
Hippo, <i>Hippopotamus amphibius</i>	10,500	500	-95
Elephant, <i>Loxodonta africana knochenhaueri</i>	2,500	225	-91
Nile Buffalo, <i>Syncerus caffer aequinoctialis</i>	16,000	<5,000	-38
Topi, <i>Damaliscus lunatus jimela</i>	4,500	500	-89
Ugandan Kob, <i>Kobus kob thomasi</i>	10,000	17,500	+75
Extracted From: Olivier, 1990 In: Ogwang & DeGeorges, 1992			

Fishing Enclaves on Lakes George and Edward

When the Queen Elizabeth National Park was established in 1952, fishing villages were left as enclaves within the park on Lakes George and Edward. They were meant to be fishing camps of a temporary nature inhabited by men without their families. They have evolved into towns with schools, post offices, Resistance Committee/Council (RC)— local political units of government), etc. (Ogwang & DeGeorges, 1992). The park was created during a period when the area had been largely depopulated by the colonial government in the fight against sleeping sickness (Barrow, *et al.*, 2000).

In a 4,315 km² survey of the area of which the park constituted 54%, there were an estimated 79,000 houses, 17,000 cattle and 6,000 sheep and goats. Cattle density outside protected areas was 1.5 times the Uganda kob density: 13 cattle/km² versus 8 kob/km². In 1992, there were ten fishing village enclaves within the park with a total human population of 19,930 residents on park land. It is unclear, but a population of 9,421 appeared to be permanent residents, while the remainder appeared to be transients (e.g., family, traders, seasonal fishermen, etc.) who come and go (Ogwang & DeGeorges, 1992).

The annual fish catch of 5,000 metric tons for Lake George and 4,000 metric tons on Lake Edward was valued at US\$ 5.0 million. Fishermen were mostly hired labor from outside employed by boat owners who hold fishing rights (Ogwang & DeGeorges, 1992; Barrow, *et al.*, 2000). Only 10% of the village inhabitants were fishermen, while 60% of residents were women and children. It was estimated that 82% of the household heads were born outside the enclave villages, 59% had land outside the park (Infield, 1989 *In:* Barrow, *et al.*, 2000; Ogwang & DeGeorges, 1992) and 56% engaged in business services [e.g., importing matooke bananas (39% of imports) and other foodstuffs (29% of imports)] (Ogwang & DeGeorges, 1992).

Total annual wood consumption as fuelwood for charcoal and fish smoking was 6,883 m³ for park enclaves, much of which was from the park, and another 11,893 m³ from public enclaves and other villages close to the park. Other vegetative resources extracted from the park included building poles, papyrus (*Cyperus papyrus*) stems for thatch and fishnet floats cut from the ambatch tree (*Aeschynomene elaphroxylon*) (Ogwang & DeGeorges, 1992).

“Despite occasional attempts by the park management to remove villages from the park, and a general tension between the park authorities and the fishing communities, the industry has continued given its importance to the local economy. In recognition of this the park was declared a Biosphere Reserve in 1979, and the current management plan provides for zoning of the park into strict conservation areas, tourism areas, multiple use areas, and development areas. Community conservation initiatives in Queen Elizabeth National Park have developed largely in relation to the existence of the fishing villages. The peculiar nature of the villages has, however, made the development of community programs difficult. The villages have a small core of permanent residents, but a large number of transient workers or business people, attracted by the ready availability of cash” (Barrow, *et al.*, 2000).

In a meeting with RC3 chairmen, fishermen explained that Lake Edward is “their garden”. It was in their vested economic interests to protect their fishery resources. They were constantly fighting against illegal fishermen and the use of small mesh nets using self- and joint-patrolling with the Queen Elizabeth National Park staff. They requested that the Kampala net company stop supplying small mesh net to the community shops (Ogwang & DeGeorges, 1992).

They were also in the process of establishing "no-fishing nursery grounds", based on their knowledge of the biology and life history of the lake's fish. This was being undertaken in collaboration with the Fisheries Department (Ogwang & DeGeorges, 1992).

“Early initiatives included negotiated agreements with communities to allow access to firewood in the park, used for both domestic cooking and for fish smoking. Agreement was also reached to allow harvesting of papyrus for the roofing of village houses. More recently, a CARE project has been initiated to work with the fishing village communities on improving fishing methods, developing improved fish smoking kilns to reduce the quantities of fuel used, and establishing wood lots to supply the demand for fuel wood without recourse to the park’s wood resources” (Barrow, *et al.*, 2000).

One of the key hotel staff, who was also from the area, explained that to survive, local people needed resources located in the park and that cutting them off was only to ask for poaching and misuse of the resources. He felt strongly that controlled access and management of critical resources in multiple use areas of the park and its buffer zones was the best solution (Ogwang & DeGeorges, 1992).

“Conservation with the People” is clearly a stage too short.

It must be mentioned that 10,000 Basongora nomadic herders and their 40,000 cattle, chased out of the adjacent *Parc National des Virunga* in March 2006 and allowed to settle a 300 km² of the 5,100 km² Queen Elizabeth National Park, are threatening wildlife, especially lion, leopard and hyena that are being poisoned by the herders. Buffalo are showing signs of foot-and-mouth, a viral disease carried by cattle and pigs. This damage could take another 20 years to reverse (Ryu, 2007).

9.7 CBNRM SHORTCOMINGS, STAGE 3 CONSERVATION/WILDLIFE MANAGEMENT WITH THE PEOPLE

The anti-sustainable use movement (animal rights) and those who believe in state control and/or the decoupling of human needs in development projects from the harvest of large mammals have spoken out against the merits of CBNRM.

However, there has also been criticism from those who support the tenet of rural communities being integrally linked to the future of Africa's biodiversity, conservation and development that CBNRM initiatives and projects (Murphree, 2001 *In: Baldus, et al.*, 2001):

1. Make unwarranted assumptions about the existence and profiles of communities;
2. Encourage stratification and inequality within communities;
3. Are externally initiated and imposed;
4. Can be co-optive mechanisms for the indirect re-establishment of state or elite control;
5. Lack mechanisms for accountability and transparency, internally and externally resulting in corruption and nepotism at communal and higher levels;
6. Involve high transaction costs, especially time;
7. Require high facilitation input costs;
8. Require long start-up time frames;
9. Show little evidence that they encourage sustainable use or are sustainable themselves; and
10. Lack the technical and financial capacities for natural resource or institutional management.

Additional/similar shortcomings identified by Hitchcock (2000b) include:

1. Lack of sufficient technical assistance and training provided to members of the community;
2. Lack of sufficient information provided to the community about the options that they have;
3. Lack of sufficient emphasis on community participation in decision-making;

4. Unwillingness of higher-level institutions to devolve authority to communities to manage their own resources;
5. Economic benefits are captured by higher-level and middle-level institutions while local people receive relatively few direct benefits;
6. There often is inequity in the distribution of benefits at the community level along the lines of age, gender, class, and ethnicity;
7. While some jobs have been created such as community escort guides (CEGs), the numbers of these jobs tends to be low and the majority of the jobs tend to go to adult males and not to females or children; and
8. Local people tend to bear greater costs from increased biodiversity conservation efforts; for example, they tend to be arrested at higher rates than the general public for allegedly engaging in illegal activities such as hunting or collecting wild plants in conservation areas; they also tend to lose access to land and natural resources as a result of the establishment of protected areas.

Hitchcock (2000b) notes that most benefits go to common property benefits (e.g., roads, school, clinics, boreholes, etc.) that

“tend to mimic public goods...,” all members of the community benefit from them whether or not they engage actively in community-based conservation and development activities. Given these constraints, it is not surprising that local people often are reluctant to accept the structure of incentives offered by these new programs”.

An International Institute for Environment and Development (IIED) analysis (Fabricius, *et al.*, 2001) came up with shortcomings similar to the above plus:

- Widely diverging goals among stakeholders (e.g., government, private sector and community) often resulting in conflicts over resource use and human impacts on biodiversity;
- Intra-community competition for access to resources and benefits, sub-units within the community with different goals and aspirations;
- Communication gap between scientists/researchers who hold formal knowledge and local communities/resource users with informal knowledge, especially over what level of resource use is sustainable;²⁵⁵
- Community rarely makes the linkage between benefits and sustainable wildlife/resource management;
- Question of whether donor funds would be best used to build institutions as opposed to helping individual entrepreneurs; and
- Household benefits tend to be very low, though more important may be political empowerment, biodiversity conservation and increased cultural awareness.

Benson and Darracq (2001), viewing the world as a multi-dimensional set of parameters, came up with similar constraints, which must be addressed at an individual, group and societal level to illicit attitudinal changes towards the environment in becoming natural resource stewards. These same parameters must also be addressed if CBNRM, as an applied concept is to prove sustainable. This includes (Benson & Darracq, 2001):

1. The earth's physical and biological systems;
2. Economics (money and trade) regulating the exchange of goods and services;

²⁵⁵ Note: The authors' experience is that very often scientists and researchers are not trained in adaptive management – that is determining sustainable off-take quotas and thus take the precautionary principle noted in Section 9.2.1, Precautionary Principle; Studying Wildlife to Extinction – that is assume that the resources must be protected rather than utilized.

3. One's personal psychology, personality, wants, needs and investment in the issue;
4. The norms of the group, society and cultures that enable or restrict the actions of individuals and the group as a whole;
5. Power structures through laws and political systems that protect or suppress the rights of individuals and society; and
6. Implementation opportunities or barriers where appropriate technologies, skills and administrative authorities to perform desired tasks are encouraged, discouraged or nonexistent.

Most CBNRM Stage 3 programs tend to be too narrowly focused, the majority of CBNRM programs focusing on “economics” and “legal/enforcement” while failing to address individual and societal norms and their ties to wildlife, land and other resources. Many collect no biological or physical data as a means of monitoring sustainability.

The above concerns and others are discussed below in some detail.

9.7.1 Socially Constructed Stalemates

This term applies to situations in which interest groups working in parallel block the achievement of the objectives of each other. An example would be a situation in which a conservation agency attempts to conserve wildlife in a protected area and to generate revenue through tourism by leasing concessions to tour operators. Meanwhile, the principal economic opportunity of adjacent communities is traditional hunting (currently illegal). The conservation agency tries but is unable to effectively enforce the law. The tour operators are unwilling to contribute to the local economy and the communities have no option but to continue hunting (illegally), turning wildlife into an unmanageable open access resource, which

reduces the conservation status of the wildlife and reduces the value of the tourist assets. This is a socially constructed stalemate, a lose-lose situation. It results from the capacity of each party being sufficiently balanced to allow each to veto the agenda of the others and/or to accept the needs of others and their integration into the formal management of the area. It is important to realize that rural communities, while holding very limited formal authority or capacity, hold major powers of veto over the formal sector because of their overwhelming numbers on the ground and local knowledge (Bell, 1999).

The way to escape the stalemate is for each party to compromise sufficiently to give the other enough of what its members want in order for them to withdraw their veto (Bell, 1999). This rarely happens when decisions come from the top and are sent to the bottom, government game departments, safari and tourism operators imposing restrictions on communities with little or no dialogue.

9.7.2 Reluctance to Devolve Control and Ownership of Resources to Landholders

Murphree's (Marshall) Law states that

“all societies are stratified. Each stratum strives to wrest control of decisions and money from levels above and resists devolution of control to levels below”.

The operation of Murphree's Law results in the characteristic “aborted devolution of authority” as the commonest constraint to the successful implementation of CBNRM. Typically, Murphree's Law can be seen in the unwillingness of government authorities to devolve control of resource management to the community level. The operation of Murphree's Law may be seen as the effect of

human nature operating in a vertical sense, between levels of society (Bell, 1999; Duffy, 2000). Child, B (2004a) argues that in fact

“devolved conservation is a direct antidote to the elite capture of the past, with the massive challenge of transferring control from a few techno-bureaucrats to hundreds of thousands of ordinary people”

which at the core are full and clear rights to benefit, manage and allocate resources.

“Power structures at the political and economic center are not disposed to surrender their privileges, and will use their power, including their ability to shape policy and law, to maintain the monopolies of their position...The reason lies fundamentally in the value of natural resources and the importance of power to control and benefit from them. The history of colonial Africa is a history of the appropriation of this power and benefit by the state from those who live with and use natural resources; rural communities. This was accomplished by the state declaring ownership over natural resources and in turn conferring weak user rights to the land on which communities live. Without exception, this condition has persisted into modern post-colonial Africa. Thus communal lands continue to be in various degrees of fiefdoms of state bureaucracies, political elite and their private sector partners”
(Murphree, 2001 *In:* Baldus, *et al.*, 2001).

Speaking of the LIRD program as it relates to devolution, Child and Clayton (2002) state that

“often mis-managed community programs are actually manipulated to dis-empower rural people (Ribot, 2001 *In:* Child & Clayton, 2002). This leads us to conclude that only fiscal devolution to a scale that allows face-to-face decision-making and accountability, and that operate through institutions that are carefully designed to incorporate the principles of democracy, transparency, equity, and accountability to a constituency, will be ultimately successful. Consequently, we are optimistic about the

ability of communities to integrate local resource management. However, we are also pessimistic about whether the state hegemony will encourage, or even permit, this to happen”.

Speaking of forestry, but equally applying to wildlife, Messer (2001) also believes that IMF/World Bank structural adjustment policies (SAPs) have been counterproductive to full devolution since cash strapped governments in Sub-Saharan Africa hang on to the resource as a major source of income.

“In Africa – including Sub-Saharan Africa and North Africa – perhaps more than elsewhere, decentralization programs have been much influenced by donor conditionalities and the downsizing of central bureaucracies due to financial constraints. This phenomenon is, paradoxically, both a factor driving decentralization, and also an obstacle thereto. The high indebtedness of national governments often forces them to sell to foreign companies logging rights, mining concessions, estate crops, etc., within large tracts of rural areas, a source of revenue that would diminish considerably if full decision-making power over those rural areas were devolved to the populations living on them” (see Chapter 12, Section 12.3.4.1, Downsizing governments).

Decentralization (e.g., co-management or collaborative negotiated management) is the delegation of responsibility and limited authority to subordinate or dispersed units of hierarchical jurisdiction, which have primary accountability upwards to their superiors in the hierarchy (Murphree, 2001 *In:* Baldus, *et al.*, 2001). Unfortunately, this process which should lead to “devolution” is fraught with many obstacles, mostly linked to “Murphree’s Law”, in which the economic strata above is reluctant to devolve authority and thus economic gain to the next lower level of society. Messer (2001) in describing decentralization as it applies to community management of natural forests states that

“ultimately, decentralization involves an epistemology²⁵⁶ clash of different conceptions of forests and NRM (Natural Resource Management) between the rural dwellers using them on a daily basis and the mostly urban-educated individuals staffing ministries”.

Most CBNRM programs (CAMPFIRE, ADMADE, SCP, Botswana Trusts, LIFE, Cullman Hurt) are stuck in this mode where communities lack true empowerment and ownership over their wildlife. For instance in Namibia, the 1996 Wildlife Conservation Amendment is enabling to communities, while Ministry of Environment and Tourism regulations are restrictive and prescriptive, not allowing communities the autonomy to define who can be conservancy members/beneficiaries. Rights are limited, communities being able to make few crucial management decisions without permission from government (Long, 2004)

Devolution involves the creation of relative autonomous realms of authority, responsibility and entitlement with a primary accountability to their own constituencies. In essence, this is what exists on private white-owned game ranches in Namibia, South Africa, Botswana, Zambia and at one time Zimbabwe (prior to the radical land reform policies of 2000). Devolution of such authority to communal areas faces strong and entrenched opposition by the state, its bureaucracies and the private sector.

The state is loath to legitimize local jurisdictions in ways that diminish its ability to claim the benefits from these resources. The “wildlife pie” is only so big and governments are reluctant to see their share diminished. This can be linked to the patronage politics and corruption endemic to much of Sub-Saharan Africa, with the distribution of wealth from wildlife to the elite, their cronies and extended families being no different than what commonly happens with mineral and

²⁵⁶ Study or a theory of the nature and grounds of knowledge especially with reference to its limits and validity (Webster, 1967).

petroleum resources, timber, etc. across the subcontinent (see Chapter 11, Section 11.6.3, Neo-Patrimonial Clientelism, the Big Man and “Cosmetic Democracy”). Even when the state grasps the importance of local management and stewardship, it prefers decentralization (local government control as opposed to central control) over devolution. Thus, central government is relieved of having to provide administrative and development subsidies to local government, as in Tanzania and Zimbabwe’s programs to date. The political class seems to have no power in transforming the autocratic postcolonial state, with devolution of land and resource tenure being inextricably linked to democratization (Jones & Murphree, 2004 *In: Child, B.*, 2004a).

Boone (2003) presents a political model (see Chapter 3, Figure 3.1): Determinants of institutional arrangements between rural societies and colonial/post-colonial governments, in which the willingness of government to devolve control over resources depends on the value of the resource and the strength of the rural elite to bring their constituencies into the modern political arena to support the elite running the modern states left after colonialism:

- **Power sharing** when there is a valuable resource and the rural elite are politically powerful – indirect rule/devolution, but devolution often meaning that a local rural elite along with central government are the beneficiaries, not the rural masses;
- **Usurpation** when there is a valuable resource and the rural elite may be politically powerful but are not dependent on or offer anything by central government cooperating - direct rule, centralized authority often using government bureaucracies, parastatals and even military/police forces;
- **Administrative occupation** when there is not a strong rural hierarchy that can be used to control the rural populace – direct rule/decentralization with local government officials managing the people and the resources,

mostly to the advantage of the state but with little input or support from the state; and

- **Non-incorporation**, indirect rule or devolved authority in areas where there are no valuable resources (e.g., nomadic areas of the Sahel).

Boone's (2003) model was undertaken primarily in analyzing farming in West Africa and decisions by central government regarding approaches to governance, which are based on existing social structures and on central government's ability to access wealth generated from the resource base.

This model can readily apply to other resources. Certainly, as is seen with case studies in this and other chapters, full devolution is far from being achieved, with a small percentage, if any, of the profits reaching the rural people. In most cases, one observes what appears to be a form of usurpation in which bureaucracies and middlemen (safari, tour operators, logging, mining companies and NGOs) are placed in rural areas to extract the wealth, both directly and indirectly, while the majority live in poverty and are often repressed by these middlemen. This is certainly true for the wildlife covered in some detail in this chapter and for fisheries, especially the Nile perch as discussed in Chapter 4 and the kapenta discussed in Chapter 7 on dams (see Chapter 7, Section 7.8.5.3, Kariba Dam, Zimbabwe, Zambezi River; Section 7.8.5.4, Cahora Bassa Reservoir, Mozambique). Commercial logging as discussed in Chapter 11 in Cameroon (Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon (Division of Boumba-et-Ngoko), the Forest People and the *Dobi Dobi*, More Parks and Protected Areas) and Congo Brazzaville (Chapter 11, Section 11.11.7, Case Study Bongo in the Congo [Brazzaville]) is another example of usurpation. In the extreme, the Selous program might be considered a form of usurpation in which paramilitary forces, costing upwards of US\$ 750,000/year of a US\$ 2 million annual budget (see Section 9.5.7, Selous Conservation Program [SCP], Tanzania

& Section 9.6.3.6, SCP, Tanzania), are used to repress the local inhabitants as a means of keeping them from accessing natural resources in the reserve, while middlemen – safari operators – extract wealth for themselves and the bureaucratic elite in the name of conservation. The case studies on the Comoé-Leraba Game Reserve in Burkina Faso (see Section 9.8.9, *Gestion des Terroirs*, West Africa), the Mpembeni Community Conservation Game Reserve in South Africa (see Section 9.8.11, Emerging Community Devolution Model - Public/Private/Community Partnerships (PPCPs) - Mpembeni Community Conservation Game Reserve – Hluhluwe Game Reserve - South Africa), the artisanal fishery of the St. Lucia Estuary (see Section 9.6.3.8, CBNRM, subsistence fishery, Lake St Lucia, KwaZulu-Natal, South Africa), the IIngwesi Group Ranch in Kenya (see Section 9.8.7, IIngwesi Lodge, Mukogodo Pilot Tourist Program, Kenya) and the newer CBNRM models such as the Botswana Trust Model and LIFE in Namibia are moving towards power sharing with local communities. In some cases, the pressure does not come from within but from international donor agencies and NGOs, which puts into question whether imposed solutions are sustainable once these external forces are removed as noted in the Botswana Trust Model where once USAID funding ended, so did government enthusiasm. Programs such as the Rwenzori Mountaineering Services (RMS) of Uganda (see Chapter 11, Section 11.11.3, Rwenzori Mountains National Park - a success story of rural people managing a natural area, and then foreign aid and NGOs arrived) and the Makuleke community of South Africa (see Section 9.6.3.7, Makuleke Contractual Park, South Africa) resulted from a change in governments with new and dynamic leadership that wished to empower local people and likely to some degree well organized rural communities (Bakonjo in the Rwenzoris) or support from outside NGOs (e.g., Friends of the Makuleke) that enabled these communities to negotiate power sharing relationships economically and to some degree in management.

Contreras (2000 *In:* Messer, 2001) sums up obstacles to effective devolution in Sub-Saharan Africa:

- “The lack of financial resources at local level whether they are transferred from the centre or mobilized locally;”
- “The general structural weakness of African forestry institutions” (also wildlife, fisheries and park institutions);
- “Policies and legislative bodies continue to be based on weak centralized institutions inherited from the colonial period;”
- The tension between weak-modern-urban versus strong-traditional-rural systems of governance;
- “The reluctance of central bureaucrats to transfer responsibilities downward for fear of losing prestige and job security;”
- “The resistance to establish legal pluralism, that is to say enforcement and regulation powers at the decentralized levels;” and
- “The legal texts do not clarify the powers and responsibilities of decentralized institutions and local communities and the rules that would govern their relations”.

This tendency (state preferring decentralization over devolution) is the primary reason for the failure of programs to create local natural resource management jurisdictions. Responsibility is divorced from authority and entitlement, these programs remaining co-optive rather than empowering (Murphree, 1998a; Murphree, 2001; Baker, 2002). This is institutionally fatal, since when authority and responsibility are separated, institutions rarely perform effectively (Murphree, 1998a). As a result, commonly, “community-based” resource management initiatives turn out to be efforts to co-opt or bribe local peoples while authority remains firmly held in state hands (Murphree, 1998a).

Thus, in cases like CAMPFIRE, Tanzania's WMAs and the Botswana Trusts, the top-down preferences of central government have merely been replaced to a large degree by the top-down preferences of local government and/or the central government still retains much of the decision-making authority and economic benefits. Thus, people participate in projects, but the state retains a large measure of direction and control. Local government often resists accountability and becomes a de facto local agent of central government (Katerere & Chikoku, 2002 *In: WSP*, 2002). In Zimbabwe's communal areas, Hasler (1999) concludes that

“in fact all of the current and previous scrutiny points to one major analytical critique: that the CAMPFIRE movement needs to rigorously accept the ultimate goal purpose and spirit of the fledgling project: the devolution of legal rights and management functions to local (village) level in order to foster the sustainable management of wildlife by people affected by wildlife”.

Another reason devolution often fails is that NGOs wish to control CBNRM programs, making themselves indispensable middlemen, as a means of obtaining donor moneys on which they survive (Katerere & Chikoku, 2002 *In: WSP*, 2002). This is often a hindrance to local communities going through the process of making their own decisions, learning from their mistakes and in the process becoming independent in decision-making.

Decentralization falls short of the combination of authority, responsibility and entitlement required for CBNRM or “Conservation by the People”. Thus for CBNRM or “Conservation by the People” to work, a strong devolutionist approach is needed in which the locus of initiative and decision-making is shifted from the state to relatively autonomous localized jurisdictions. The role of the state changes from being directive and inhibitive to facilitative through providing coordination, extension, infrastructure and arbitration. Enforcement is a last resort, which should come from the local community to protect its natural

resources from outsiders or its own members who fail to abide by established community laws.

For CBNRM to work, there will have to be significant transfers of power, rights, resources and the right to directly benefit from the sustainable management of these resources. There will be winners (community) and losers (government and private sector). Until devolution is the official policy, CBNRM, conservation and development will deal with the symptoms rather than the causes for the failures to date (Murphree, 2001 *In:* Baldus, *et al.*, 2001). Hulme and Taylor (2000 *In:* Lee & Kirkpatrick, 2000) back this up by concluding that wildlife utilization as a long-term sustainable land use option can be considered unlikely unless 1) appropriate authority is devolved from the district (local government) to the ward (local villages) level and 2) community wildlife producers participate in the decision-making framework, involving local communities as active participants instead of passive recipients in natural resource management (e.g., becoming involved in wildlife monitoring, quota setting, anti-poaching, community run hunting and tourism companies and selection of joint venture partners).

9.7.2.1 Devolution through policy reform, land and resource tenure

“Historically control over land...has always been vital to the livelihoods of the world’s poorest people. Lack of access to land not only denies people the ability to gather their own foods: it also excludes them from a source of power. Who controls this land – and how they do so – affects how land is used and to whom the benefits accrue” (Suliman, 1999 *In:* Koch, 2004 *In:* Fabricius, *et al.*, 2004).

“Unless property rights (land tenure) of long-term residential peoples are respected and economic benefits from the creation of protected areas accrue in part directly to the communities living in and near them, it is unlikely that nature reserves will endure. Local communities must also be involved in the planning and boundary

marking of reserves. Most important, their traditions must be respected” (Kemf, 1993 *In: Colchester*, 1994).

“Consequently, while what is wild cannot in the strict sense be owned, giving the right to use it to those who hold title to the land where it occurs creates a sense of ownership in the wider sense. Where the connection between land tenure and user rights has this result, trade is least likely to produce declines. The owners of the land feel they own its wildlife and it is no longer free for anyone to take. Where user rights have not been married to land tenure, conservation has seldom worked” (Parker, 2004).

Junge (2004) states that the lack of ownership or tenure over land and resources and their corresponding benefits is a major reason why so many development initiatives have failed over the past decades. Without secure rights of access to natural resources, rural people will not have a long-term interest in managing them or participating in CBNRM. Tenure also can be regarded as the extent to which an individual or community has rights of access to a resource and the degree of those rights (IUCN/SASUSG, 1997).

“Secure tenure over, or clear use rights to, land and natural resources is of crucial importance if rural people are to manage their resources (Barrow, 1990; 1996 all *In: Barrow, et al.*, 2000). Land reforms aimed at securing these rights and obligations are essential for improving natural resource management” (Barrow, *et al.*, 2000).

Watkin (2003) advocates that tenure must address all resources and not just land. Barrow, *et al.* (2000) provide the following information (Table 9.6) summarizing tenurial systems [see Chapter 5, Section, 5.6.1, Colonialism and its Impact on Land/Soil Degradation and Agriculture in Sub-Saharan Africa (SSA)].

Table 9.6: Links between different tenurial arrangements and potential for community conservation		
Tenure: State	Tenure: <i>de facto</i> people	Tenure: <i>de jure</i> people
National park, game Reserve, Forest Reserve	Customary, trust, mailo (in Uganda)	Titled group or individual, company, freehold/lease
Conservation main objective either national or global, rarely local	Conservation seen as component of rural livelihoods & rural economics – often negative	
Protected Area Outreach	Collaborative management arrangement	Community-based conservation
Revenue & benefit sharing, conflict resolution, Problem Animal Control (PAC)	Agreement on resource use by type, amount, whom & over what time frame; conflict resolution, problem animal management	Conservation as part of land use – may be a major component – & so more likely to be used sustainably; or may be minor, & unless critical to people, will probably not last. Basis on cultural & economic benefits which accrue
Wildlife part of ‘controlled, ‘pristine’ landscapes. Control vested in state		Wildlife as part of ‘managed’ landscape. If wildlife is not a significant economic component, it will probably tend to disappear, and be substituted by ‘more economic forms’ of land use. If wildlife is a significant economic component to users, then population pressures, & issues of inclusion & exclusion will be important so that wildlife can continue to be economically important

Source: Barrow, *et al.* (2000). Reproduced with permission, IIED, www.iied.org.

Barrow, *et al.* (2000) explain the following.

“Today, two sets of contrasting tenure rules co-exist in the region: statutory and customary. Conflict arises because in statutory law land is treated as a single unitary resource, while in customary law it is not. Customary law distinguishes in detail between resources and is a complex bundle of rights of access, of renewable or consumptive use, and of disposal. Such rights may be disaggregated by resource; or certain wildlife may be used under certain conditions and at certain times by defined groups of users; or individual trees or groups of trees may be subject to different rights by product and by time, for instance when to grow or browse (Barrow, 1996 In: Barrow, *et al.*, 2000). While communal tenure is complex, it has two essential elements: equal access to land, and the legal and economic fact that land is not a commodity (Okoth-Ogendo, 1988 In: Barrow, *et al.*, 2000). Government policy tends to promote privatization of land, since land suitable for cultivation is

thought to be under-utilized if left to, for example, pastoralism. This misconception has allowed private individuals, parastatals and government bodies to take over such land. Confusion over the relative status of customary and statutory laws relating to land and resource tenure has led a number of African states to revise land laws. At least 9 Sub-Saharan countries, including Uganda and Tanzania, are in this process, and many of the issues are similar, including the:

- Role of the state in land ownership and control,
- Future of traditional forms of land ownership,
- Extent to which land regulation should be democratized, and
- The Extent to which a market in land may be encouraged without unrecoverable social cost" (*Wily, 1997 In: Barrow, et al., 2000*).

"...Land tenure cannot be separated from land use. Tenure rules emphasize human issues and regulation of competing interests in land use. Land use emphasizes human and environmental issues, and the regulation of its use to conform with acceptable methods of husbandry and conservation. Thus the holder of tenurial rights has to assume that the objectives of land use are realized. Therefore, land use decision-making is a tenure issue" (*Okoth-Owiro, 1988 In: Barrow, et al., 2000*) (*Barrow, et al., 2000*).

In the principal author's experience, true customary tenure exists only in very isolated areas of Sub-Saharan Africa where local societies have little or no contact with governments, something that is becoming increasingly rare. Often customary tenurial land and resource rights are suppressed and/or in conflict with statutory rights. Statutory land tenure appears in the following forms (*Barrow & Murphree, 1998*), which the authors believe must eventually move towards communal ownership if these natural systems are to survive:

- **State ownership.** Protected areas in Africa were usually established without the participation or consent of local people and many times involved their forced removal. Traditional tenure was replaced with "Western" state ownership. This exclusive ownership led to no community

or resource user involvement or benefit flows except through “theft” of government assets. Protected area outreach attempts to introduce the idea of broadening the tenure arrangement, therefore assuming some level of tenure rights for local communities, converted into benefits, while government retains “legal” ownership. Conservation is the primary objective while rural livelihoods are of secondary importance. Dialogue, conflict resolution and forms of benefit sharing arrangements (e.g., percentage of gate fees to community), which do not include use of protected area natural resources, are the major components of outreach. In essence, CBNRM comes under this category.

- **Collaborative or co-management management agreements.** Collaborative management represents an arrangement whereby a community or a group of resource users and a conservation authority collaborate to jointly manage a resource, certain resources or an area of conservation value. The collaborative arrangement may also be between a private sector interest and a community or a conservation authority. The resource(s) or conservation area is usually governed by national policy and legal instruments and not legally owned by individuals or local resource users, for example national parks, game reserves, certain tree species. Use will contribute directly to rural poverty alleviation, but will normally be confined to those who live relatively close to the protected area. *Gestion des Terroirs* (see Section 9.8.9, *Gestion des Terroirs*, West Africa), described below might be considered a good example of this.
- **Ownership of land and its resources.** The basis for conservation and natural resource management lies with the community or resource users. The "community" has ownership of their resources. In terms of the balance between rural people and government, government retains some rights, but normally only one of last resort. In Kenya, group cooperatives and private ranches are halfway there. They own their own land, which is

unique for Sub-Saharan Africa, but they are still fighting to take back ownership of wildlife from the state (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya and Chapter 11, Section 11.11.9, Kenya Wildlife Service (KWS) – Living on donor handouts, negative impact on Kenya's wildlife outside parks).

These areas are very cloudy. The only place in Africa where full government recognized devolution over land and wildlife exists is on private white-owned game ranches in South Africa, Namibia and Botswana. Bond, *et al.* (2004 *In: Child, B.* 2004a) believe that

“a critical limitation of early Zimbabwean resettlement models (since 2000), which mitigated against land and natural resources management as well as settler investment, was a lack of proprietorship over land and natural resources: the tenurial conditions that allowed the deterioration of communal land were simply transferred to the newly acquired private land...A necessary...condition for successful wildlife-based resettlement is that levels of proprietorship equal to or greater than currently enjoyed by commercial farmers are granted to the new owners of the land”.

Whether out of anger, seeing wildlife as a white person's prerogative or out of ignorance, many of Zimbabwe's game ranches have been devastated, with from 60-80% of the game being eliminated on these resettled farms/ranches. Zimbabwe, the initiator of private game ranches, has taken a reverse step with its radical land reform beginning in 2000 whereby many game ranches have been invaded or confiscated (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife).

Likewise, Jones (1999b) states that in Namibia (9.6.3.5 LIFE, Namibia, Nyae Nyae Conservancy)

“the conservancy approach provides communities with resource rights but not land rights. While a specified group of people gain exclusive access to the use of and benefit from wildlife and tourism on their land, they have no right of exclusion from the land itself. In many parts of Namibia a de facto open access system to land prevails - only where traditional authorities are particularly strong and government is willing to back their land allocations, is a system of exclusion possible. This has meant constraints for conservancies developing wildlife and tourism as land use options. While conservancy members might abide by conservancy land use and management plans, there is little to stop outsiders from moving livestock on to conservancy land”.

“Currently, due to the new Government's politics, ‘One Namibia One Nation,’ there is tremendous political pressure to move people from the more populated and thus environmentally degraded communal areas, as well as, Herero refugees from Botswana (Approximately 4,000 Herero refugees with 50,000 head of cattle) without considering the landuse potential/economics, and the human/livestock carrying capacity of Bushmanland” (USAID, 1992).

In 2005, while having formed conservancies and having wildlife user rights, the San are fighting court battles to prevent the invasion by Hereros who wish the land for livestock, which will certainly negatively impact wildlife (Arnold, *pers comm.*).

Rural communities in Kenya, on the other hand, have ownership over their lands but not their resources, with dire consequences for wildlife as they opt for other land uses that can provide them with income (see Chapter 5, Section 5.7.1.3 Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya and Chapter 11, Section 11.11.9 Kenya Wildlife Service (KWS) – Living on Donor Handouts, Negative Impact on Kenya's Wildlife Outside Parks).

In Sub-Saharan Africa, at the beginning of the 21st century, in most countries, critical wildlife areas and the wildlife itself is still owned by the state. In fact, communal resources throughout the region are centrally controlled by the state as

discussed (see Chapter 3). Land was rapidly centralized by the state at independence with usufruct²⁵⁷ rights to rural communities that clash with traditional common property ownership where powers are vested in traditional leaders for control and access to this land (Jones & Murphree, 2004 *In Child, B.*, 2004a).

Ultimately, Emerton and Mfundu (1999) argue that for wildlife to survive, government policies must favor wildlife over agriculture as a land use, including ownership over wildlife and the right to directly benefit from its use and other resources found within the confines of its habitat, as well as in secure land tenure.

“Tenure is a critical factor for conservation, since it determines the linkages between responsibility and authority over land and natural resources, and also determines the incentive structures for sustainable use” (Murphree, 1996, *In: Barrow, et al.*, 2000).

Access to land facilitates greater access to other resources thereby providing opportunities to rural communities to improve their standard of living. In Southern Africa, issues exist over white-owned commercial land and the former owners comprised of rural African communities (see Chapter 5, Section 5.7.4, Land Reform/Redistribution without Integrating Local Communities as a Constraint to Agricultural Production; Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife; Section 5.7.4.2, Land reform and South Africa; Section 5.7.4.3, Land reform around the corner in Namibia and Section 5.7.4.4, Land reform and civil war in the Ivory Coast). Unless this land issue and its tenure can be resolved, the feasibility of CBNRM comes into question (Katerere & Chikoku, 2002 *In: WSP*, 2002). According to IUCN/SASUSG (1997), tenure enhances sustainability of CBNRM and of natural resources when:

- Rights of access are clearly defined and accepted;

²⁵⁷ Right to use but owned by someone else

- The ability to enforce those rights exists; and
- The unit of management and accountability is small and functionally efficient.

Similar to private game ranches in Southern Africa, the success of CBNRM initiatives may largely depend on legal ownership over wildlife (Katerere & Chikoku, 2002 *In:* WSP, 2002), timber, mineral and other resources where community structures obtain the majority of the benefits from partnering with the West to use their extractive technologies, while, like any entrepreneur, paying taxes to the government. It is argued that individual tenure versus communal tenure risks to see land subdivided into units that cannot support wildlife ecologically or economically. The communities should own not only the land but also the game, as on private farms in Southern Africa, as long as it is not abused. Junge (2004) concludes that resource tenure rights do not need to be private to be secure, though the authors argue that “private” can be communal instead of individual (e.g., community member shareholder run companies). Tenure rights based on membership in culturally based local groups are often more secure than those based on freehold tenure or leasehold introduced and backed by the state.

“In areas where the elders’ authority has been reduced, customary management rules are increasingly difficult to enforce (Scherr, 1989 *In:* Barrow, *et al.*, 2000). Where some authority remains, such rules can have a significant beneficial role in development and should be fostered and built upon” (Barrow, *et al.*, 2000).

Regardless, minimum economically & ecologically viable sizes of natural areas, ranches and farms, beyond which subdivision can no longer occur, must be determined and enforced – in collaboration with the owner(s) - based upon soils, rainfall, vegetation, and needs of wildlife (see Section 5.7.1, Property Rights and Land Tenure, Constraints to Soil Fertility and Agricultural Production).

A problem becomes – what is economically viable and for whom (e.g., a rich Pretoria lawyer with excess capital who is not interested in the economics, other than a tax write-off, versus a game rancher or community who must live from the resources on their land)? In many cases, as will be discussed, the resource/human population ratio around communal areas is so low that at the household level pure economics will likely not be the determining factor alone in deciding if a community will retain an area for wildlife and other natural resources. Less tangible aspects such as cultural, religious and ancestral ties to wildlife and other resources, and a feeling of ownership, may be as, if not more important in the final decision as to a chosen land use and the value of maintaining the spatial integrity of an area.

It is also not clear that in much of Sub-Saharan Africa the subdivision of land through privatization and its subsequent fragmentation is the best solution in savanna areas where wildlife and livestock may be the best land use. Fragmentation can result in the loss of complete ecosystems necessary to sustain wildlife and/or traditional lifestyles (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya). Thus, maintaining communal ownership in such cases may be the best way of assuring that land remains as both an economic and ecological unit.

“The extensive tracts of land required to support wild animal populations are being physically demarcated and split into agricultural units which threaten wildlife, for example around the Nairobi National Park dispersal area, the Maasai Mara National Reserve (Norton-Griffiths, 1996 *In:* Barrow, *et al.*, 2000), and the Amboseli-Tsavo region in Kenya (Southgate & Hulme, 1996 *In:* Barrow, *et al.*, 2000). Many land units are now smaller than the minimum viable area for wildlife populations (Howard, 1995; Mwau, 1996 both *In:* Barrow, *et al.*, 2000). In terms of communal rights to natural resources, it is important to understand the heterogeneity of a community, the different actors that make up that community based on class, religion, gender, origin, socio-

economic status, etc. This diversity, combined with the multiple and often mutually exclusive use that can be made of natural resources, complicates the equitable distribution of rights of access in terms of who, when, how much, and what? (Fortmann, 1987 *In:* Barrow, *et al.*, 2000) However, community control over natural resources, both directly and indirectly, has a number of advantages, including that:

- Natural resources can be managed as a whole and the use can be spread over a wider area;
- Natural products can be distributed more equitably across the community.
- The community can use the area as an asset to meet its needs;
- The community may be better able to protect the natural resources against incursions from outside (Fortmann, 1987 *In:* Barrow, *et al.*, 2000); and
- Within a communal access system, there may be mixed and varied individual rights to natural resources, which can be better regulated by the community than by government” (Barrow, 1996).

On the other hand, chopping up formerly white-owned ranches, often marginal for agriculture, into small subsistence plots will only solve land hunger for one generation. Then the rural community will be back to square one, facing degraded land, poverty and more land hunger. It is doubtful for a number of reasons based on the experiences of economies of scale that rural economies based on subsistence agriculture will be able to produce enough food to feed the increasingly urban centers (see Chapter 5, Section 5.7.5, Food Security and Urbanization in Sub-Saharan Africa). Reallocated ranches located in environments unsuitable/marginal for agriculture need to be managed as economic and ecological units for wildlife and/or livestock as are communally managed cooperative ranches in Kenya. As George Pangeti of the Zimbabwe Parks Board explains (*pers. comm.*), the issue of land reform in Zimbabwe was passé in 2004. Today the issue is appropriate land use. Bond, *et al.* (2004 *In:* Child, B. 2004a) believe that where land redistribution and resettlement occurs, be it in Zimbabwe or elsewhere in Sub-Saharan Africa, where wildlife is the best

land use, one of the biggest challenges will be to avoid land fragmentation resulting in unviable land sizes to economically and/or ecologically support wildlife. In much of Africa, the best land use is wildlife, which can be considered a form of agriculture/”game” ranching/farming – something that many Western donors and NGOs have a difficult time dealing with and accepting. As discussed in Chapter 5, trying to turn this marginal land into a breadbasket is a pipe dream and can result in serious habitat and soil degradation in many savanna areas that comprise 70-75% of Sub-Saharan Africa, where fallow agriculture is disappearing. Wildlife must be recognized internationally as a major land use in Sub-Saharan Africa and rural Africans must be helped in managing this land use to meet their needs.

Conflict between state and customary tenurial rights poses one of the biggest challenges in determining ultimate land use. In fact, as has and will be shown in numerous case studies, keeping land/resources under state ownership is often a recipe for communities opting out of wildlife as a land use. State tenurial rights are written down, while customary rights are oral and handed down from one generation to the next. Tenurial issues involve not only land, but also who has legal access to various resources, when and how (e.g., wildlife, grazing rights, fishing rights, right to collect thatch, honey, firewood, etc.) within a given geographical area. Ultimately, land and resource ownership determines use, who benefits and who has rights and responsibilities for that land and its resources (Barrow & Murphree, 1998). Most often, customary rights are ignored and overridden by statutory rights when creating parks and protected areas, with devastating effects on local livelihoods and cultures (see Chapter 3 Section 3.9, ECO-GENOCIDE and Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers). Once local social controls are lost, very often “Common Property Resources” become “Open Access Resources” which are “mined” and thus degraded. In the long-term, it will be critical for the state to recognize customary

tenure systems with their strong social controls, and to find innovative ways of integrating these systems into modern concepts of parks, hunting blocks and intensive resource management of natural resources.

“In Africa today a wide range of these different types of community conservation are functioning under different tenurial and institutional arrangements” (Barrow & Murphree, 1998).

However, over most of Sub-Saharan Africa, most CBNRM in communal areas is still quite top-down and state controlled. The land and wildlife is still owned by the state with the majority of benefits going to the state and private sector. Many outside “Western” values are being imposed on rural Africans by donor driven NGO implemented programs. Benefits are communal and are from a very narrow view of resource use (e.g., overseas trophy hunting, eco-tourism, rarely cropping) while individual entrepreneurs (e.g., traditional hunters, pit sawyers, charcoal makers, honey collectors, fishermen, etc. that tended to dominate under traditional tenurial systems (Chapter 2) have been marginalized and are still forced to access the resources clandestinely, namely “poach”. A recent study by Lindsey, *et al.* (2006) supports the retention of sustainable traditional user rights over natural resources, believing this increases the potential of successful conservation programs. For instance in the Kunene and Erongo regions of Namibia where CBNRM is practiced, natural resources provided the following benefits to households: 29% of the households (180 of 621) benefited from wildlife utilization, 19.8% (123 households) from building poles, 6.4% (40 households) from craft making using natural resources and 1.6% (10 households) from thatch grass. In the Caprivi region of 496 households, 67.7% (336 households) benefited from thatch grass harvesting, 49.3% (245) from reed harvesting, 40% (202) from building poles, 35.8% (178) from fishing, 24.1% (127) from wildlife utilization and 6.4% (32) from craft making. In the Caprivi and Kunene respectively, 69% and 84% used wildlife only for food within the household and immediate kin network, while 31% and 16% used wildlife for food and sales, mainly among the

poorer groups in the communities as opposed to wealthier segments as measured by livestock (Long, 2004).

It is only until recently that the state has begun to look at resource and land tenure issues as they apply to conservation. According to Barrow, *et al.* (2000), in East Africa, and this applies for most of Sub-Saharan Africa,

“groups and agencies involved with conservation have not until very recently become involved in the debate from a conservation and natural resource management perspective. This stemmed partly from their confidence in the nations’ conservation estates, and from the separation of conservation issues and daily national life; a flawed assumption”.

Let us hope that they are not too late in addressing this issue as many parks and protected areas in the beginning of the 21st century have become hard edged with a wave of human poverty invading them.

Decentralization Versus Devolution in Botswana

“The enabling process pursued in Botswana thus far has focused on decentralizing the right to manage and exploit the resource, rather than addressing ownership status. Local people do not get to make decisions about the size of the quota or the range of animals to be exploited; these decisions are made by the Department of Wildlife and National Parks” (Hitchcock, 2000b) (see Section 9.6.3.4, Botswana Community Trust Program).

Once allocated by government, a community quota management committee determines how the government allocated quota will be used. The local communities can retain some of the wildlife quota for traditional hunting, and/or lease some out to private safari operators as a means of gaining income or choose not to use it. The rules by which the communities operate are made by their members and their local institutions in conjunction with district authorities and the Department of Wildlife and National Parks. Certain members of the community feel that the hunting quotas restrict their access to wildlife compared

to the past when they could hunt freely during the days of “special game licenses” that allowed a more liberal and uncontrolled access to game through “traditional hunting rights” (Hitchcock, 2000b). Devolution appears a long way off. If and when communities have enough university-trained graduates, they may be ready to negotiate management of their own resources. Until then, the evolution of CBNRM will be stuck in Stage 3 with decentralization through co-management with government as opposed to true devolution: Stage 4.

Although the following is a separate policy issue, it is nonetheless linked to land and resource tenure (as is discussed in Chapter 11, Section 11.7.7.1, Lomé Convention and subsidized beef in Botswana). European subsidies of beef, accepted by the Botswana government, have given a temporary and artificial comparative advantage to cattle over wildlife resulting in short-term gain for a small elite. This has meant a major decline in wildlife and degradation of habitat. Some day, when these subsidies end and wildlife once again becomes the comparative advantage, the game populations will not be there to be taken advantage of by rural communities.

9.7.3 Failure to Integrate Cultural Ties towards Wildlife into CBNRM

“Conservation appears to be dependent on a complex and dynamic interaction between cultural values, livelihood issues, human relationships and economic benefits” (Junge, 2004).

“Redford and Stearman (1993 *In:* Lyons, 2000) state that biologists involved in conservation often ignore indigenous people's concerns in conservation dialogues. They sometimes claim to represent the interests of indigenous people without having the mandate or authority to do so. When programs fail to integrate traditional management practices and ideas, they are unlikely to benefit rural people (Lohmann, 1991 *In:* Lyons, 2000)...Even though indigenous communities may at one time have had effective systems for sustainable use, the social, economic, and technological foundations of those systems are often eroded or completely gone, and present-day communities are often less

concerned and equipped to conserve their resource base. The modern variants of traditional practices often do not meet the needs of growing populations and increasing aspirations (Redford & Stearman, 1993 *In: Lyons, 2000*)” (Lyons, 2000).

9.7.3.1 Spiritual, cultural and religious values often ignored in favor of monetary rewards

“Under most community-based wildlife initiatives, local people are expected to forgo their ‘opportunity costs’ of living with wildlife together with their ‘traditional access rights’ in exchange for strictly economic benefit schemes generated by wildlife uses by outsiders. Whereas many agriculturally based rural communities may accept the economic values attached to wildlife, other sources of security such as maintaining and consolidating significant social relations through mediated resource distributions are also important” (Marks, 2001).

Sustaining these resource networks while perpetuating cultural and social identities are central concerns for the survival of many small-scale communities in difficult environments (Anderson, 2001 *In: Marks, 2001*). Mayaka (2002) discusses failed delivery of promises, insufficient incentives and lack of power devolution resulting in ineffective state protection against encroachment, hostility of local populations and loss of biological diversity. He speaks of the importance of non-financial incentives such as democracy, pride and sense of ownership being overlooked for cash or in-kind incentives. “When prevailing conditions hinder their livelihood security, populations are likely to resort to subversiveness as a survival strategy” (Mayaka, 2002).

CAMPFIRE seems to have no capacity to deal with the spiritual dimension of conservation and natural resource management, failing to contribute to rebuilding indigenous knowledge and reintegrating it into conservation management (Sibanda, 2004 *In: Fabricius, et al., 2004*). It can be argued that this tends to be a serious flaw in most CBNRM programs.

In simple terms, wildlife alone will not provide enough “meat and money” or materialism to change peoples’ attitudes towards wildlife (see Section 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa). However, it is possible that what will be critical to saving wildlife and its habitat will be giving back to rural Africans their spiritual, cultural and religious ties to these natural systems such as access to their sacred forests, traditional burial grounds, traditional hunting and gathering rights. This also will also allow a percentage of individuals, the real entrepreneurs, to earn a livelihood from the diverse array of resources within the protected areas, something that is not a normal component of CBNRM.

In Africa, giving rural Africans such rights and privileges may be more important than “meat and money”, given the ever-growing human population. Most Africans cannot even afford the luxury of visiting a park and few have seen a wild animal other than crop pests such as warthogs, hares, monkeys and birds, as they have been cut off from their resources. Most see their only future as human-made systems, especially small-scale farms that are slowly engulfing many natural areas in Africa. Working with rural Africans to allow controlled access to “their” reserves and parks to carry out long-standing traditions and to meet their daily needs may be the only way of controlling illegal and unregulated harvest of resources from these areas, or worse, encroachment by small-scale farmers and loss of habitat. It becomes obvious that the needs and perceptions of rural Africans towards conservation in parks and protected areas are worlds apart from what an urban elite, be it in Sub-Saharan Africa or the West, wants from these areas. While the needs of this urban elite (leisure, escape from the pressures of modern society) and the global community (e.g., biodiversity) are important, too much emphasis has been placed on meeting these needs. Meanwhile, up until now little or no importance has been placed on meeting the utilitarian conservation needs of the interest groups, namely rural peripheral communities, who will ultimately determine the future of Africa’s wild areas. This will have to change if

parks and protected areas are to survive the more than doubling of Sub-Saharan Africa's population in 50 years to 1.8 billion, though this change alone will not save these areas unless they fit into a bigger picture plan for development on the subcontinent, which is discussed in the Chapter 14.

In the developed world, what has saved wildlife is not just its financial value, but also our ties to wildlife as an integral part of our culture and, as in Sub-Saharan Africa, hunting has often been seen as a rite of entry into manhood and male bonding: a father taking his son on his first hunt. In America and Europe, hunting camps are all about camaraderie, breathing fresh air and communing with nature and, even for non-hunters, escaping the fast paced life in the cities. Few people in the developed world depend on wildlife for survival, but they spend large amounts of money for cultural and spiritual and many would say religious ties to nature and wildlife. This has been a key to conservation in the West so why should it not be a key in Sub-Saharan Africa? If even a few of the traditions discussed in Chapter 2 still exist, then these cultural, ancestral and spiritual ties can be used and/or built on to develop a modern "African conservation ethic" built on tradition! For instance, hunting guilds can be reinvigorated and serve like modern-day hunting clubs in America, Europe and South Africa that train hunters and steep them in the culture, traditions, ethics and laws related to wildlife as in the guilds of old.

Yet, most CBNRM programs cut out traditional hunters and other resource users from parks, hunting blocks, forests and other protected areas. Traditional hunters then have to stand by while wealthy overseas hunters and tourists come into their hunting grounds and shoot their animals. Traditional hunters perceive overseas hunters as

"privileged individuals who are allowed to break laws that local people themselves are expected to uphold and abide by" (Fabricius, 2004, *In: Fabricius, et al., 2004*).

Speaking of how important traditional hunters are in conservation and the danger of alienating them, Marks (2005 *In:* Lyman & Child, 2005) concludes that

“their overlapping domains of knowledge about place, about religion, about destiny, about environments and their resources, and about leadership roles would seem to make local hunters associates (rather than perennial devils) of conservationists. Their bushcraft and roles have persisted over time, they are capable of supplying a local product in demand, they are widely distributed in space, they regulate their numbers, and their individual distributive representations and achievements are often a means for channeling and assuming ascendancy within their respective lineages. Their skills and knowledge are useful also in protecting human lives and crops. The existence of such local processes and expertise in wildlife seems supportive of co-management regimes together with effective devolution in some decision-making. Otherwise, once disenfranchised from projects, such local actors may turn their creative energies and talents to subverting the imposed system”.

ADMADE, Zambia

When the principal author evaluated ADMADE for USAID in 1992 (DeGeorges, 1992a), a number of professional hunters (PHs) explained that the ADMADE village game scout program was built around people who could read and write. Most traditional hunters cannot count as they can neither read nor write - their school being Mother Nature rather than a walled-in classroom. The ADMADE program assumed that revenues from building schools, wells, clinics, etc. would result in decreased off-take of wildlife. Game populations would remain stable or increase within the Game Management Areas (GMAs). Marks (2001) in comparing wildlife monitoring, conducted in collaboration with traditional hunters, close to villages between 1966-67 and 1988-89 shows a 50% decrease in numbers observed with this decline continuing between 1989 and 2001. This is based on the number of game harvested over time and the time to achieve this

success. In addition, while wildebeest numbers went up between 1989 and 2001, impala, warthog and zebra numbers declined. This is attributable to the influx of people to obtain project benefits²⁵⁸ and the institutional failure of ADMADE to change attitudes of local people towards wildlife, (Marks, 2005 *In:* Lyman & Child, 2005). Although ADMADE only started in 1987, much of the damage was done through alienation of the local hunters, who could have played a major role in stopping commercial and other illegal poaching had they been made part of the solution instead of being perceived as part of the problem. Ultimately, ADMADE has failed to integrate the cultural and spiritual ties of the local people to wildlife into the management of these areas, while economic benefits as will be seen are negligible at the level of household.

The first person to study the traditional hunters of Zambia was Dr. Stuart Marks. He is well-known for his study in the Munyamadzi Corridor (Marks, 1976; 1984). He was the first to document the ties of the traditional Bisa hunter to wildlife and the role of hunting and wildlife in religion, ancestor worship and leadership within the community (see Chapter 2). Traditional hunters provide both the community and urban centers important sources of protein, while earning a living. The Food and Agriculture Organization of the United Nations (FAO) estimates that 13.4% of protein in Zambia comes from “bushmeat” (Gibson, 1999). Marks estimated that in certain parts of the Munyamadzi Corridor, the average adult annually consumed 91 kilograms (200 pounds) of “bushmeat” in the 1970s (Gibson, 1999).

In a 1992 evaluation of ADMADE for the U.S. Government (DeGeorges, 1992a), traditional hunters felt cut out by the ADMADE program. They felt that they could carry out a number of tasks from village meat provision as the government

²⁵⁸ Linked to drought and increasing elephant numbers both of which adversely impacted agriculture

run scheme was failing, serving as trackers on village game scout teams and infiltrating poachers' rings. One group of traditional hunters said,

"We feel stabbed in the heart that the white man can come from far away to hunt, but we are not allowed to hunt". Another group of hunters said, "We have a disease passed on to us by our forefathers. It is in our veins and runs in our blood". When asked what disease they had, they said, "We are hunters" (DeGeorges, 1992a).

Many modern-day sport hunters understand this instinctual drive linked to our ancestors and our cultures. As with conservation throughout Sub-Saharan Africa's history, ADMADE drove hunting underground from use of selective rifles to non-selective and often destructive snaring (Marks, 2005 *In: Lyman & Child, 2005*) as opposed to working with local hunters to devise programs that legalized and controlled traditional hunting. Conservation was being moved in the wrong direction towards Stage 1, Conservation Against the People.

"Conflict between local people and park authorities is widespread in Africa and is exacerbated by the annexation of further areas as reserves for trophy hunting. Indignation at the hypocrisy of state interventions which prohibit local hunting but allow foreigners to hunt the same areas all in the name of conservation is keenly felt" (Colchester, 1994).

However, from about the time ZAWA was formed (1999/2000) traditional hunting quotas have existed in Zambia and though the cost is low, it is often unaffordable to local hunters living subsistence lifestyles. This local hunting quota also tends to be too low, with a bias in favor of higher trophy hunting quotas that generate significant income for ZAWA (*Chomba, pers. comm.*). Thus poaching continues.

CAMPFIRE, Zimbabwe

While issuing overseas sport hunting permits to generate income from wildlife, CAMPFIRE fails to recognize the Tonga and other indigenous peoples' (e.g., Shangaan) spiritual needs for hunting that have to do with healing the mentally sick and worship. As one elderly Tonga explained,

“Our people now die from mental illness because they can no longer hunt, as this is prohibited. We are told that we cannot kill animals, such as elephants and the eland. We wonder if the white men from overseas are coming to kill these animals in order to meet their own spiritual needs or maybe to heal their own mental illness. The law forbids the Tonga from killing animals. Why are white people allowed to kill animals and we cannot? If it is bad for Tonga to kill animals, it is bad for white people to kill animals” (Sibanda, 2004 *In:* Fabricius, *et al.*, 2004).

Xaxaba San Community, Kopano Mokoro CBO, Ngamiland 32 (NG32), Botswana

Elders argue that CBNRM has replaced their traditional subsistence hunting in which only they and God were in control with a situation where they are at the mercy of the government, safari operator, global economy and regional politics (e.g., radical land reform in Zimbabwe scares away tourists from all over Southern Africa) (Madzwamuse & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004). Commercial safari operators still give preference to employing outsiders and of 15 safari lodges and camps interviewed, only one operator mentioned the local population or culture in its brochures (Damm, Lane & Bolaane, 1998 *In:* Madzwamuse & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004).

9.7.4 Ignoring Constraints in Institution Building

The cultural divide was discussed at the beginning of this chapter, and the cultural ties to wildlife have been noted in Chapter 2. As a “cookie cutter” approach to democracy (see Chapter 11) has not worked, neither will the imposition of Western CBNRM institutions on rural people.

9.7.4.1 Traditional management institutions ignored in favor of Western institutions

A major outcome of CBNRM identified by Roe, *et al.* (2000)

“is the weakening of traditional authority and institutions, representing the negative side of the institutional achievements described above. In some cases this weakening of traditional authority is the outcome of a power struggle between traditional structures and new institutions that have been developed specifically to deal with CWM” (CBNRM).

“This makes the current disconnection between the formal CBNRM of projects and the more indigenous or traditional resource management systems of the real world in Southern Africa all the more unfortunate...But until the challenges of enhancing informal resource management systems are tackled, the livelihood benefits that CBNRM initiatives achieve for this region will be limited” (Turner, 2004 *In:* Fabricius, *et al.*, 2004).

Jones and Murphree (2004 *In:* Child, B., 2004a) conclude that many of the legal institutions sanctioned by governments and pushed by governments, Western NGOs and donors [e.g., trusts, communal conservancies, communal property associations (CPAs), Wildlife Management Areas (WMAs), Section 21 companies, etc.] under CBNRM that can enter into formal contracts with the private sector run contrary to the customary or informal constitutions that operate

in communities and are in conflict with the systems of decision-making in communities that are based on negotiation and consensus-building.

The institutional systems (e.g., trusts, section 21 companies, conservancies, etc.) imposed on rural communities tend to be designed by Westerners (e.g., whites) and/or African governments influenced by Western norms and standards. These institutions are often very complex and unwieldy, requiring highly trained people with accounting, management and marketing skills among others that currently do not exist in most rural African communities.

Traditional management systems are too often ignored in favor of Western systems imposed on rural communities. On the other hand,

“probably the most difficult aspect of working with indigenous peoples has been in identifying the appropriate indigenous institutions through which to mediate with outsiders” (Colchester, 1994).

This issue needs careful study and analysis to see where and if traditional systems can be utilized, resurrected and strengthened, so that people can relate to them as opposed to Western imposed institutions, and/or if the two can be integrated. While discussing the creation of pastoral institutions by outsiders, the following applies across the board to CBNRM,

“...When the interests of rich and poor coincide, then the poor will probably benefit more if the service is provided by an existing organization whose procedures are better rooted in the pastoralists’ own cultures, perceptions, and objectives than by new organizations whose constitutions and procedures are usually tailored to the convenience of central government’s legislation and bureaucrats...The establishment of new organizations with the assistance of a government or other outside agency may give the previously weak the opportunity to break away from the dominance of the powerful, but intervention needs to be prepared

to give continued political support, otherwise the poor will not stand up against the more powerful" (Sandford, 1983 *In:* Smith, 1992).

CAMPFIRE, Zimbabwe

Murombedzi (2003 *In:* Adams & Mulligan, 2003) states,

"Because institutional development in CAMPFIRE has taken the form of creating new 'formal' institutions, it has tended to completely ignore the preponderance of existing traditional institutions in most land and resource-management situations in many communities in Zimbabwe today"

and this has contributed to the alienation of communities from the CAMPFIRE initiative. He goes on to say that because CAMPFIRE ignores traditional rights and knowledge systems, it is informed by a centralizing and modernizing ethic that is contradictory to the decentralization process that is supposed to lead to community ownership over wildlife and other resources.

San of Xai/Xai, Botswana

Hitchcock (2000b) states that

"some of the people (San) of /Xai/Xai (Botswana) expressed the opinion that the kinds of institutional arrangements being proposed by the Botswana government and its advisors were too complicated and unwieldy to represent the stakeholders properly. As they put it, 'These are highly bureaucratic institutions.' What they wanted instead, they said, were institutions based on existing traditional resource management bodies (e.g., the *n!ore kxausi*) which have local legitimacy and are recognized as being responsive to the needs of community members. In 1997, it was noted that some of the members of the /Xai/Xai Trust were arguing in favor of using the *n!ore kxausi* (the territory owners/managers

for the community) both as sources of information and as managers of the resource base”.

Makuleke Community, South Africa

Koch (2004 *In: Fabricius, et al., 2004*) argues that the Makuleke community, who since 1996 own and co-manage the 25,000 ha of the northern Kruger National Park, have successfully merged traditional power structures with new democratic institutions.

Namibian Conservancies

Prior to conservancies, conservation authorities allocated a hunting quota to communal areas, the permit being issued in the name of the local headman (a part of traditional authority) who determined how the quota and benefits from wildlife would be distributed, along with customary laws (see Chapter 2, Section 2.1.3, Controlling Access to Wildlife Through the Chief, Section 2.1.3.1, Royal game and Section 2.1.8, Taboos as an Aid in Wildlife Management). In interviews with traditional hunters, it was found that there are already practices associated with local off-take that could form the basis of conservancy level dialogue to establish local rules and procedures for the management and access of wildlife. This would likely also apply to other resources (land, grazing rights, etc.). Today, community game guards report to the conservancy chairs, ignoring traditional authorities and customary laws (Long, 2004). Long (2004) recommends that conservancies should work through local level and existing traditional institutions such as churches, farmers’ unions, water point committees and kin and lineage groups to assure the sustainable management of natural resources. As noted above, to what degree do traditional authorities truly represent their people versus themselves and central/regional government today? This needs answering on a case-by-case basis.

9.7.4.2 Ignoring cultural constraints in institution building

Fairhead and Leach (2003) raise concerns that these “Western installed” local institutions are often far from being democratic, often serving a village elite, while at the same time allowing the predatory state bureaucracy with its rules and regulations to intrude into and control village access to and management of its resources, these structures becoming “a microcosm of the bureaucratic ideal of statecraft” giving an illusion of working with the community.

LIFE, Namibia, Nyae Nyae Conservancy

This may be one of the best-documented examples of the problems facing institution building in CBNRM programs. Young educated Africans will have to figure out, as with wildlife management, how to integrate these Western concepts with their cultural norms. If there is to be a chance for CBNRM programs to become functional in the long run, they will have to be Africanized.

The Ju/'hoansi were able to survive in the Kalahari as nomads. With the loss of almost all their land (see Chapter 3, Section 3.8.1, Land Compression Among the Last Hunters and Gatherers, Ju/'hoansi of Nyae Nyae, Eastern Bushmanland, Namibia & Chapter 9, Sections 9.6.3.5, LIFE, Namibia, Nyae Nyae Conservancy & 9.7.2.1, Devolution through policy reform, land and resource tenure) and depletion of wild resources on which they depended, they can no longer survive in the old ways. Alternative ways of life are being suggested and have been “pushed” by aid agencies and the government: growing crops, keeping livestock, making crafts and other business including the use of wildlife and other natural resources. However, the adoption of new livelihood forms requires changes in values, attitudes, social organization and the learning of new skills (Berger, 2003).

Socio-cultural constraints that make it difficult for individuals to represent, manage and demand accountability from leaders and staff have constrained the development of a modern management “culture and ethic”. The majority of conservancy members live in small, geographically distanced, independent villages, where decisions are made locally. This makes it difficult for members to understand and take on “ownership” and responsibilities as a conservancy, requiring new forms of authority and a sense of community-wide identity and decision-making (Berger, 2003).

The concept of periodic election of office bearers is not easily accepted, as this is not a past practice in Nyae Nyae. Members seem reluctant to elect new leaders and to replace them with younger people or more women. Those who were first “elected” onto the board were already known community leaders, and according to tradition “once a leader, always a leader”, a tradition of the *n!ore kxausi* (resource area leader) in the villages (Berger, 2003). These very same issues can be seen to be constraints to Sub-Saharan Africa adopting Western democratic processes that are discussed in Chapter 11.

A misunderstanding by outsiders is in assuming that what appears to be the egalitarian society of the San peoples will easily transform into an understanding and embracing of democracy and other Western institutions based on democratic processes.

“The tradition of hunter-gatherers was to live in relatively small independent family based groups, loosely linked to other groups with whom they established exchange relationships, but with no broad political organization and unity. As the San had a relatively individualistic way of life, the concepts of representation and ‘community’ service might also be foreign. Since even today, within each village there will be a *N!ore Kxausi*, a leader who is seen as ‘owning’ that village and the surrounding geographical resource area, the idea of several villages choosing one person to

represent them doesn't make sense. Hence, it is not surprising that there are challenges of creating a conservancy as a representative, democratically run organization with community wide participation" (Berger, 2003).

Social norms, discouraging women from attending meetings and training sessions away from their husbands, have been a constraint to increasing the number of women in conservancy leadership and employment (Berger, 2003).

There is a reluctance to elect youth and/or youth are unwilling to stand for elections or to volunteer, refusing the latter as they expect payment. With the loss of indigenous knowledge and skills and limited gain of alternative modern life skills, young people in Nyae Nyae perceive few options to support themselves on or off the land, employment by the conservancy being one of the few options. The heavy demands from family and village can put pressure on salaried individuals and this may contribute to negative behavior by some conservancy staff (e.g., corruption) (see Chapter 11, Section 11.6.3, Neo-Patrimonial Clientelism, the Big Man and "Cosmetic Democracy"). A society that resists the advancement of the individual over others is in direct conflict with modern concepts of advancement that rewards entrepreneurial effort (Berger, 2003). These very same constraints become issues in Sub-Saharan Africa's adopting of "free-market" capitalist enterprises and institutions.

Fisheries Management, Lake Malombe, Malawi

Decisions in fishing communities are taken through traditional consensus or by the autocratic authority of traditional leaders rather than through winner take all Western-style democratic processes (Donda, 2001; Hara, Donda & Njaya, 2002 all *In:* Hara, 2004 *In:* Fabricius, *et al.*, 2004).

9.7.5 Lack of Technical and Management Skills

“The success of CBNRM in Botswana, as elsewhere, will be measured in the long term by the extent to which communities are seen to be managing their land and resources sustainably. Some informants expressed concern that the Botswana program was successful in beginning a flow of benefits to local communities, but these communities had yet to begin to actively manage resources” (Jones, 1999a).

The absence of professional training still characterizes most CBNRM initiatives. A general problem for many community-based institutions is their lack of management and business skills (Barrow, *et al.*, 2000). Because rural communities lack appropriate skills, local-level organizations are ill equipped to deal with the complexities of the market, forcing them to be continually dependent on established professional monopolies (e.g., safari operators, eco-tour companies), which are often racially linked. The long market chain involves a number of middlemen, resulting in only a small percentage and inequitable portion of the product value going to the rural communities (Murphree, 2001 *In:* Baldus, *et al.*, 2001). Often, because the community does not fully understand the value of wildlife or the cost/benefits of doing business, they fail to negotiate a fair share of the net profits when this is allowed (e.g., in CAMPFIRE and Botswana, communities tender and/or auction their hunting quotas to safari operators). Although tendering and auctioning hunting quotas or even long-term joint ventures offer partial solutions, a community must still have an idea of the net worth of its product and be able to monitor the off-take to assure that someone does not come in high to get the contract and then abuse the resource to get out his/her profits.

Furthermore, communities are often given very sophisticated structures (e.g., conservancies, trusts), which require sophisticated skills by highly trained individuals that they do not have.

The kind of professional training needed by rural communities to manage these natural areas and their wildlife includes university training in wildlife management, eco-tourism, marketing, hotel management, business and accounting. In addition, post-secondary training is needed in professional hunting and tourism, guiding students through a minimal amount of formal education, but mostly through on-the-job training under an apprenticeship/mentoring program. Certain subjects can be mastered through short courses or workshops, but they are very few. Education is a series of building blocks and a number of years are required to develop the knowledge needed to run a community-based organization, undertaking budgeting and manpower allocations, while keeping decisions and finances transparent and one's actions accountable to the membership. One cannot become a wildlife biologist nor have the skills to thoroughly analyze monitoring data statistically as a means of making management decisions unless tertiary education is provided. Though many rural Africans are good hunters and naturalists, it can still take a few years of apprenticeship as a safari operator/professional hunter or tourism operator/guide to learn the other side of these professions, namely entertainment, relating to other cultures, camp management and cuisine and, most importantly, marketing.

Unfortunately, until today, few if any youth from rural Africa have been sent off for such education either by the private sector or by donors who have spent 100s of millions of dollars in such efforts. One has to ask why? The only answer the authors can come up with is similar to the arguments on “devolution”, namely that governments, safari/tour operators and NGOs, all of whom live directly and/or indirectly off the resources, want the upper hand. How best to keep the upper hand than by keeping the landholders, the rural communities, in a state of backwardness in which they lack the technical skills in addition to having little or no understanding of the value of their wildlife resources. Lacking this

knowledge, they are prepared to work for a pittance, and/or allow the majority of the benefits to go to the government and safari/tourism operator. In the case of the NGOs and safari/tour operators, educating rural Africans at the tertiary level might result in them working themselves out of a job!

The few that have been sent off for tertiary training (university) by Western donors often received inappropriate training in America and Europe to learn temperate instead of tropical climate management techniques and to be indoctrinated into eco-colonial “protected area management concepts”.

Murombedzi (2003 *In:* Adams & Mulligan, 2003) states that wildlife utilization under CAMPFIRE is racist and obviously alienating and humiliating for local populations, the safari industry being dominated by whites and there being very little participation by blacks in the skilled worker categories (e.g., as professional hunters, tour guides, safari and tour operators – that is owners of companies, and administrative management of such companies). The majority are “boys”, tent boys, cooks, trackers, gun bearers, skinners and mechanics. As noted in Chapter 2, the success of the hunt often depends on the skills of local hunters hired as trackers and gun bearers. However, they are paid the wages of unskilled labor, well below that of the professional hunter. When the day ends, those brave and skillful men go off to eat with the other laborers, not being given the honor and dignity that should be accorded them of dining with the client. This is typical throughout the hunting camps of Sub-Saharan Africa (see Section 9.7.6.5, Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders). THIS HAS TO CHANGE! The West had better wake up to the fact that if hunting and tourism are to survive in Sub-Saharan Africa, there will have to be a lot more Africans involved as active

company owners.²⁵⁹ A major exception is Namibia, where a concerted effort is being made by the safari industry to train trackers and skinners as professional hunters (they are already better at tracking than 99% of the professionals) – yes, the safari and tourism industries will become Africanized and the basis of this process will be through education. This very much scares many safari and tourism operators, NGOs and other “middlemen” who are taking advantage of Africa’s backwardness.

Formal training of rural Africans in nature conservation/wildlife management is critical to providing them with an understanding of the management, value and political issues associated with wildlife.

Mid-level training can be obtained in Africa’s classical wildlife colleges such as Mweka in Tanzania and Garoua in Cameroon, along with the more recent Southern African Wildlife College. However, these institutions need to move away from their colonial roots of training paramilitary forces to fight rural communities. The philosophy of these schools and their curriculum needs to be redesigned to train wildlife extension officers and ultimately community members to sustainably management the multitude of wild resources in their areas, not in cutting them off from survival!

²⁵⁹ Not as in Zimbabwe where in the 1990s safari operators were required to take on 50% partners, connected politicians and businessmen who were absentee partners collecting their percentage of the profits for the use of their name, but not actively participating in the running or learning of the business (SCI African Chapter, 1996; SCI African Advisory Board, 1997). Likewise in Tanzania, politically connected individuals often obtain hunting blocks and then sublease to white expatriate safari operators, picking up a paycheck as absentee landlords, with little or no idea if wildlife is being used sustainably. Having no vested long-term stake in Tanzania let alone the hunting block, there are a number of instances of subtenants shooting out an area and then moving on (SCI African Chapter, 1996). There is thus virtually no Africanization of the safari industry. Most of these politically connected black elites are from outside the hunting area and have no real interest in helping rural communities develop and eventually run their own wildlife business. In fact that is the last thing most of them would want to see happen. One could argue that these black elites, in the eyes of local communities are foreigners who might as well be a German, Frenchman, American, Spaniards or Englishman exploiting these resources.

On a positive note, Kahana (*pers. comm.*) states that at the Mweka Wildlife College, Tanzania, prior to 2000, the majority of students were funded by Western donors and a few by African governments. Today a high percentage of the students are privately funded from individuals to private safari and tourism companies. Statistics provided by Kahana (2005a) indicate that during the 2005/6 enrollment at Mweka, private entities sponsored 64% of the 85 first year students, 49% of the 59 certificate students, 89% of the 27 advanced diploma students, 20% of the five post-graduate students and 100% of the seven special course students. Unfortunately, Kahana (2005a; 2005b) indicates that of the Tanzanian private sector only Robin Hurt Safaris (hunting and eco-tourism) and African Environment Safaris (eco-tourism) funded one student each. Subsequently, the hunting companies of Robin Hurt Safaris, Danny McCallum Safaris, TGT Safaris and Tanzania Big Game Safaris funded one student each (Kahana, 2005c). The remainder of the private sponsors are overseas hunters and tourists, mostly Americans who meet up with youth working for the safari/tourism companies and decide to sponsor them. Graduation from wildlife colleges like Mweka or Garoua should prepare a person for a university level education and/or to work as higher paying skilled labor in the safari/tourism industry – possibly to even apprentice as a professional hunter (PH), though most PH's lack university degrees.

Tertiary education should be in Sub-Saharan Africa, by Africans about African ecology and management systems. Currently, the best and most cost-effective schools are in South Africa, which has knowledge gained by taking 300-500 years of Western resource management concepts and adapting them to African flora and fauna. Ian Parker (2004) clearly spells out this knowledge in the statement,

“White South Africans know more about managing their indigenous fauna than any people on this planet”

and it is precisely this knowledge that needs to be transferred throughout the subcontinent by sending youth to study nature conservation in South Africa's

universities. Initially, one of South Africa's roles, through the New Partnership for Africa's Development (NEPAD) should be to educate people from the rest of Africa, eventually linking to other tertiary institutions on the continent and bringing up their standards of education, which have declined drastically since independence.

As discussed in an earlier part of this chapter, the next step after returning to their communities will be for educated rural Africans to integrate this "Western" training into traditional knowledge and management systems, taking CBNRM to the next level.

Ultimately, the core objective of CBNRM is increased communal capacity for adaptive and dynamic governance of natural resource use, in which local capabilities are developed to handle change and negotiate the human impact on nature from past to present. Professional science can help them do this with the pre-conditions that local communities have 1) the right to plan, 2) the right to implement in their own manner, 3) the right to make mistakes and 4) the right to correct them. Professional science can then provide training, decision support and facilitation (Murphree, 2001 *In:* Baldus, *et al.*, 2001).

The above is said with one caveat; building capacity does not replace the need for full devolution of resource and land tenure to local communities. Child (2005 *In:* Lyman & Child, 2005) raises concern that because governments are reluctant to relinquish power and control over resources, capacity building is the CBNRM entry level by many Western donors and NGOs in the hopes that communities will eventually demand devolution. On its own, capacity building will not radically alter the political-economic status quo, at least not in the short-term. It could however, provide educated youth from rural areas prepared to fight for resource and land tenure of rural communities.

9.7.5.1 CAMPFIRE, Zimbabwe

What should be asked is why the CBNRM donor driven projects such as CAMPFIRE, which spent about US\$ 50 million over 12 years (Sparrow, *pers. comm.*) has to the authors' knowledge not sent one person from the rural communities off for university training, when most evaluations admit there is a need for capacity building? Are they afraid of building up a critical mass of educated Africans who could say, "Thanks for your help but you white boys and girls from America and Europe, well we don't need you any more. We can solve our own problems and find our own solutions to conservation and development. Thanks but no thanks! You can go home now"! Is that why we are not seeing more youth from these rural areas being trained at tertiary institutions by these Western Donor, Western NGO run conservation programs?

The first two Shangaan students who were sent abroad, Joseph Mundawu and Simon Steyn from Chiredzi in southeastern Zimbabwe, returned to their community at the end of 2003 from diploma studies in nature conservation at the Tshwane University of Technology (TUT), South Africa. Overseas sport hunters funded them. The major efforts up until now by NGOs such as WWF/Zimbabwe and ZIMTRUST have been short courses. To the authors' knowledge, no youth have ever been sent off from the hunting areas for university training by either the donors or safari operators, or apprenticed as a professional hunter. According to Abraham Sithole (*pers. comm.*), CAMPFIRE Association second vice-chairman and Chiredzi RDC indicated that arrangements are being made for these two students to become safari operators, the issue being finding an older "mentor" safari operator willing to train them and the rural community. The current political situation in Zimbabwe makes achieving this goal very difficult. As one of the students wrote to the principal author,

“The economic situation here is the worst in history, no employment, no investment in the country. There is a food crisis. The one and half years that I have stayed here at home have made me one of the poorest men” (Steyn, 2005). Upon telephoning the author, one of his first utterances was, “We are starving to death down here”.

Thank you President Mugabe! It is now 2008, and both students have fled the collapsed Zimbabwe economy to South Africa, pursuing further studies in nature conservation.

9.7.5.2 ADMADE, ZAMBIA

Since the development of ADMADE/LIRD programs in the late 1980s, to the authors' knowledge, no youth from the community hunting areas have ever been sent off for university training or apprenticed as professional hunters by either the donors or safari operators. A proposal by safari operator Ronnie Sparrow of Fair Chase Safaris operating the Nyampala hunting camp, who lost out to Tudor Jones in the Munyamadzi Corridor back in the early 1990s, planned to train at least one of the traditional hunters in the area as a professional hunter.

9.7.5.3 Tchuma Tchato, Mozambique

The Ford Foundation (Nimpuno, 2003) has funded two MSc. and one post-graduate diploma at the University of Natal in Pietermaritzburg, five diplomas and three certificates from the Southern Africa Wildlife College in the Kruger Park in South Africa and has held several short courses in English, computer skills, aerial survey techniques and CBNRM in Zimbabwe. It is believed that this training was given to government as opposed to the community, since, as noted above, this program has been used to consolidate government power at the local level. The safari operator, who, as noted, sold his company in 2005, at one time promised to identify and send off a youth from his area for university training, but this did not happen. It does not appear that money generated from the natural

resource base (e.g., income to the community from hunting) has been used for educational programs.

9.7.5.4 Cullman Hurt Community Wildlife Conservation Project, Tanzania

To the authors' knowledge, no youth from the hunting areas have ever been sent off for university training by either the donors or safari operators. In fact, the first student whom Robin Hurt Safaris is sending off, a former employee, Gladys Lendii, a Maasai woman, is being sponsored by the Shikar Safari Club (overseas sport hunters).²⁶⁰ She studied nature conservation at the Department of Nature Conservation, the Tshwane University of Technology (TUT), South Africa in 2004. Previously, Safari Club International (overseas sport hunters) sponsored Edward Mbarnoti for the same education at the same institution. He is back in Southern Maasailand working with a Maasai NGO, and in 2007 will begin his B-Tech at TUT.

Currently, few in the communities have the ability to manage benefits coming from hunting. Sally Capper, project director, (2001), agrees that the responsibility of the funds from the Cullman Hurt program should be with the villagers. The catch 22 is that at times corrupt village officials do get caught but usually after the money has disappeared.

“Our problem is that we have to show that we have put good effort into Community benefits. We get more and more pressurized every year. It's no good saying 'well we gave them the money, it's now their problem.' We are expected to produce positive results and have something to show at the end of each year”.

²⁶⁰ As noted earlier, since then Robin Hurt Safaris has sent 1-2 students off to Mweka Wildlife College, Tanzania so the idea is beginning to take hold as other safari operators join in.

Her idea is to train people in bookkeeping and basic accounting. In many places the Cullman Hurt program hands out cash for specified items and this money is taken back to the villages for payments and purchases. Making things as transparent as possible, the Cullman Hurt program informs as many people as possible of how money is spent, so that the “people” become the watchdogs over wildlife.

“In the end, we can't baby-sit eternally. It has to be the community's. It's an easier option for the villages to have us look after the money and to be responsible, as it takes pressure off them”.

Ms. Capper would like the Wildlife Management Areas (WMAs) to come online so that their institutions can be handed this responsibility, but she is concerned that they are still a long way away from full implementation. However, the communities will need to develop trained members and the institutional capacity to run the WMAs, including managing wildlife, negotiating joint ventures with tour and safari operators and/or setting up their own companies and handling finances in a transparent and responsible manner. Once again, it is believed that tertiary training of youth from the area will be key in the long-term success of WMAs as with most programs of devolution.

On the one hand, functional WMAs may not be in the interest of the private sector or government. On the other hand, creating WMAs without appropriately trained community personnel could be equally catastrophic, setting this process back for years. Education is thus critical in parallel with adoption of appropriate policies such as the WMA process. This is an issue across the subcontinent.

9.7.5.5 Botswana Community Trust Program

Matota Teko of the Yei tribe and Boipuso “Killer” Mangurunga of the Hambukushu tribe, both from the Okavango Community Trust, returned to their communities at the end of 2004 after studying nature conservation at the Tshwane University of Technology (TUT), South Africa. Safari Club International (overseas sport hunters) sponsored them. They are both working for the trust as general secretary and treasurer respectively.²⁶¹ In 2005, Tlhokomelang Ngaka, the first San woman to study nature conservation at a tertiary level returned to her people the //Anikhwe River Bushmen in Ngamiland, while continuing to study for a B-Tech at TUT. American sport hunters have sponsored them all. To the authors’ knowledge, no youth from the hunting areas have ever been sent off for university training by either the donors or safari operators.

9.7.5.6 LIFE, Namibia, Nyae Nyae Conservancy

To the authors knowledge, LIFE, which spent US\$ 25 million²⁶² over 12 years with still another five years of funding to go (Weaver, 2003), has never sent anyone off for university training from Nyae Nyae Conservancy. Currently, in the Eastern and Western Bushmanland conservancies, one student – the first San to study nature conservation at a tertiary institution (university), Paulus Arnold, returned from the Tshwane University of Technology, South Africa, at the end of 2003, having been sponsored by Safari Club International (overseas sport hunters). He is working as an assistant land use planner and nature conservationist for his community N≠a Jaqna Conservancy, Western Bushmanland.

²⁶¹ Boipuso “Killer” Mangurunga, Hambukushu, Gunotsoga Village, Okavango Community Trust, Botswana, initially employed by the trust is currently serving ten years in prison for getting an under-aged girl pregnant and refusing to marry her.

²⁶² Jones (1999b) indicates that USAID provided US\$ 14 million between 1992 and 1999 for the LIFE Project.

Hitchcock, (9n.d), explains the following goals of capacity building by the Namibian LIFE Project,

“A central feature of the LIFE Team approach is its commitment to the sustainability of the CBNRM program after the LIFE Project is over. The strategy is to build institutional capacity to monitor and maintain the natural resource base, strengthen the development of local and regional expertise in CBNRM, assist the participating NGOs, Community-Based Organizations, and communities to develop plans for shifting the financing of recurrent costs to the income generated by the community-based activities, and work out strategies whereby program efforts can increase the well-being of people over the long term. Several strategies are being employed by LIFE in its efforts to promote sustainability. Some of these efforts include (1) Employment of Namibian counterparts for expatriate positions, with the expressed objective of transferring skills and providing on-the-job training; (2) Recruiting local or regional consultants whenever possible, recognizing the considerable talents available in the public and private sectors; (3) Utilizing local and regional institutions to provide short-term training; and (4) Involving GRN (Namibian Government), NGO, and CBO staff in exchanges with other organizations in the region, thereby broadening their experience and providing opportunities for networking and forming collaborative relationships”.

It never mentions selecting youth from the rural conservancies and sending them off for university or other advanced training (e.g., hunting guides)! It never talks about having local people trained to be wildlife/protected area managers, to run safari and tourism operations or to be professional hunters. Why?

After spending millions of dollars of donor money, it is not evident that any individual has ever been sent for training at this level by the USAID LIFE project, although money has been invested in many workshops and short courses. To the authors’ knowledge, no youth from the hunting areas have ever been sent off for university training by other donors or safari operators. In 2003, the Working Group of Indigenous Minorities in Southern Africa (WIMSA), based in

Windhoek, was sponsoring 11 San students from Namibia and Botswana for tertiary education (Thoma, 2003a). Likewise, Volker Grellmann of the Eagle Rock Hunting School in collaboration with the Namibian Professional Hunters Association (NAPHA) is training trackers and skinners from game ranches as hunting guides, which is their first step in professional hunting:

- **Hunting guide**, which is the entry phase limiting hunting to the farm on which the hunting guide is employed;
- **Master guide**, which requires a minimum of two years of hunting guide experience, permitting the master guide to hunt on his farm plus two other properties;
- **Professional hunter**, which requires two years of master guiding and/or two years of full apprenticeship in a safari company, giving hunting privileges on all hunting land where landowner permission is acquired; and
- **Professional hunter-big game**, which requires a PH license, passing an additional examination focusing on dangerous game; in the future a two-year big game apprenticeship is envisaged.

They must be lauded for this pioneering effort of which the governments and professional hunting associations in Sub-Saharan Africa should take notice. Mr. Grellmann and NAPHA's next step must be to move into the communal areas.

9.7.5.7 SCP, Tanzania

To the authors' knowledge, the Selous Conservation Program (SCP) has only ever sent youth off to the national Community-Based Conservation Training Centre, Likuyu SeKhamaganga, Tanzania (Baldus, *et al.*, 2003). Two courses are offered there, catering for people from rural areas with primary education:

- A village game scout training course, which focuses on practical fieldwork; and
- A community-based conservation training course for village leaders, natural resources committees and community-based organizations.

These tend to be one-month short courses. To the authors' knowledge, no youth from the hunting areas have ever been sent off for university training or to Mweka Wildlife College by either the donors or safari operators.

9.7.6 Getting the Economics Right

9.7.6.1 Revenue streams directly to communities

At present, most revenues derived from wildlife are collected by the state and then only a small percentage of this is passed on to the communities. This creates conflict and demotivation. There is a strong risk that the resources are still perceived as "open access", controlled by the state. It is better for the community enterprises to be paid revenues directly from the sustainable use of their natural resources and then be taxed on these revenues. This promotes fiscal clarity and accountability. Receiving revenue directly from the harvest of the resource should help develop a feeling of ownership of the resource as "common property" and thus stewardship over its security/survival.

ADMADE has a centralized revolving fund, which, as described, does not work (see Sections 9.5.2 and 9.6.2.2, ADMADE, Zambia). The Wildlife Division of the Tanzanian government collects revenue from hunting and, as described, passes on the "25% retention fund" to local government with little or nothing getting to the producer community (see Sections 9.5.3, Cullman Hurt Community

Wildlife Project, Tanzania, Section 9.6.3.6, SCP, Tanzania and Section 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa, SCP, Tanzania). CAMPFIRE is similar. A mid-term evaluation of CAMPFIRE in 1998 by USAID estimated that only half of the Rural District Councils (RDCs) shared revenues with the producer communities (e.g., wards and villages) (Hasler, 1999). The Cullman Hurt program keeps revenue and only allots it to communities once they have defined a project. In most cases, the communities are not given this money directly but through employment or the purchase of building materials, thus failing to learn fiscal responsibility. Funds from the *Tchuma Tchato* program in Mozambique go to the government, which used to pass the money on to the villages, but now has created another bureaucratic structure between the people and their revenue (Nimpuno, 2003).

Revenue goes directly to community structures in newer programs such as the Botswana Trust and the Namibian LIFE program. However, as is described below, there is a need for better accountability and transparency in terms of what happens to this money.

9.7.6.2 Stop taxing the full value of the community’s wildlife

The current retention of trophy fees by government as practiced in most CBNRM programs is akin to asking a farmer to pay the full value of his cow each time one is slaughtered. Under such circumstances, why would anyone want to keep cows or wildlife? The communities, as on private game ranches in Southern Africa, must not only be given land and resource tenure, but must also be allowed to keep the full revenue derived from their resources. In turn, like any company, the community-owned safari companies being suggested can pay income tax like any private sector operation. By taxing the community in this manner, hopefully, they will take ownership over the wildlife just as they do with their livestock.

Baldus, *et al.* (2004) and Baldus, Kaggi & Ngoti (2004) with regard to the WMA process in Tanzania sum up the problem very clearly,

“The communities must be allowed to keep all the income from and all the fees from photographic tourism and tourism (overseas hunting) and resident hunting on their land. Why should a farmer be allowed to keep all the cash from selling a cow, but if he sells a buffalo, for which he has been given user rights, he has to share the proceeds with the Government. Instead of benefit sharing the WMA should pay taxes so that the Government gets its appropriate share too...If the wildlife remains a public good it will soon be exterminated outside National Parks and Game Reserves”,

and the national parks and game reserves will be next on the hit list!

9.7.6.3 Accountability, transparency and the creation of capitalist structures within communal systems

“Corruption and nepotism seem to be a danger in all Southern African (CBNRM) case studies where benefits have started flowing, and the fear of this might be the underlying reason for much of the intra-community conflict observed in the sub-region” (Roe, *et al.*, 2000).

For many reasons, corruption and nepotism are pervasive across Sub-Saharan Africa from CBNRM to business and governance (see Chapter 11, Section 11.6.3, Neo-Patrimonial Clientelism, the Big Man and “Cosmetic Democracy”). The lack of good governance and accountability (e.g., outside auditing) results in little incentive to pass on economic benefits from wildlife to the rural poor (LWAG/DFID, 2002), at the level of national government, local government and even at the level of community-based institutions.

Misappropriation of funds at all levels in Africa is a problem; Westerners commonly call this corruption. In the case of Africans, misappropriating funds might be considered taking care of the extended family or the right of the “chief

and his entourage" to take the majority of the benefits. There is thus a conflict of cultures. In the purest sense, CBNRM is a form of communism in which there should be equity in sharing. Stagnating and/or declining per capita GDPs exasperate these actions.

Roe, *et al.* (2000) conclude that CBNRM

"has the effect of shifting the locus of conflict from external to internal. Communities, previously unified in conflict against a common 'enemy' in the form of the state conservation authority are now divided internally over access to power and benefits".

The reality of most of these programs, as in Russian communism, is that a few political elites (government, safari/tourism operators and NGOs), in the name of the community expropriate most of the benefits from conservation, while the majority continues to live in abject poverty with little or no opportunity for advanced education and where individual entrepreneurship (e.g. traditional hunters, fishermen, sawyers, charcoal makers, honey, thatch grass and medicinal collectors) is suppressed in the name of conservation. Ironically, it is the West, their donors and NGOs, though they fought against the idea of communism and helped to bring about the fall of the Iron Curtain, who are the strongest supporters of this communist ideology. We know that Russian communism failed and if we are not careful, CBNRM could be heading down this same road, where local communities, but especially individuals, become disenchanted because of seeing few benefits. The real question that then arises is how to structure these CBNRM institutions and what kinds of checks and balances to put into place so that they behave more like a capitalist than a communist structure?

In America today, there are examples of worker-owned companies, in which each worker has a share in the company and receives a percentage of annual profits. CBNRM might be considered as a local community owning a factory without

walls in which the product is a trophy and/or an experience. Other products from these natural areas that allow for individual entrepreneurialism are timber, charcoal, fish, thatch grass, honey, other wild foods and medicines. The African Advisory Board (AAB) (AAB, 1999) “Community Guidelines” recommend following the most advanced Botswana Model, where a community trust is created, with elected representatives from each village sitting on a board of directors that is the key decision-making body – basically a community-owned business. As has been discussed, there is no reason why a community could not choose a traditional management structure over a trust. Regardless of traditional versus modern management structure, corruption is still a problem just as it is in the West. As with any business being run for shareholders worldwide, the African Advisory Board recommends external auditing in CBNRM programs, with the results being made public to the community in order to keep everyone honest. Likewise, as discussed, a lack of trained personnel to deal with managing both the trust and the natural resources is a major shortcoming to be overcome.

Beyond this, such structures and the communities they represent must be allowed to go through various growing pains, experience and deal with corruption, learning fiscal responsibility and accountability to their constituency. This will all be part of the “growing-up phase” of CBNRM as rural African communities are brought from subsistence into cash economies. Most importantly, the governments need to let their control over wildlife go, becoming facilitators, providing decision support and monitoring the results.

The following are illustrative of what is believed to be an endemic problem in CBNRM programs in Sub-Saharan Africa.

Missing Money, Okavango Community Trust, Botswana

At the end of 2003, the two students studying nature conservation at the Tshwane University of Technology returned to the Okavango Community Trust that controls hunting/tourism blocks [Ngamiland (NG) 22 and 23]. Wilderness Safaris, an eco-tourism venture, has generated US\$ 400,000/year for the community over the last five years, amounting to US\$ 2 million. A white trust manager and a trust board, whose head is illiterate, controlled this income. On arriving, the two students and a new white manager found the bank account empty. An external audit is being conducted to determine how this money was spent and/or absconded (*Mangurunga, pers. comm.*). This example is typical throughout community programs in Africa and demonstrates the crying need for external auditing and reporting systems as the basis of any such endeavor.

Boggs (2004, *In: Fabricius, et al., 2004*) notes corruption and the lack of accountability in the Sankuyo community of Botswana.

Missing Money, ADMADE

As noted under Section 9.6.2.2, ADMADE, Zambia, approximately US\$ 1 million in the government controlled “revolving fund” was unaccounted for, and what money made it down to the community level was often enjoyed by a few, mainly those living in the chief’s village.

9.7.6.4 CBNRM will not create a “middleclass” in rural Africa

CBNRM “benefit-based models are based on an incomplete understanding of the economics of community conservation and of the nature of wildlife benefits. Over the long term, they may neither lead to community welfare improvement nor contribute to wildlife conservation. Benefit distribution is a necessary, but in

itself may not be a sufficient condition for communities to engage in wildlife conservation. Whether or not communities have economic incentives to conserve wildlife, and whether or not they are economically better off in the presence of wildlife, goes far beyond ensuring that a proportion of wildlife revenues are returned to them as broad development or social infrastructure benefit (e.g., schools, boreholes and clinics)....benefit-based approaches to community conservation are based on the economic rationale that although wildlife has a high economic value, local communities - who are often already economically marginalized - receive little of this value, and therefore have little incentive to conserve wildlife because they do not economically gain from doing so. Benefit-based approaches require that wildlife conservation simultaneously generates national benefits (which will justify wildlife conservation overall), government revenues (which will provide funds to distribute to communities) and community benefit...This requires a redistribution of wildlife benefits, which are currently balanced in favor of the people who live outside wildlife areas (tour and safari operators, government bureaucrats, national treasuries) and often outside wildlife-rich countries (NGOs, rich tourists and sport hunters). If wildlife has little or no value to local communities, there is no reason why they should conserve it" (Emerton, 1998a).

While many people support the concept of people benefiting from wildlife, very few people have looked closely at quantitative figures. CBNRM, unfortunately, has been heavily politicized in the international arena such as at CITES (see Chapter 10) and CBD, where Western animal rights and sustainable use groups fight ideological battles, in many cases without knowing the reality on the ground. In some cases, the hunting fraternity sweeps the dust under the rug and in other cases, it is spread for all to see by the animal rights groups. Neither case, placing CBNRM on a platform to be aggrandized or trying to turn it into a pariah, will help CBNRM evolve where it counts – on the ground. Very often, the total benefits are quoted instead of what really counts: household benefits. Sachedina (2006) provides an excellent analysis in the Tarangire ecosystem, where common property benefits only and the lack of benefits at the household level fails to change attitudes of the population; wildlife and conservation being seen as a

threat to land tenure and livelihoods. We need to be honest about CBNRM and what it can really hope to accomplish economically, culturally and spiritually for rural Africans, because ultimately they will decide on the future of wildlife and they must make CBNRM evolve into a sustainable process. First of all, CBNRM as currently practiced, mainly based on safari hunting, offers limited prospects for individual employment.

Meanwhile, on the ground, people are living with wildlife and are making daily choices as to whether they should continue co-existing with wildlife, regardless of the above ideological battles. We need to realize what reality is for these people and what it is going to take for them to continue living with wildlife in the long-term.

The relationship between human population densities and the abundance of resources determines the potential and viability of CBNRM programs. Less densely populated areas where the Big 5 [lion, elephant, leopard, buffalo, rhino (currently not hunted except on private ranches in South Africa, and then mainly the white rhino)]²⁶³ exist can make the difference between financial returns which are less than US\$ 1/ha without these species to as much as US\$ 5/ha which can be realized by the community²⁶⁴ when they are part of the hunting quota (IUCN/SASUSG, 1997).

²⁶³ In 2004, CITES allocated five black rhino each as hunting quotas to South Africa and Namibia (see Chapter 10)

²⁶⁴ The gross/ha accruing to the community, safari operator and government is much higher. If the community obtains a minimum of 10% of the gross (does not separate out income on private and state lands meaning percentage to community likely much higher) (Khumalo, 2005), the above amounts would increase from US\$ 10/ha without the Big 5 to US\$ 50/ha/yr with the Big 5 as a gross value for the entire industry. Similarly, Child (1995) found that the gross value of wildlife on game ranches was US\$ 10.70-11.83/ha/yr (few game ranches offer the Big 5) compared to US\$ 4.24/ha/yr for cattle, while the net value was US\$ 3.53-4.48/ha/yr for wildlife and a negative US\$ -1.42/ha/yr for cattle on game ranches in Zimbabwe.

As things stand today, in most CBNRM programs, unless the human population relative to the natural resource base is low, the one-dimensional benefit-based approach alone from “off-farm” assets such as wildlife - normally hunting revenue and sometimes tourism revenue - will not significantly improve the lives of the rural poor at the household level. Jones and Murphree (2004 *In: Child, B.*, 2004a) conclude that where the resource to demand ratio is low (e.g., scarce resources in relation to human population size), CBNRM initiatives promising the delivery of direct economic benefits are doomed, the configuration of benefits needing to be based on other values (e.g., cultural, spiritual, etc.) and/or access to more diverse resources found in the area (e.g., traditional hunting/bushmeat, fish, honey, timber, charcoal, wild medicines). Such benefits can contribute, along with agriculture, to household production schemes and can be a catalyst to development in addition to “common property benefits” from hunting such as schools, clinics, roads and boreholes. In fact, as currently practiced, it is doubtful in most cases that CBNRM will allow the majority in rural Africa to join the ranks of the middleclass. Only in Botswana, where the human population relative to the resource base is low, do household level benefits appear to be relatively substantial (Table, 9.7) and even by Western standards they are low. In most cases, even where the potential income/household is relatively high, these benefits usually go to common property development, households seeing little or no direct benefits.

As currently practiced, it is even doubtful that the common property benefits of schools (better education), clinics (better health) and boreholes (safe drinking water) from CBNRM can help make sure that children are healthy and well educated and able to compete in a global society. As discussed in Chapter 5, Section 5.4, HUNGER LINKED TO POVERTY, if a large percentage of children are mentally stunted from undernourishment/malnourishment because their families are either too poor to buy appropriate food and/or have been cut off from

accessing the diverse array of resources they need as a result of exclusionist policies of parks and protected areas, they will not be able to take advantage of even these common property benefits. Rural Africans are losing all around!

Note: Gross indicates total benefits divided among households. Often benefits never reach household, used for common property benefits and/or to run community organization (e.g., conservancy, trust, Section 21 company, association, etc.).

Prepared by principal author

On the other hand, it is also doubtful that “common property benefits”, which should be the responsibility of government, such as education, health care and clean water, will change people’s attitudes towards wildlife. Whether you hunt or not, your children still get to attend school, your wife still gets to use the grinding mill and your entire family can go to the clinic.

“A growing recognition that the provision of social infrastructure is not in itself a sufficient condition either to financially benefit land holders or to offset the economic costs that wildlife incurs to them (Emerton, 1998b *In: Barrow, et al., 2000*) has led to a shift in emphasis to building the capacity of landowners to develop their own wildlife based sources of income” (Barrow, *et al.*, 2000).

Thus, as currently practiced, most CBNRM programs are based on the creation of exclusion zones in which individuals and households are often poorer as a result of CBNRM because of having to forego access to the diverse array of off-farm resources from these natural systems that were a key to survival and in today’s world can be a major source of income for entrepreneurial individuals from the community. CBNRM generally ignores these opportunity costs (Emerton, 1998a) in favor of a very narrow source of benefits (e.g., eco-tourism, safari hunting) that generally benefits the community at a higher level (e.g., social infrastructure), but

places the above-mentioned entrepreneurs at a major disadvantage, often turning them into poachers. Jones and Murphree (2004, *In: Child, B., 2004a*) state that the structure of government bureaucracies, donor interests/biases (e.g., creating preservation areas) and NGO foci (e.g., biodiversity) tends to separate agricultural and natural resource issues, rather than seeing the two integrally linked, as do rural communities, as components of a livelihood system derived from a common biophysical resource.

Recent research shows that the net distribution of direct and indirect costs and benefits is highly skewed, with the rural poor receiving a very small share of benefits, while paying the lion's share of the opportunity costs of the set aside land. Poor peoples denied access to wildlife resources is often associated with a corresponding decline in access to forest resources, resulting in increased stress, fewer livelihood diversification opportunities and increased vulnerability. They found that enterprise development allowing benefit flows to individual entrepreneurs within the community could be a more effective mechanism for enterprise success than a community held equity stake (LWAG/DFID, 2002). Ideally, possibly through a community tax on the quantity of resource harvested, a percentage of net profits would accrue to the community for the purpose of developing common property benefits. This would be similar to local property taxes in the developed world that can be used to provide basic social services to the community.

What does this mean? Economic benefits from a “one dimensional benefit approach” (Emerton, 1998a), such as hunting and tourism, can play a role in changing rural attitudes towards wildlife, but must be integrated into other more abstract issues if they are to be of value. These attitudes are: 1) cultivating a feeling of ownership over the resource by rural communities, 2) integrating traditional resource users such as hunters (both auto-consumption and bushmeat),

wood cutters, fishermen, thatch grass collectors, honey collectors, collectors of animals and plants for the aquarium trade, etc. into the formal management of these resources, legalizing their access and helping them to maintain sustainable off-takes, 3) recognizing that rural Africans' religious, ancestral and spiritual ties to natural resources are different from those of Westerners, but that they can nonetheless play an important role in encouraging conservation and 4) being honest that until the majority of the gross turnover goes directly to the rural communities, even if they have to pay taxes, and not to the middlemen (e.g., governments, tourism and safari operators, or NGOs in the case of donor money) CBNRM has no chance of being sustainable and most importantly of changing attitudes! LWAG/DFID (2002) identify the failure of the majority of the wildlife-dependent poor to capture a fair share of the economic and livelihood benefits from wildlife compared to government and the private sector as a major constraint to CBNRM.

Emerton (1998a) explains that a major mistake is being made by the proponents of CBNRM in assuming that broad-based common property benefits are what communities want and need and that these benefits will convince people to conserve wildlife and its habitat without regard for the needs of individuals and their families to secure livelihoods and income from many of these wildlife conservation areas. She believes that a sufficient portion of benefit from wildlife must be captured as financial benefits - such as income, consumption goods and employment - which are received by all landholders in wildlife areas to a level, which exceeds the costs borne as a result of wildlife. In areas with a low resource to human population base, this may be difficult to achieve and such areas may ultimately give way to other land uses.

CAMPFIRE, Zimbabwe

Based on 1993 statistics, it was estimated that 70 wards in 12 districts were involved in CAMPFIRE, reaching 68,800 households or 550,000 people, which comprises 5.5% of Zimbabwe's national population (Child, 1995). Although, between 1989 and 1999, CAMPFIRE brought in US\$ 15,856,128 (Bond 2001a), which is from 7 - 8.4% (see 9.5.1, CAMPFIRE, Zimbabwe) to 10% of the gross turnover (Khumalo, 2005) only about 49.7% went to rural communities (Bond, 2001a):

- 49.70% to communities;
- 21.15% reinvested in wildlife management;
- 8.56% paid as the rural district council (RDC) levy;
- 1.90% invested in capital development projects and the RDC levy to support the CAMPFIRE Association; and
- 18.70% not allocated but retained by the RDC for the general account

After splitting this 49.7% between about 95,000 heads of households by 1999 (Bond, 2001a), it becomes relatively insignificant at that level (Table 9.8). As discussed, much of this money may not have gone directly to the households, but into common property benefits.

Hasler (1999 *In: Fabricius, et al., 2001*) estimates that the average maximum household benefit, including shared benefits, was SZW 100/household/year or less than US\$ 5/household/year. From the data in Table 9.8, this would appear to be a median income. The actual household benefit was <US\$ 2.25 (ZD\$ 45/year) (Hasler, 1999 *In: Fabricius, et al., 2001*), which also appears low compared to averages in Table 9.8.

1699

ExtractedFrom: Bond (2001a) with permission, WWF

Sibanda (2004, *In: Fabricius, et al., 2004*) estimates that in 1996, farmers tended to earn much more from other activities than from CAMPFIRE. In the Nyaminyami CAMPFIRE area, the average farmer earned US\$ 34.90 (ZD\$ 350) from small stock, a goat selling for US\$ 9.97 (ZD\$ 100), while in the same year, the mean household cash income from CAMPFIRE was US\$ 5.48 (ZD\$ 55) (Sibanda, 2004, *In: Fabricius, et al., 2004*).

With the average per capita income at US\$ 460/year²⁶⁵ (BBC, 2002), the only way that CAMPFIRE can make a serious impact is through pooling the income in a given ward to provide “common property” benefits such as grinding mills, boreholes, schools, clinics, road improvements etc. In most cases, the rural population is too large for income from CAMPFIRE to make a difference at a household level. Many politicians and critics of CAMPFIRE support the use of this income for common property programs as opposed to insignificant individual household dividends (Duffy, 2000). Murombedzi (2003 *In: Adams & Mulligan*) states that nowhere in CAMPFIRE has wildlife come to represent a viable mechanism for household accumulation, though it is seen as beneficial to the extent that it subsidizes local authorities (RDCs). Only in two wards, Mahenye and Masoka, are benefits per household comparable to household incomes in semi-arid communal lands with the wildlife revenues being invested in agricultural infrastructure and equipment, which in turn have the potential to improve individual household quantitative accumulation – it is stretching the tape quite a bit to call this a success.

CAMPFIRE benefits in cash and kind (community infrastructure) at household levels are clearly related to these ratios (resource/human population) and are highest where human population densities are low and wildlife resources high.

²⁶⁵ This likely reflects a disproportional level of income made by city dwellers, the actual rural incomes being much lower. Regardless, the CAMPFIRE household income is insignificant, if it ever gets to the household.

Significant income appears to happen in wards where population density is less than 20 people/km² (IUCN/SASUSG, 1997; Murphree, 1997). This implies that at much beyond this density, habitat for wildlife is significantly reduced in communal areas, even if they abut against a core protected area. In essence, people are creating a human fence, as described by Thomson (2003), where wildlife will not go. Since hunting is not allowed in the core parks, the communal lands provide little economic benefit as there is little game to harvest and/or it and other resources are harvested clandestinely since legal access in these core areas is not part of the current “game plan”. It is interesting that the above figure is close to the 15.4 people/km² Thomson (2003) to 15.6 people/km² (Hoare & du Toit, 1999 *In:* Magome & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004) beyond which females and young elephant move out of an area, which in turn would eventually draw bulls away (see Chapter 10, Section 10.4.5, Does CITES Help Southern African Elephant Conservation?). Trophy hunting of bull elephants brings in 60% of CAMPFIRE’s income. Thus, as human population densities reach a critical number, the major source of income is lost.

In Zimbabwe, the majority of plains game (antelope) hunting was on private land (until massive land invasions beginning in 2,000): 85-90% on private game ranches and 10-15% on conservancies. Conservancies legally join together a number of contiguous private farms with common policies and practices and no internal fencing. Most big game hunting is on state and communal lands (Carney & DeGeorges, 2000). Bond, *et al.* (2004 *In:* Child, B. 2004a) estimate that hunting on private land in Zimbabwe accounts for only 20-30% of total revenue earned from hunting, the rest coming from state and communal lands. Still, plains game from the private ranches is critical to the safari industry since it is not readily available in the communal and many of the state areas. What this implies, and what most people do not want to admit, is that CAMPFIRE is not changing individual attitudes towards wildlife. While the average person may not have the

means to hunt buffalo, elephant, lion and leopard, any plains game coming out of the game reserves/parks, which the CAMPFIRE areas surround, tends to be poached and eaten (Steyn & Mundawu, *pers. comm.*),²⁶⁶ and one might ask why not if the core protected areas are maintained.

Sibanda (2004 *In: Fabricius, et al.*, 2004) states that in the CAMPFIRE areas of those interviewed, 46% had received no benefits from CAMPFIRE, only 10% thought CAMPFIRE was about sharing benefits from natural resources, 53% thought it was just about conservation of natural resources, while 18% knew nothing about CAMPFIRE.

The two school teachers from Chiredzi, who studied nature conservation at the Tshwane University of Technology, South Africa, and are among the most educated people in their community, have no idea what CAMPFIRE has accomplished in their area, while, on the other hand, being well aware of what various church groups have accomplished. This demonstrates that CAMPFIRE is badly in need of a public relations campaign and/or has accomplished little or nothing in this particular area. More importantly, since the average person has no idea what, if anything, CAMPFIRE is doing in their area, attitudes towards wildlife cannot be expected to dramatically change (Steyn & Mundawu, *pers. comm.*).

CAMPFIRE has shown that the

“state and its local level institutions that include Rural District Councils (RDCs) are not interested in sharing benefits, including sharing revenue. Their concern is to keep as much revenue as possible for their own bureaucratic emolument” (Murombedzi, 1992 *In: Dzingirai*, 2004).

²⁶⁶Simon Steyn and Joseph Mundawu, School Teachers from the Chiredzi Communal Area, and Project Noah Scholarship Students, Dept. of Nature Conservation, Tshwane University of Technology, South Africa.

Locals in Sengwe, part of the Chiredzi RDC

“think CAMPFIRE is a fraud: ‘They promised us money and motorcars, which they said, would ply the villages. To date we are stuck here in Sengwe. There are no buses. We have no motorcars or anything that resembles them, other than these homemade sandals from worn out vehicle tires. Do not tell us anything about Campfire’” (Dzingirai, 2004).

Roe, *et al.* (2000) state,

“The Southern Africa report queries whether CWM (CBNRM) does in fact have an impact on environmental awareness of local communities and cites research by Murombedzi (1999 *In: Roe, et al., 2000*) and others in Zimbabwe as evidence for this: ‘People at Masoka in the Dande communal lands invite newcomers to immigrate into their area in the hope that this will stimulate infrastructure and transport provision, knowing that the increase in population will be to the detriment of wildlife’. The people at Sankuyo (Botswana) still, after two years of a very lucrative CWM, believe that wildlife and the responsibility to manage it belongs to the state (Boggs, 2000 *In: Roe, et al., 2000*), while communities at Dwesa do not seem to be concerned about the obvious negative trends in the ecological status of mussel beds that they harvest (Timmermans, 1999 *In: Roe, et al., 2000*)”.

In addition, it may very well be that, as in many rural areas of the developing world, allowing controlled access to wildlife and other resources by the community may be more important in getting them to “buy into” wildlife conservation compared to “common property” benefits, which are not readily seen as tied to wildlife conservation. Thus, allowing local resource users as community representatives to legally harvest excess wildlife coming out of the “core conservation area”, whether officially or by default, may be one of the most important contributions to conservation that is being undertaken in the Chiredzi area. This allows desperately poor people access to much needed protein. As noted (Steyn and Mundawu, *pers. comm.*), this practice is already happening, as

any plains game coming out of the Gonarezhou National Park is killed and eaten, but with little or no monitoring to observe the effects. The next step should be monitoring this off-take and the formal integration of traditional hunting into the management of wildlife in the area, including the park/reserve surrounded by the communal area. These two students have some interesting challenges facing them on their return. Roe, *et al.* (2000) argue that

“illegal or unsustainable use of wildlife and its subsequent decline is a result of the lack of rights and responsibilities of local communities for wildlife. If wildlife conservation is perceived to be of little value to communities because of the limited, or indirect, benefits they receive from it then they will continue to use it illegally rather than to conserve it”,

although in the above case one could argue that up until 2000, by respecting the boundaries of the park and by only harvesting the overflow, they were practicing good conservation, even if illegal.

Murombedzi (2003 *In: Adams & Mulligan*) concludes that CAMPFIRE and its revenue are “carrots” that actually constitute a constraint to accumulation at the level of households, since income at a household level is insignificant, while access to resources in the natural areas and expansion of agricultural land are forbidden because of land use planning restrictions, and the tsetse fly associated with wildlife restricts livestock. However, Murombedzi (1999 *In: Roe, et al.*, 2000) also argues that

“most CAMPFIRE wards invest their CAMPFIRE revenues not to improve wildlife management and therefore increase wildlife revenues, but rather to improve agricultural productivity in ways that are incompatible with wildlife. Agricultural extension services in CAMPFIRE areas continue to be geared towards encouraging the expansion of arable agriculture, rather than realigning land use to favor wildlife production”.

Reinvesting back into and expanding agriculture could result in habitat encroachment on wildlife areas and/or in increasing conflict between farmers and problem animals, in both cases resulting in declines in wildlife.

Since many of the CAMPFIRE areas are over-crowded communal areas, until the 2000 land reform, the major areas available for expansion would have been in the wildlife areas that they border, which would have been out-of-bounds, based on CAMPFIRE agreements. Unless drastic changes are made, where communities take ownership over wildlife and many natural areas while gaining the majority of the value from the sustainable use of wildlife and other resources, many of the parks and protected areas such as the invaded Gonarezhou National Park may be in jeopardy.

ADMADE, ZAMBIA

If one takes the income from wildlife that actually reaches the head of household, it is very little. The following is based on 1991 revenue from the Luangwa Valley (Table 9.9). Estimates are made only for the Munyamadzi Corridor, for which human population estimates exist for the period over which the economic data was provided.

The average of US\$ 17/household/year that may not actually go directly to the household, will likely not change the attitudes of rural people. ZAWA (1999) is concerned that

“both the industry and the local community have seen a relatively static level of income from the safari industry in recent years. There is justified concern that these levels are not sufficient to motivate and support communities to effectively protect wildlife throughout the more than 150,000 km² of Game Management Areas (GMAs). As a result the resource base is vulnerable to

degradation and decline, thus reducing Zambia's ability to compete in the industry. Any other means of protecting wildlife in these Game Management Areas without direct support and involvement of local communities are probably unaffordable and unsustainable...In recent years both clients and industry stakeholders have expressed disappointment and growing concern over the declining quality of safari products in many parts of Zambia. This paper will show these concerns are real, represent serious threats to the future of this industry, and require strategic policy changes on wildlife use if these threats are to be overcome".

Table 9.9: Luangwa Valley Game Management Areas (GMAs) 1991 revenue retained by communities from concession fees – ADMADE program

Source: DeGeorges (1992a)				

Like in most CBNRM programs, benefits tend to go towards “common property” benefits. As with CAMPFIRE, this money can best be used in community projects such as grinding mills, schools, clinics, etc. If a buffalo can generate Kwacha 4,000 (US\$ 40) for a traditional hunter from smoked meat sold on the Mpika Plateau (Marks, 1990), why should he stop hunting for a once a year US\$ 17 benefit that goes to the community and not the household, when he will likely hunt a number of animals throughout the year and may hunt for cultural and spiritual reasons as much as for monetary rewards. The traditional hunter is an entrepreneur turned into a poacher by communistic CBNRM programs driven by the West. Marx should be laughing in his grave! As a result, there has been limited buy-in by local communities as indicated by observations made by overseas hunters in ADMADE areas (Table 9.10).

Table 9.10: Summary of client perceptions from confidential questionnaire by 71 overseas hunters in ADMADE communal areas in 1998

Positive perceptions of safari hunting experience (%, sample = 71 clients)

Animal Abundance	Trophy Quality	Hunting Area	Professional Hunter	Hunting Camp	
39%	32%	37%	90%	85%	

Negative perception of safari hunting experience (%, same sample)

Land use activities:

Fishermen Disturbance	Bush Fires	Snares Found	Poaching Activity	Other Licensed Hunters	Tree Cutting	Village Encroachment
15%	17%	32%	39%	21%	25%	35%

Safari products:

Too few Animals	Poor Trophy Quality	Poor Camp	Poor Vehicle	High Fees	
13%	6%	3%	0%	23%	

Source: ZAWA (1999), U.S. Agency for International Development funded, public domain + permission, ZAWA.

This indicates that only about 33% of the clients were impressed with the trophy quality and abundance of game, while major conflicts existed with various land

uses that interfere with the normal exclusivity of safari hunting. Additionally, while on average only 6% of the GMAs have been cleared for settlement and farming, the area suitable for safari hunting is shrinking to 18% of the average GMA (ZAWA, 1999). This indicates that a combination of various resource extractions (e.g., traditional hunting, legal resident and non-resident hunting that overlap and compete with safari hunting, fishing, tree cutting, etc.) are either reducing the amount of game and/or pushing it into the least disturbed areas within the hunting block. One must ask if the development of stakeholder management plans could reduce these apparent conflicts?

The ZAWA (1999) conclusion that snaring is down due to collaborative efforts by local communities seems to be in conflict with observations by overseas hunters and the general decline in the status of GMAs to produce quality trophies (see Section 9.6.1.1, Zambia). It is furthermore in conflict with observations by Marks, who works closely with and monitors activities of traditional hunters, who provide records of how the hunting is done, at what distance from the village hunting takes place and how much effort is put in as relative indices of wildlife abundance (Marks, 2005 *In:* Lyman & Child, 2005). It is concluded that with regard to land use, disturbances from increasing human population pressures

“on the remaining hunting areas, resolving this problem is perhaps the greatest challenge the industry faces” (ZAWA, 1999).

LIRDp, Zambia

The next-door Luangwa Integrated Resources Development Program (LIRDp) targeted between 45,000 (Child & Clayton, 2002) and 50,000 (Child, B., 2004b *In:* Fabricius, *et al.*, 2004) people living in the Lupande GMA, Luangwa Valley. Prior to the creation of village action committees (VAGs) in the mid-1990s, as in ADMADE, there was mistrust by local people for the chief and the lack of

transparency in accounting for finances (Child & Clayton 2002). As in ADMADE, this devolution was initially resisted by the local chiefs. There are regular elections to the VAGs, a bank account, six-monthly audits and a high level of community participation (Child, B., 2004b *In: Fabricius, et al., 2004*).

Each VAG receives 80% of the revenue generated from the GMA (Child, B., 2004b *In: Fabricius, et al., 2004*). The remainder of the income goes to (Child & Clayton, 2002) (Section 9.8.5.2, LIRDP):

- Area development committees (ADC)²⁶⁷ 4%;
- Chiefs 6% (later they received an additional +/-2% from contingency funds); and
- Contingency 10% (reserved to employ ADC executive secretaries).

Village Area Groups (VAGs) on average allocate income as follows: 40% for common property benefits (schools, clinics, teachers' homes and wells), 10% to employ community game scouts, 40% for individual members (Child & Clayton, 2002; Child, B., 2004b *In: Fabricius, et al., 2004*) and 10% for VAG administration (Child & Clayton, 2002). Based primarily on overseas tourist hunting (sport hunting) in two concessions and some hippo culling, US\$ 220,000 is generated annually from which 20,500 adults received US\$ 5.37/person/year (Child, B., 2004b *In: Fabricius, et al., 2004*). Turner (2004 *In: Fabricius, et al., 2004*) estimates that 10,000 households receive US\$ 37.50/year gross, based on US\$ 220,000 direct revenue from leasing hunting concessions plus wage employment of US\$ 150,000. If one only looks at direct income such as wages, this may or may not be equally distributed throughout the community. If wages are discounted, the US\$ 22 gross/household/year is obtained. A single snared

²⁶⁷ "Each chief's area has an Area Development Committee (ADC) comprising between three and ten VAGs" (Child & Clayton, 2002).

impala was valued at US\$ 9.63 (Lewis & Phiri, 1998 *In:* Magome & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004), so, as noted above, with buffalo worth US\$ 40, why should individuals and/or households give up traditional hunting, the income from CBNRM in Zambia being insignificant to their livelihoods.

Cullman Hurt Community Wildlife Project, Tanzania

If cash is to be a practical option, the amount of revenue relative to the number of beneficiaries must be such that each share is a significant contribution to the recipients' pockets. If allocations for 2001 were to be given in cash to villages under the Cullman Hurt Community Wildlife Project, individual shares would have the following range (Clarke, 2001):

- Makao's allocation is \$3,377, its population 1,400; therefore shares per person would be \$2.41/year; and
- The most favorable ratio would be at Ukumbi Kakoko: allocation \$3,376, population 276 and cash per person \$12.23/year.

This would likely amount to between US\$ 14.50-120/household/year. Under these circumstances, community projects that address villagers' chief concerns (e.g., schools, clinics, grinding mills, boreholes) and problems seem a better proposition than cash shares for the foreseeable future (Clarke, 2001).

Tchuma Tchato, Mozambique

There are 11 communities or "villages" in the area with 1,863 families/households or 8,086 people living in the 2,500 km² area with a density of 3.2 persons/ km² (Murphree, 1995). Moçambique Safaris employs 15 persons in the field, who earn the equivalent of about US\$ 525 a month (assume this means US\$

35/person/month though not spelled out). Between 1996 and 1999, communities in Bawa received between US\$ 11,000 and US\$ 15,000/year from the revenues of the tourism operator in the area. In 2001, approximately US\$ 57,000 was paid to the government for trophies and license fees, of which 34.5% or US\$ 17,500 was paid to the communities (Nimpuno, 2003). Johnson (2004 *In: Fabricius, et al.*, 2004) estimates this income to be US\$ 12,000 in 1996 from safari concession fees. If the money was distributed by household, this would have amounted to between US\$ 5.90-9.39/household. To date there has been no distribution of income at the household level, though some people have argued for this (Nimpuno, 2003). Similar to other programs, money is used primarily for “common property” benefits, with grinding mills, schools, community shops and improving roads/transport to gain access to the market being priorities, among others (Nimpuno, 2003). As noted, the government conservation agents at the local level diverted much of this money for their own use (Johnson, 2004 *In: Fabricius, et al.*, 2004)

Makuleke Community, South Africa

To date, ordinary citizens have seen no material benefits from the contractual park. The collection of wild plant resources remains problematic and traditional hunting is forbidden (Reid & Turner, 2004 *In: Fabricius, et al.*, 2004). A gross income from safari hunting for the community of US\$ 50,000 translated to US\$ 10/household in 2001 (Magome & Fabricius, 2004 *In: Fabricius, et al.*, 2004). Child, *et al.* (2004 *In: Child, B., 2004a*) estimate that the Makuleke community currently earns about Rand 2 million (US\$ 308,000)/year from trophy hunting and luxury lodges are being built in this contractual park with benefits accruing to the community. RSA Community Organizations (2005) give the figure of Rand 3 million (US\$ 461,538) over four years generated from hunting for the community or US\$ 115,385/year gross. With 1,200 households (10,000 people) (DeGeorges,

1999a), depending on the figure used, this amounts to about US\$ 96-257 gross/head of household/year. If one assumes 15,000 beneficiaries or about 2,500 households as per Mahoney and van Zyl (2001), then income ranges from US\$ 46-123 gross/household/year depending on the figure used. Harvey (2006) uses a figure of 20,000 beneficiaries, at six to eight people/household. Based on the above information, this would amount to between 2,500 and 3,333 households, resulting in the same range of benefits for the 2,500 households to a low of US\$ 35-92/household/year. Agriculture and grazing livestock are not permitted.

Mahoney and van Zyl (2001) estimate that hunting revenue in 2000 earned US\$ 4.5 (Rand 35)/person/year. Anticipated revenue from hunting in 2001 was US\$ 101,912 (Rand 800,000) or US\$ 7 (Rand 53)/person/year. Assuming an average household size of six persons, this amounted to a household income of US\$ 26.75 and 41 (Rand 210 and 320) for 2000 and 2001 respectively. The CPA elected not to distribute the income, but to use it for community projects.

It is believed that as part of a signed agreement with Wilderness Safaris to build lodges, trophy hunting has been stopped (Mokono, *pers. comm.*). According to Chief Makuleke, Wilderness Safaris is anti-hunting (Harvey, 2006). It is unclear exactly how much income is being generated, but according to Mokono (*pers. comm.*) income at the level of household is very low.

Botswana Community Trust Program

Botswana may be one of the few places where the human population relative to the resource base is low, allowing for considerable benefits to local communities. The Botswana Wildlife Management Association (BWMA) has been able to provide some data as has anthropologist Robert K. Hitchcock. A key here is that even with relatively high ratios of resources to human populations and thus high

gross household benefits, little money appears as cash dividends at the household level (Boggs, 2004; Turner, 2004 all *In: Fabricius, et al., 2004*).

In Sankuyu, a community falling within Ngamiland block NG 34 of the Okavango Delta, the current annual revenues to the trust are about Pula 700,000, (US\$ 119,000), to be shared between about 100 households, (US\$ 1,190 per household) all from hunting (Peake, 2001). Boggs (2000) estimates an average income/year to the Sankuyu community of US\$ 174,167/year over a three year period from 1996-1998 for 340 villagers and US\$ 220,280/year averaging over a five year period from 1996-1998 (Boogs, 2004 *In: Fabricius, et al., 2004*) for 350 villagers.

Boggs (2000 *In: Fabricius, et al., 2001*) puts the value from wages, lease agreements, hunting quotas and levies at Pula 935,000 (US\$ 233,000) or US\$ 4,700/year/household for 50 households. However, going directly into Boggs (2000), US\$ 522,500/three years (Pula 2,090,000/three years) from 1996-1998 was made by 340 villagers, which amounts to an average of US\$ 174,167/year. If there were six to seven people/household, 50 families would be an accurate estimate or US\$ 3,843/household/year in benefits. Boggs (2004 *In: Fabricius, et al., 2004*) estimates direct financial benefits to 350 residents as US\$ 1,101,400 over a five-year period from 1996-2000 or an average of US\$ 220,280/year. Assuming 50 households benefiting, this amounts to US\$ 4,450/household/year. However, Turner (2004 *In: Fabricius, et al., 2004*) referring to Boggs (2004 *In: Fabricius, et al., 2004*), gives an estimate of 23 households, which would give one an estimate of US\$ 9,577/household/year. If the average income is about Pula 6,000 (US\$ 1,020)/head of household per year (Mangurunga, *pers. comm.*), they are significantly increasing their annual income by this additional revenue if it is distributed at the household level, a big question?

Boggs (2004 *In: Fabricius, et al.*, 2004) estimates that the Khwai Community Trust in the 1,815 km² NG 18 made revenue from selling hunting quotas at US\$ 240,000, US\$ 120,000 and US\$ 320,000, respectively in 2000, 2001 and 2002. Hitchcock (2001) places the February 2000 auction as selling the wildlife quota for Pula 1.6 million (US\$ 272,000). Hitchcock (*pers. comm.*) gives a population of 360 residents in this trust also having NG 19 of only 180 km².²⁶⁸ This amounts to an average of US\$ 630 gross/person/year over the three years. Assuming 35-50 households depending on the size of the average family, this amounts to US\$ 4,536-6,480 gross/household/year.

The Okavango Community Trust operating Ngamiland blocks (NG) 22 and 23 has opted out of hunting for the moment, but is considering putting one block out on tender for hunting in 2004. They currently net Pula 1.6 million (US\$ 400,000)/year from leasing these blocks to the eco-tourism company Wilderness Safaris that has a reputation for being anti-hunting.²⁶⁹ The trust consists of five villages with about 600 people/village totaling 300-500 families depending on the size of the families. Income from eco-tourism amounts to US\$ 800-1,333/family/year though up until now distribution to heads of households has not been practiced (Mangurunga, *pers. comm.*). In fact, as discussed in Section 9.7.6.3, Accountability, transparency and the creation of capitalist structures within communal systems, all of the income over the last five years appears to have been misappropriated - a nice way of saying stolen.

In exchange for the subleasing of some of the wildlife quota from the Controlled Hunting Areas (CHAs), the /Xai/Xai Tlhabolo Trust was promised to make as

²⁶⁸ Photographic area just below NG 18

²⁶⁹ Part of the agreement for Wilderness Safaris investing in lodges in the Makuleke community was the closure of hunting that had gone on for only a couple of years and consisted of a couple of elephant and buffalo/year

much as Pula 2,500,000 (US\$ 425,170) over two years (Hitchcock, 2003b).²⁷⁰ This would amount to US\$ 5,450/head of household/year for 39 households (Hitchcock, 2003c). It turns out that the safari operator, Bernard Horton (crossbow manufacturer), misled the community as a means of getting the hunting rights to their concession (Hitchcock, 2003b/11/16). A more realistic figure by 2002 from the safari operator was Pula 200,000 (US\$ 34,000 or US\$ 872/head of household) per year (Hitchcock, 2003d).

One of the problems with regards to work in the tourism industry is that often the San and other rural people obtain menial jobs as waiters, tent boys, etc. as opposed to company managers (Hitchcock, 2001). Education and work experience should slowly change this situation, where one day there will be local safari and tourism operators running community-owned or even individually owned businesses in the tourism sector.

LIFE, Namibia, Nyae Nyae Conservancy

Earnings by the Nyae Nyae Conservancy from 1997-2002 are contained in Table 9.11. It is estimated that there are 400 households in the Nyae Nyae Conservancy (Thoma, 2003b). Thus, average direct earnings, 100% from trophy hunting, from the Nyae Nyae Conservancy from 1998-2002 were about US\$ 48,415/year, which, if allocated at 65% to households (see Section 9.5.6, LIFE, Namibia, Nyae Nyae Conservancy, 35% operational and common property benefits), would provide about US\$ 79/household/year from 1998-2002. Additional income made by individuals is not equitably distributed, being biased towards a few households, as is employment by the conservancy, which would come out of the 35% portion of its direct earnings.

²⁷⁰ About Pula 5.88/US\$ in 2002(US\$ 0.17/Pula in Hitchcock, 2003c)

N\$ 7/US\$							

Extracted from: Berger (2003) with permission, WWF + financed by USAID public domain.

In 2003, the Nyae Nyae Conservancy of Eastern Bushmanland earned N\$ 845,697 in direct income, which is 100% from hunting (Weaver & Skyer, 2003), and if 65% were distributed to members, this would amount to N\$ 1,374 (US\$ 196)/head of household assuming 400 households (Thoma, 2003b). The conservancy made only two cash payments, 1998 and 1999, to households (Berger, 2003), though additional payments are anticipated in the Weaver and Skyer (2003) analysis. Weaver and Skyer (2005 *In: Osofsky, Cleaveland, Karesh, Kock, Nyhus, Starr & Yang, 2005*) estimate a per capita income of US\$ 91 (N\$ 636) in 2002 if one includes hunting concession payments, salaries from professional hunting, handcraft sales and the value of meat consumed, though this is believed to be a gross estimate and not what is actually going to individuals and ultimately, heads of households. The conservancy provided more than 50% of the per capita livelihood benefits to the Nyae Nyae residents during 2003 (Weaver & Skyer, 2003).

The conservancy is also a major provider of jobs in all four districts of Nyae Nyae and by May 2002 employed five on the management committee, eight on the game translocation boma construction crew, ten on the technical water team and one on crafts, as well as people employed by the trophy hunter (eight full time, five half time), ten community rangers and one senior field officer (Berger, 2003).

If one converts the people employed by the safari operator, this would be equivalent to 10.5 people earning N\$ 35,660/year in employment (Berger, 2003) or N\$ 3,396 (about US\$ 485)/year/person.

In comparison, employment of the workforce in tourism from 16-65 years old ranged from 3.6% in the Kunene region to less than 1% in the Caprivi region. Average annual wages of those who received direct employment from tourism were very low; N\$ 6,000/person/year (\approx US\$ 1,000-500/year depending on exchange rate) employed in the Caprivi to N\$ 9,000/person/year (US\$ 1,500-750/year depending on exchange rate) in the Kunene region. The N\$ 9,000 wage was slightly higher than the average household income of N\$ 8,000, allowing the few who gained employment from tourism to significantly improve their lives by combining this income with traditional sources such as crops, livestock, pensions and remittances. However, for the average household, the benefits were not found to be significant (Long, 2004).

Nyae Nyae's wildlife and tourism potential could increase annual benefits several fold if wildlife populations continue growing, government recognizes wildlife and tourism as the predominant land use in the Nyae Nyae Conservancy and Nyae Nyae can produce and sell high value roan and buffalo populations to markets within the disease-free commercial production areas of Namibia and/or South Africa (Weaver & Skyer, 2003).

If the conservancy can develop the capacity to manage and use funds in an accountable and transparent way, Nyae Nyae could be the third communal area conservancy in Namibia to become self-reliant (Torra was the first, Uibasen the second) (Berger, 2003). A major problem that must be addressed is that conservancies in Namibia are legally accountable upwards to government but not downwards to their constituents, conservancy members (Long, 2004).

However, to date, payouts made by the conservancy have not made a substantial difference in meeting the basic needs of the majority of people in Nyae Nyae, particularly in fulfilling the most urgent need for food (Wiessner & /AiceN!aici, 2002 *In:* Berger, 2003). The conclusions in this report are based on weight data showing that in August 2000, people weighed significantly less than in 1978, which suggests that their nutritional status had declined. Cash does not immediately translate into food production. Distribution of cash dividends, if any, provides only a short-term solution to meeting basic needs. Longer-term strategies for using funds to generate more income and/or encourage food production are needed (Berger, 2003).

Often this cash is misused. The insidious influence of Tsumkwe town, with an increasing number of shebeens (bars), means that some young people drown their frustration in alcohol and so further reduce their potential for making a livelihood. The incidence of tuberculosis (TB) and alcoholism has taken a toll on conservancy staff (Berger, 2003). Thoma (2003b) is even more critical:

“The 600 inhabitants in Tsumkwe village are enjoying the service of not less than 53 Shebeens (drinking places offering mostly home-made beer). If one includes the approx 1,800 San inhabitants of the Nyae Nyae Conservancy in one’s statistic, then about 45 people (children included) are served per Shebeen. Often the San are offered drinks ‘for free’ and therefore become easily dependent on Shebeen/shop owners. In addition, the Tsumkwe Lodge offers more ‘fancy’ drinks to people earning salaries. And of course, one can easily imagine that the earned salaries are almost spent immediately. Based on this fact one needs to pose the question if any serious development is possible under such circumstances?...Also, the local priest is involved in buying crafts from the San but paying in kind (food or old clothes), which, of course does not educate the San in understanding the ins and outs of the cash economy. Often the San sell the food and clothes to be able to buy alcohol.

In my opinion the people drink because they are bored and try to forget their poverty, which indicates that the conservancy has not yet made a remarkable positive impact on the common San's life. I would like to stress that in my view the San are not alcoholics. If they would have the appropriate assistance in earning money from the conservancy they probably would invest it in income generating activities (own shop, craft production, etc), which would improve their lives, which again would be a reason to cut down on their drinking habits" (Thoma, 2003b).

Is it not also possible that they are caught between their traditional lifestyles and the Western world epitomized by the vices and materialism of Tsumkwe, thrown out of one world (hunter-gatherer), while being ill-prepared (lacking access to tertiary education) to cope with the new world (Western global) that confronts them? As will be presented in Chapter 11 (Section 11.11.6, Eco-genocide in Southeastern Cameroon [Division of Boumba-et-Ngoko], the Forest People and the "Dobi Dobi", More Parks and Protected Areas), one sees the same problem among the Baka Pygmies, dispossessed of their forests by parks and hunting blocks.

SCP, Tanzania

The number of people living in villages around the Selous Game Reserve (SGR) and benefiting from the Selous Conservation Program (SCP) is taken from the 1998 census and is therefore only an approximate figure (Kaggi, 2002):

- Total number of people 100,000;
- Total households 16,500;
- Number of participating villages is 57 out of 90 potential villages;
- Total "income from wildlife" is US\$ 41,327/year;
- Each village would get US\$ 725; and
- Each household would get US\$ 2.50/year.

There are four sources of the above income (Hahn & Kaggi, 2001 *In: Baldus, et al.*, 2001; Kaggi, 2002):

- Wildlife meat selling in respective villages
- Resident hunters from urban areas
- Voluntary contributions from hunting block owners operating trophy hunting
- Concession fee from photographic tour operator.

For social reasons, the bushmeat is sold to villagers at below market price. Additionally, some income by individuals occurs through logging and fishing in the pilot WMAs that generates fees paid into this fund (Baldus, *et al.*, 2003).

This “income from wildlife”, as described above, is from a meat quota given to pilot WMAs outside of the SGR, managed by communities (Hahn & Kaggi, 2001 *In: Baldus, et al.*, 2001). Village quotas are normally given by the Wildlife Division and hunted by village game scouts, villages being empowered to determine monthly harvests (Ngowe, 2004). This would appear to disallow hunting for cultural purposes such as by traditional hunters and/or by individuals who may have traditionally supported their families through the bushmeat trade.

In 1999/2000, this “income from wildlife” amounted to US\$ 46,001 (Hahn & Kaggi, 2001 *In: Baldus, et al.*, 2001) or US\$ 2.79/household. Of this, 56% was used by the villages for management and protection of the communities’ wildlife areas, 16% for village development and 28% kept in financial reserves savings. Though the income is very little, it is regarded by villagers, who are very poor with no assistance from government, to be very important. The meat hunting quota is the only sure source of meat protein, as sleeping sickness linked to the tsetse fly vector does not permit livestock of any consequence. The income is

mainly spent on community “common property” activities, schools, dispensaries, clean water, etc. Households do not see this money.

There is also the approximately US\$ 220,000/year from the “Selous 50% retention fund” destined for rural communities (see Section, 9.5.7, Selous Conservation Program (SCP), Tanzania). Like in CAMPFIRE, this income is mostly used for common property development (e.g., schools, clinics, boreholes, roads, etc.) (Hahn & Kaggi, 2001 *In: Baldus, et al., 2001*; Kibonde, *pers. comm.*).

Thus, this money does not go to heads of households.

Likewise, the 25% retention scheme, discussed in Section 9.5.3, Cullman Hurt Community Wildlife Project, Tanzania, ends up in the hands of local government – district councils - and rarely gets to the community, let alone individual heads of households (Hahn & Kaggi, 2001; Siege, 2001b both *In: Baldus, et al., 2001*). Between the 1992/1993 and 1999/2000 hunting seasons, this averaged US\$ 74,000/year (Hahn & Kaggi, 2001 *In: Baldus, et al., 2001*).

Therefore, in theory, this amounts to a total of US\$ 340,001²⁷¹/16,500 households in 2001 or US\$ 20.61/household, though the community only gets its hands directly on US\$ 15.84 - 16.12/household,²⁷² meaning that about 22% of the income from the SGR destined for communities and/or generated outside of the Selous Game Reserve (SGR) in community areas is not directly controlled by the communities. Like most of the CBNRM programs, even the US\$ 15.84-16.12/household money never really reaches the households.

Similarly, if equitably distributed, Igoe & Croucher (2006) estimate as currently managed that 45,000 people in the Burunge WMA of Southern Maasailand would

²⁷¹ US\$ 46,001 + US\$ 220,000 + US\$ 74,000

²⁷² (US\$ 41,327 + US\$ 220,000)/16,500 = 15.84 and (US\$ 46,001 + US\$ 220,000)/16,500 = 16.12

earn US\$ 5.20/person/year, or about US\$ 31/household per year, but in reality most of this income goes to common property benefits and not to households.

Therefore, household livelihoods do not see individual benefits and continue to “poach” natural resources to feed their families and pay school fees, as evidenced by the US\$ 750,000/year spent in anti-poaching out of the US\$ 2 million/year budget of the Selous Game Reserve (SGR) (Kibonde, *pers. comm.*) (see Section, 9.5.7, Selous Conservation Program, Tanzania). In the Selous,

“...as the villages still had not received formal land title, they did not have the authority to harvest the economically valuable resources of wildlife and timber on their lands. These are being used by outsiders – tourist hunters (safari operators) and pit sawyers who are sanctioned by the state. Most villagers depend on subsistence agriculture for their subsistence and cash needs, and in this context the village wildlands can impose negative impacts on the village. The incentives to conserve are not high enough compared with the costs, and there is not a strong motivation for collective action for the sustainable management of wildlife. The impacts on human/wildlife relations have to date been limited. The balance of costs and benefits has yet to tilt in the villagers' favor. Promoting collective action by rural communities can be difficult especially where community cohesion is weak. Socioeconomic status and political influence are two important divisions which can hamper fuller community participation at the level of the village grass-roots” (Gillingham, 1998 *In: Barrow, et al., 2000*).

If the “rules of the conservation game” were correct, little of the antipoaching money would be needed, since the local communities would be the “eyes and ears” of the Selous warden and his staff. In “their WMAs” community members would be policed by “effective community game guards”, respected by the resource users since they would be there not to stop the resource users but to collaborate with them to more effectively manage the resources as a means of improving rural livelihoods (households) and the prospects of their respective

entrepreneurs. A key problem with the 43 hunting and four eco-tourism blocks in the Selous is that for this to work, most of these hunting blocks and the wealth derived from them need to be operated by community-owned hunting/tourism companies in collaboration with SGR management or at least joint ventures with 50/50 net profit sharing.

This is easier said than done, but if ten to 15 years down the line this is not the goal, then the question is will the SGR survive the next 50 years and the projected doubling of human populations in Tanzania from 36.1 million in 2001 to 74 million by 2050 (PRB, 2004)? The SGR makes up 5% of Tanzania's territory, while 327,000 km² making up 30% of the territory is in some form of protected areas (national parks, game reserves, Ngorongoro Conservation Area (NCA), forest reserves, game controlled areas and not counting Open Areas with wildlife) (Maliti, 2003) or 374,494 km² (39.85% of territory) as defined by the IUCN (see Chapter 11, Section 11.10.6.3, Few success stories with the 10% factor). For these conservation areas to survive, the majority of benefits coming from these areas will need to go to peripheral communities and they must have a major role in the management and extraction of resources so that benefits significantly reach household levels. Otherwise, Tanzanians, who by 2005 have been compressed into 60-70% of the country causing major resource environmental degradation, have only one way to go – into the parks and reserves of Tanzania. Repression through anti-poaching is like the little Dutch boy with his thumb in the dike, a short-term stopgap that is not sustainable. Only it is not water but poverty and a mass of humanity which will inundate Tanzania's and Sub-Saharan Africa's parks and protected areas unless communities take pride and ownership over these areas as they do over their gardens, fruit trees and livestock, and then, as we will see, this is only part of the solution, as there are just too many people given the resource base, which is the fundamental problem (see Chapter 11, Section 11.10.6, Eco-

Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers)!

The meager amounts shared with local communities in the Selous program are not unique. It is estimated that in communities living around protected areas such as around the Ikorongo/Grumeti Game Reserves and Inkomo Open Area of the Serengeti in western Tanzania

“individual benefit sharing from the government generates an indirect US\$ 2.50/household/year, while wildlife related direct costs (e.g., wildlife crop losses – up to 33% of households lose 25% of annual harvest valued at US\$ 0.5 million) are US\$ 155/household/ year for communities living on the boundaries of the restricted areas” (Roe & Jack, 2001) or a net loss of US\$ 152.5/household/year from wildlife.

9.7.6.5 Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders

Speaking of the virtual destruction of one of the most vibrant wildlife ranching systems in the world since 2000, a U.S. National Park employee and former advisor to the Botswanan government had the following to say:

“for years we bragged that the wildlife institutions in Zimbabwe were biologically and economically sound. The problem is that they were not politically or socially (racially) sound. The institutions failed because they did not have sufficient involvement and sharing of wealth with black Africans. It will not end with Zimbabwe. The president of Namibia has praised the land redistribution that has occurred in Zimbabwe, and he has hosted teams of Zimbabweans who briefed him on the procedures that were used in Zimbabwe. The horrendous rate of murders in South Africa suggests that the situation there is not sustainable” (Cacek, 2004).

The inequality that exists between Sub-Saharan Africa's safari industry, mostly run by expatriates and/or whites, can be summed up by a comparison given by Baldus and Cauldwell (2004) for areas around the Selous Game Reserve (SGR), Tanzania. The average person works for TZ\$ 600/day, the equivalent of US\$ 0.50-0.60/day. The average daily rate for overseas hunters is US\$ 1,500/day or the equivalent of about six years of local labor working seven days/week (Baldus & Cauldwell, 2004). Watkin (2003) warns of jealousy from uneven benefit sharing between partners as a threat to sustainability in the development of East African community ecotourism. Such inequalities make it difficult for local people to buy into conservation and can only be overcome with a combination of appropriate policies linked to land and resource tenure giving communities ownership over their resources, along with local people knowing the value of resources so that they can negotiate a rightful share of value from harvested resources. Though controversial, one has to ask if analysts such as Patel (1998 *In:* Hasler, 1999) are not too far off in concluding that many of the CBNRM and hunting programs keep rural communities marginalized while maintaining the old colonial ties between the safari operators and governments. As late as August 2005 in the new South Africa, rural black communities in a presentation to the Ministry of Environment and Tourism had the following to say concerning the safari industry,

“this industry is an ‘old boys club’ of white men who keep the clients and their networks to themselves for financial gain. The standards and requirements set for one to become a professional hunter, which you need before being registered as an outfitter, or before you can become the director of a hunting academy, are stacked against black individuals” (RSA Community Organizations, 2005).

One of the most difficult problems in CBNRM is obtaining accurate figures from any private sector operator on the cost of doing business, net profits and distribution of these profits. During the period the principal author worked for the

sport hunting organization Safari Club International, from 1995-2001, technical staff failed at getting safari operators to share details on cash flow in the safari industry. The following is gleaned from a proposal put together by the principal author in collaboration with Franz Wengert in a business plan to the Uganda Wildlife Authority (UWA) in early 2002. This was undertaken under the name of Uganda Windrose Safaris (UWS), a registered company for which the principal author is a shareholder, but which has never operated in Uganda, as the proposal was rejected. The major reasons for this rejection are highlighted in Chapter 11, Section 11.7.3.2, Eco-welfare Uganda, 2002. The proposal called for taking over the management of the Semliki, Bugungu, Karuma and Pian-Upe Game Reserves. The other key investor, Franz Wengert, is a retired millionaire of Wengert Windrose Safaris, Tanzania. These figures are extremely accurate as they are the hidden figures calculated by the principal author in collaboration with Franz Wengert as a means of developing a company. They are believed to be reflective of a typical safari operation over much of Sub-Saharan Africa and lay bare the realities of this very secretive industry. The start-up costs were estimated at:

<u>Item</u>	<u>Start-Up Costs (US\$)</u>
House/Compound	100,000
Equipment For Compound	10,000
Boat and Engine	15,000
Four Equipped Camps	60,000
Unimog Truck	25,000
Tractor	25,000
Vehicles	100,000
Office Equipment	10,000
Register Company	2,000
Consulting Fees	4,500
Other Start-Up Costs	5,000
Marketing	20,000
Subtotal	376,500

An additional **US\$ 50,000** would be reinvested each year thereafter. This is similar to the start-up costs of US\$ 322,000 given by Mayaka (2002) for hunting in Northern Cameroon and US\$ 350,000 in Tanzania (Hurt & Ravn, 2000 *In:*

Mayaka, 2002). One could of course start smaller and build up slowly. Because Wengert had an excellent client base, the idea was to initially use clients' money the first year or two to cover the start-up costs.

Most of the fees below were those used in Tanzania (prior to the new fee structure of 2007, where more income will go to government, see Section 9.6.3.6, SCP, Tanzania) and recommended for adoption to the UWA. This is based on a recommended quota among 34 species, the key 21 key species being:

Recommended Hunting Quota Number	Trophy Fees (Official/Company US\$)	Total Value + 20% Community Surcharge on Trophy Fee (US\$)
35 Buffalo	500/750	31,500
6 Lion	1,000/2,000	14,400
6 Leopard	1,000/2,000	14,400
15 Hippo	500/800	14,400
4 Greater Kudu	600/1,200	5,760
6 Lesser Kudu	750/1,400	10,080
12 Sitatunga	1,000/1,500	21,600
70 Uganda Kob	300/470	39,480
18 Bushbuck	200/400	8,640
14 Jackson Hartebeest	300/480	8,064
8 Zebra	250/450	4,320
24 Defassa Waterbuck	300/480	13,824
12 Bohor Reedbuck	150/300	4,320
9 Giant Forest Hog	750/1200	12,960
18 Bushpig	100/300	6,480
4 Oryx	600/1,000	4,800
12 Oribi	100/240	3,456
2 Roan	600/1,200	2,880
10 Topi	250/250	5,400
10 Crocodile	450/700	8,400
2 Giraffe	750/1,500	3,600
Subtotal	-	238,764
Other Species	-	48,888
Grand Total Trophy Fee Value	-	287,652
Source: Principal Author		

The two trophy fees are 1) what was recommended to government and then 2) what the client would be charged, the difference going as part of the gross profits to the company. Additionally, a 20% surcharge to the client on all trophy fees was proposed to be used for community development. These and the other minor species would be used to conduct:

CATEGORY OF HUNT	TOTAL VALUE, DAILY RATE (US\$)
20 Buffalo 7-day hunts @ US\$ 1,100/day	154,000
Five 21-Day Hunts @ US\$ 1,200/day	126,000
Ten 12-Day Mixed Bag Hunts, @ US\$ 1,200/day	144,000
200 Days non-Hunters @ US\$ 200/day	40,000
Total Daily Rate Value	464,000
Grand Total, Trophy Fees + Daily Rate	751,652
Other Charges To Client (Gun Licenses Dipping/Packing, Transport)	66,750
GRAND GRAND TOTAL FROM HUNTING CLIENTS (Trophy Fees + Daily Rates + Other Charges)	818,402
Source: Principal Author	

It should be noted that it is likely that not all of the annual trophy quota would be used, but this would affect government more than the safari company as it would make the majority of its income from the daily rate. The distribution of income is indicated in Table 9.12.

This is believed to be about as realistic as one can hope on how income is distributed. The percentage of net profits after recurring costs to the company are factored out is:

- 47% for the company
- 39% for the government, and
- 14 % for the communities

Table 9.12: Distribution of income from safari hunting with outside safari company managing hunting block

COSTS AND BENEFITS	US\$	% OF NET PROFITS
GROSS	818,402	
Government Portion of Trophy Fee	138,000	
Gun Licenses	6,000	
Dipping Packing and Export Fees	8,500	
Hunting Licenses	22,750	
Block Fees (4 Blocks)	20,000	
Professional Hunters Licenses (5)	10,000	
Work Permits (5)	2,500	
Company License	2,000	
NET INCOME TO GOVERNMENT (UWA)	209,750	39 (25.6% of Gross Turnover)
Remaining to Company	608,652	
RECURRING COSTS		
PH DAILY RATE US\$ 150/HUNTING DAY, 360 DAYS	54,000	
CAR RATE TO PH US\$ 70/HUNTING DAY, 300 DAYS	21,000	
PH TRAVEL DAY US\$ 40/TRAVEL DAY	2,800	
SALARY 2 NON HUNT PROF, US\$ 100/DAY	40,824	
Salary CEO	20,000	
COMPANY RUNNING COSTS (Elec., FUEL)	100,000	
MARKETING	20,000	
Dipping Packing Fees	14,500	
Subtotal	273,124	
Net To Company	335,528	
COMMUNITY BENEFITS		
GENERAL STAFF	15,000	
OFF SEASON ANTI-POACHING (4 Months)	15,000	
20% Of Total Trophy Fee (Govt. + Company)	47,942	
NET INCOME TO COMMUNITY	77,942	14 (9.5% of Gross Turnover, 5.9% if salaries discounted)
NET PROFIT TO COMPANY	257,586	47 (Gross Profit Margin 32%)
TOTAL NET PROFIT	545,278	

Source: Principal Author

The company's profit is after paying the owners their salaries and covering operational costs so in essence, this is "money in the bank" for the company's owners.

It was recommended that 25% of the government benefits be given to the rural communities, which would have resulted in company benefits remaining the same while net profits to other stakeholders would be:

- 29% for government; and
- 24% for the communities

The actual proposal showed only US\$ 27,000 going to the community from the 20% community surcharge on the trophy fee, so that only about 10% of the net profits would accrue to the rural communities, while the company's percentage would jump to about 50% of the net profits and the government's would remain at 40%. These are the kinds of games played by the private sector to maximize their profits. If the stakeholders are not clearly aware of the costs and the benefits and capable of negotiating an equitable share of the profits, a good capitalist will take advantage of them. Basically, most of the information provided in this section is a "black box" to everyone but the safari operator, giving him/her the comparative/competitive advantage in assuring that he/she obtains significant benefits from this venture.

The gross profit margin²⁷³ to the hypothetical company in Table 5.11 is estimated at 32%. Using data from Lamprey, Buhanga and Omoding (2003), the percentage of profit to a safari company after payment of government fees in the Ugalla East hunting block of western Tanzania in 1992 was 56%. This does not account for

²⁷³ (Net Profit To Company/Gross Profit) x 100 = 257,586/818,402 = 32%

company operational costs, marketing, paying PHs, etc. If the hypothetical company operational and marketing costs are added to the net profit shown in Table 9.12, a similar figure of 65% of the gross turnover is derived, indicating that the gross profit margin should be in the same ball park for the Ugalla block if operational costs are considered. With the data given by Lamprey, *et al.* (2003), running costs are not provided; therefore the gross profit margin cannot be determined.

Communities receive much less than the 25% net profits compared to the other two stakeholders as calculated by Mayaka (2002) for Cameroon, while the gross profit margin to the safari company is higher than the 20-25% gross profit margin suggested by Hurt and Ravn (2000 *In:* Mayaka, 2002), but not too different. De la Harpe, *et al.* (2004 *In:* Child, B., 2004a) give a rule of thumb recommendation for communities/landholders to negotiate 33% of the turnover (gross) from hunting and 10% of the turnover from tourism. In the case above, the community is receiving only 9.5% of the turnover and only 5.9% for community development if salaries are excluded (Table 9.11).²⁷⁴ Child, Castley *et al.* (2004 *In:* Child, B., 2004a) recommend that the producer community captures 33-40% of the outfitters turnover from safari hunting. However, Khumalo (2005) estimates that CAMPFIRE communities capture only 10% of the gross turnover from safari hunting, similar to that in Table 9.12, but does not separate out income from hunting on private and state lands versus CAMPFIRE areas that could significantly increase the actual gross profit margin to the community. In 2001, 9% of the turnover to the community could be calculated from both consumptive and non-consumptive tourism in the Kunene, Erongo and Caprivi regions (Long, 2004).²⁷⁵ Based on analysis of ADMADE data from 1992 (DeGeorges, 1992a), a gross profit margin to the safari operator is obtained of from 14-19% respectively

²⁷⁴ (US\$ 77,942/US\$ 818,402) x 100 = 9.5% of gross turnover to community

²⁷⁵ (US\$ 833,333 to communities/US\$ 9,416,666) x 100 = 9%

for Grade B²⁷⁶ and Grade A²⁷⁷ hunting blocks, while the community received on average 3.7-4.4% of the gross turnover of which 1.7-2.0% of this went directly for community development (see Section 9.5.2, ADMADE, Zambia and associated footnotes).

The above figures may vary as to the exact trophy fee. Some safari companies retain the government trophy fee in their advertisements while upping the daily rate to make their profit. It is a matter of marketing strategy (e.g., drawing people in with a relatively low daily rate and catching them on the trophy fee). The safari industry is very competitive and within a limited range, there is room for manipulating the price structure. Certainly, the price charged to the hunting client is not purely about trophy quality, which can be excellent on fenced game ranches. The top daily rates in Africa come from those countries in Africa (e.g., Tanzania, Botswana, Zambia, Cameroon, RCA) that can still provide the experience of “Wild Africa” to their clients: large free ranging areas, where one can as easily bump into a lion and elephant as a kudu and at night can listen to the lions roaring and the hyenas cackling.

It is believed that benefit distribution to stakeholders from tourism is similar. In the case of Maasai Mara, Kenya, what appears to be gross turnover to the surrounding communities from eco-tourism in 1988 amounts to only 1% to the Maasai and 10% to local government (Narok Council). Likewise, only 1% of gross turnover from the Amboseli National Park in 1990 went to the peripheral Maasai communities, amounting to US\$ 150,000 out of US\$ 15 million of wildlife revenues (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure

²⁷⁶ Gross profit margin from Grade B hunting block to safari operator = [(US\$ 145/day to safari operator after expenses x 168 days = 24,360)/US\$ 177,600 Gross Profits) x 100] = 14% gross profit margin to safari operator in ADMADE, Zambia.

²⁷⁷ Gross profit margin from Grade A hunting block to safari operator = [(US\$ 230/day to safari operator after expenses x 252 Days) = US\$ 57,960/US\$ 309,600 Gross Profit] x 100 = 19% gross profit margin to safari operator in ADMADE, Zambia.

and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya).

Anyway, it looks as if today, in 2007, the income from hunting and tourism to communities is skewed and, as shown, is insignificant. This becomes most evident at the household level.

Unfortunately, even where countries are Africanizing the safari industries, as discussed, most African safari operators do not come from or represent the communities, but come out of the already politically connected private sector or bureaucratic elite patronage system. Both use their connections to obtain safari concessions and exhibit a behavior no different from the expatriate safari operators in their relationship with rural communities and the sharing of wealth from their resources. In other words, to local communities they are as much foreign interlopers as a Frenchman or German safari operator exploiting the communities' resources; "white black men".

Magome and Fabricius (2004 *In: Fabricius, et al., 2004*) state that "if the bulk of benefits from biodiversity conservation accrue to outsiders (that is, someone else benefits from the efforts of local people), then other strategies need to be adopted to conserve the resource in question". As noted in Table 9.12, most of the jobs for Africans in the safari industry are low paying (skimmers, trackers, tent boys, cooks, etc.), amounting to US\$ 15,000/year distributed between 50 full and 50 part time employees, while five expatriate staff would split US\$ 135,824 plus profits. The disparity is evident.

A major problem with most CBNRM programs is that management contracts with communities have had little to do with management, wildlife monitoring or running the business. They are "laborers and landlords", which results in passive

participation and strong disincentives to work (Boggs, 2004 *In: Fabricius, et al.*, 2004), since community benefits are given for being “observers on the sidelines” rather than players on the field; a form of welfare where you are given money for waking up in the morning. Jones and Murphree (2004 *In: Child, B.*, 2004a) conclude that in most CBNRM areas of Botswana and Zambia, communities tend to be passive recipients of benefits from wildlife without engaging in active management.

The authors believe that this is an endemic problem across CBNRM in Sub-Saharan Africa and has much to do with the government’s unwillingness to give up control over power and potential wealth to communities from full land and resource devolution. In other words, there is little or no motivation by rural communities/resource users to accept or buy into Western ideas of conservation if both the economic (e.g., low benefits/household and/or little or no distribution to households, plus only menial labor jobs) and cultural benefits are negligible and they feel little or no ownership over the business or the resources that consequently become insignificant in their daily lives. Common property theory argues that rural communities and resource users must be empowered to make decisions, enforce rules and actively own resource-related businesses (Ostrom, 1990 *In: Boggs, 2004 In: Fabricius, et al.*, 2004). This is rarely the case to date.

Capitalism will not hand the communities their supper. In order for change to take place and for communities to take control, they must understand the costs and benefits to the industries operating on their lands, be they safari hunting, photo safaris, mining or logging companies.

Unfortunately, governments and the private sector are taking the “lion’s share” of the profits that should accrue to the rural communities. This is happening because of antiquated laws over land and resource tenure and ignorance on behalf of the

communities. As is discussed under the Dozo case study in Burkina Faso (Section 9.8.9.1, Management of the Comé-Leraba Game Reserve, southern Burkina Faso) and the White Mountain Apache case study (Section 9.9, WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM), at a minimum, the trophy fees should go to the community. The government's taking of the trophy fee is like taking the value of each cow on a man's land; why would he want to keep cows or, in this case, wildlife (see Section, 9.7.6.2, Stop taxing the full value of the community's wildlife)? The government should be happy with the hunting license, gun license and dipping/packing and company license fees, work permits, as well as annual company and personnel taxes. Block fees should go to the community to cover the costs of managing the area.

As community members become better trained, ideally, they should form a not-for-profit safari company and then the lion's share of the profit, including the daily rate and trophy fee, should go to the community or community shareholders (Table 9.13).

Bond, *et al.* (2004 *In: Child, B.* 2004a) call it a “village company”. They go on to explain that both trophy hunting and photographic tourism are luxury products with a high-income elasticity, meaning that they are sensitive to global economies and incomes and national/regional/global political instability. This implies that some diversity (e.g., catering for both overseas and local tourists and hunters, diversifying into adventure tourism, sport fishing and cultural tourism) can help a company weather hard times such as a global economic downturn, a locally strong currency as South Africa was experiencing in 2004/5 or threats from terrorism that discourage international travel. De la Harpe, *et al.* (2004 *In: Child, B.,* 2004a) argue that the commercialization of resources in protected areas, be it tourism or hunting, have minimal risks and tend to be self-controlling if “high-value goods” such as trophy hunting and luxury up-market tourism are the driving

economic engines, compared to high risk “low-value bulk commodities” such as mass tourism and game meat production.

Table 9.13: Distribution of income from safari hunting with community-owned safari company and trophy fees going to land owners

COSTS AND BENEFITS	US\$	% OF NET PROFITS
GROSS	818,402	
Gun Licenses	6,000	
Hunting Licenses	22,750	
Dipping Packing and Export Fees	8,500	
Block Fees (4 Blocks)	20,000	
Professional Hunters Licenses (5)	10,000	
Work Permits (5)	2,500	
Company License	2,000	
NET INCOME TO GOVERNMENT (UWA)	71,750	14
Remaining to Community Safari Company	746,652	
RECURRING COSTS		
PH DAILY RATE US\$ 150/HUNTING DAY, 360 DAYS	54,000	
CAR RATE TO PH US\$ 70/HUNTING DAY, 300 DAYS	21,000	
PH TRAVEL DAY US\$ 40/TRAVEL DAY	2,800	
SALARY 2 NON HUNT PROF, US\$ 100/DAY	40,824	
Salary CEO	20,000	
COMPANY RUNNING COSTS (Elec., Fuel)	100,000	
MARKETING	20,000

OFF SEASON ANTI-POACHING (4 Months)	15,000	
Dipping Packing Fees	14,500	
Subtotal	303,124	
Net to Company	443,528	
NET PROFIT TO COMMUNITY AFTER EXPENSES		
[Gross-(Government Fees + Recurring Costs)]	443,528	86
TOTAL NET PROFITS (UWA + COMMUNITY + SAFARI COMPANY)	515,278	100

Source: Principal Author

With a community-owned company plus keeping trophy fees, net profit distribution is radically changed:

- 14% of the profits after operational expenses go to government
- 86% goes to the community

The amount of US\$ 443,528 versus US\$ 77,942 is a 5.7-fold increase in income to the community.

If necessary, they can hire professional hunters until they get people from the community trained up. Unfortunately, unless human populations are low relative to the resource base, this still may not make a significant economic dent at the level of the household and still argues for allowing the community a diverse use of the resources from the hunting block as long as the off-take is controlled and sustainable based on land use planning (see Section 9.10, WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM). To be successful, this will also require conservation to fit into a larger plan to urbanize and industrialize the continent, taking pressure off the resource base, as discussed in a number of places throughout this book. This could be in addition to allowing controlled meat hunting, charcoal making, logging, fishing, honey/wild food, wild medicine, maybe some grazing of livestock, etc. to maximize household income.

To derive the above revenues means that well-trained people in marketing, safari operations and professional hunting from the communities will be required. Ideally, some community members will be trained at the tertiary (university) level in wildlife/habitat management as discussed in Section 9.7.5, Lack of Technical and Management Skills. To charge these prices, they must be able to meet certain standards of accommodation, transport, cuisine and overall experience. It will not

be easy, but Cacek (2004) gives ample examples of successful African safari operators to indicate that this change can and must happen if wildlife and safari hunting are to survive the 21st century intact. At a recent meeting between the principal author, John Jackson of Conservation Force and George Pangeti, current deputy director of the Zimbabwe Parks Board and former deputy director of Wildlife, who also serves as a technical consultant to Safari Club International, Pangeti (*pers. comm.*) stated that the overseas sport hunters had better get used to hunting with black professional hunters and safari operators – that is the wave of the future.

Later in this chapter, community run *chasse libre*/self-guided hunts in Burkina Faso are discussed as possible models (see Section, 9.8.9, *Gestion des Terroirs*, West Africa) (Figure 9.2). The sport hunter is guided by a traditional hunter. The income in *chasse libre* is much lower due to reduced daily rates and salaries since the communities are currently unsophisticated and are unable to provide the services of luxury safaris usually provided by expatriate white operators (Tables 9.14 and 9.15). If they undertook a joint venture with a “great white hunter”, he would keep the daily rate and thus their earnings would not be much different, possibly even less. On the other hand, in a *chasse libre* program, the community has little or no overhead, since the client furnishes/rents all materials from vehicle to camping gear to food, even salt – the lower daily rate is money in the bank for the community. This is a market niche with much potential, allowing communities to enter into a safari operation with minimal capital. In Burkina Faso, the communities make most of their money on the trophy fees. Thus, this mandates trophy fees going to communities, as a minimum, if *chasse libre* programs are to be economically viable.

Table 9.14: *Chasse libre* costs Burkina Faso, direct costs going to community and government

COST	CFA	US\$ or EURO	Jobs	CFA 14 DAY	US\$ 14 DAY	CFA 9 PLAINS	US\$ 9 PLAINS

NOTE: Cost To Hunter Greatly Reduced If 2 People Hunt Together, Cut Out Translator, Vehicle Only Picks You Up And Drops You Off, Etc - These Are Maximum Costs. At time of this analysis, US\$ and Euro at the same exchange rate 650 CFA, in late 2005 exchange is Euro 650/CFA and about US\$ 550/CFA. Apples to Tables 9.14 and 9.15						
Source: Raw Data Provided By Jean Michel Pavé, World Bank, Abidjan, Cote d'Ivoire and Morgane Echappé in Burkina. Table constructed by principal author						

Thus a *chasse libre* hunter in 2005 paid US\$ 7,475 all inclusive, including plane ticket, vehicle rental, food, daily rates and trophy fees for a buffalo and a roan antelope on a 14-day buffalo hunt. The community earned US\$ 2,565 (34%) of the gross, including employment (more if the plane ticket is not counted) from this total in daily rates and employment, while the government earned US\$ 376 in various fees. An all-inclusive ten-day antelope hunt cost the hunter US\$ 6,143, assuming two trophies, a roan and sing-sing waterbuck. The community earned

US\$ 1,810 (33%) of the gross, including employment (more if the plane ticket is not counted), while US\$ 376 goes to the government.²⁷⁸

In addition, what a community gains from the *chasse libre* program, which does not happen under a joint venture with an outside safari operator, is the pride and dignity of running their own operation, which is not dissimilar to the White Mountain Apache hunting scheme.

As these communities become more sophisticated and offer more services (e.g., provide their own vehicle, food and camping gear), they can up their daily rates and salaries and start marketing to a higher paying clientele. For instance, the White Mountain Apaches offer their clients luxury lodges, food and ground transport, as well as the top elk trophies in North America and can thus afford to charge US\$ 15,000 dollars for about a five-day hunt. In addition, there is a three-year waiting period. Thus, quality of services and uniqueness of trophy/experience in a market-economy dictates how much one can charge (see Section 9.9, WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM). A major constraint will be overcoming the myth of the “great white hunter” that to this day is romanticized in hunting books in favor of the “great black hunter”. This attitudinal change will take time, but quality trophies and good experiences will change attitudes.

Chasse libre prices are indicative of just how far many African rural communities have to go to be able to maximize profits from wildlife based on improved marketing and services. However, uniqueness such as a bow hunter hunting with Bushmen or being guided by traditional Dozo hunters and 14 day classical foot

²⁷⁸ Note: This is based upon 2003 data. In 2007, a 14 day buffalo hunt will cost Euro 4,500 + 890 Euro in trophy fees if a buffalo and roan antelope are taken; Euro 5,390 in total (US\$ 7,258). A 10 day antelope hunt will cost Euro 3,500 + 830 Euro in trophy fees for a roan and waterbuck; Euro 4,330 in total (US\$ 5831). This does not include costs of airline, hotel before and after, tips, alcohol or trophy shipment (DeGeorges, 2007).

safaris with Pygmy hunters have the potential to be marketed as both a hunting and cultural experience for which the hunter should be willing to pay dearly. Currently, this is not the case.

Communities wishing to start their own business can cut down significantly on the start-up costs. Camps can be made inexpensively out of local materials with local labor. One of the nicest camps the principal author has seen was a camp that was virtually an “African village” belonging to the famous but late French safari operator, Jacques Guinn. There were no generators, only paraffin lamps and refrigerators. The woven mat compounds in Zambia and Burkina Faso’s Comé-Leraba Reserve hunting camps are other examples, though they must be rebuilt yearly. Another way of decreasing start-up expenses is by hiring professional hunters who come with their own vehicles, the reason for car rates in Tables 9.12 and 9.13 is to reimburse the professional hunter for wear and tear on his vehicle. Thus, the community safari company should be able to initially get by on one vehicle and slowly build up as net profits are reinvested into the safari operation. Finally, a compound need not cost US\$ 100,000 (cost estimated for a compound in Entebbe, which would have served as an office, living quarters, supply storage and garage), especially if built locally by the community. However, someone in an urban center will need access to the Internet to communicate with clients, handle inquiries on a daily basis and be available to help clients through customs.

Another option to avoid the reduced income from *chasse libre* is for a community to negotiate with a safari operator/mentor to joint venture with a built-in requirement for on-the-job training so that after ten to 15 years, the community can be running most of the operations themselves, gaining the benefit of an increased daily rate. In addition, to sending off selected community members for tertiary training in nature conservation, hotel management, catering, marketing, business, accounting, etc., be it in safari hunting and/or tourism, any joint venture

initiative that will surely be with an “outside of the community area” private sector partner, should consider the following within the contract:

- The majority of the employment goes to the community.
- Purchasing as much locally produced materials (e.g., vegetables) as possible.
- Community members will be trained in skill positions initially filled by outsiders through on-the-job training (professional hunters and guides, camp managers, cooks, drivers, etc.).
- Tertiary training scholarships will be provided for certain skill positions as noted, with general scholarships provided so that youth can fit into a global society, most likely in urban centers.
- A 15-20 year horizon should be provided for, in which the lodge or safari operation becomes community-owned.
- Some youth on returning from their studies and/or traditional hunters from the community will be apprenticed as professional hunters.
- Key people from the community will be trained in company management and exposed to the overseas market such as the SCI and Dallas Safari Club conventions. Developing links to the market place and overcoming dependency on a middleman may be the most important aspect of this learning experience. Without it, be it in wildlife, general tourism, timber, minerals, agricultural produce, etc. Sub-Saharan Africa will always be dependent upon the middleman who will take the majority of the profits.
- This also holds for adopting technologies of transformation, such as taxidermy, as a means of beneficiation (added value) from the resources. For instance in South Africa the added value of taxidermy is between US\$ 10-28 million/year (See Chapter 5, Section 5.12.7, Attaining Food Security through More Appropriate Land Use Options, Wildlife as a Land Use Option on Marginal Lands).
- Client lists will be gradually transferred over to the eventual community-owned company.

One problem with this, as summed up by Emerton and Mfunda (1999 *In: Roe & Jack, 2001*), is that

“private sector initiatives such as direct payment of fees for land use, the promotion of wildlife related markets, and the development of joint management projects do have the potential for increasing the local value of wildlife, although they do not compensate for opportunity costs. However, these initiatives may simply be replacing the existing top-down governmental model of

conservation, and unless they directly increase landowners' control over the management of their own resources, local communities will remain dependent on these external agencies”.

This comes back to the best option of communities starting their own companies. The “community-owned company” would hire white professional hunters to hunt and market, and to apprentice local community members in professional hunting, while taking them marketing in America and Europe. The community in the meantime would still retain ownership of the company and thus the majority of net profits as reflected in Table 9.13. In such cases, involving an older semi-retired safari operator/professional hunter as a “mentor” might be the way to go. This latter option permits the community to retain the lucrative daily rate! They could also use a booking agent, who will take about 15% of their daily rate, to find clients, but then must have the other skills and sophistications, many of which are lacking today, but which can be acquired through experience and on-the-job-training with a mentor. This same concept is being used to get subsistence farmers into commercial farming in South Africa (see Chapter 5, Section 5.12.6.1, South Africa, an emerging model in public private partnerships).

Once again, the community must clearly understand the costs and benefits and assure itself an equitable share of the net profits. Right now, this is not the case. Jones and Murphree (2004 *In: Child, B., 2004a*) describe this as an imbalance of power in negotiations between communities and the private sector, which has capital, knowledge of the industry and implementation expertise such as marketing, client rapport, camp development, etc. Unless the community is wide awake, the risk is that they will be taken advantage of by the private sector with regards to equity in revenue sharing or even in over-harvesting wildlife resources for short-term gain.

In certain cases, the use of tendering/auctioning has been tried to “force” the private sector to maximize its share of the profits (e.g., CAMPFIRE in Zimbabwe, Botswana Community Trust Program and ADMADE in Zambia). Better, however, is to clearly understand the bottom line net profits and to be prepared to sit down at the negotiating table with the safari operator of choice, someone a community feels comfortable with, in order to “cut a deal”. There are a number of instances where unscrupulous operators have overbid, giving a larger share of the profit to the other stakeholders than makes economic sense, in order to obtain a hunting area and then over-shoot the blocks to get their profit out. Regardless, the community will have to be trained in monitoring the wildlife and habitat in its hunting block, while monitoring the off-take to assure that its resources are not being abused and that wildlife utilization is sustainable both economically and ecologically. Once again, this spells out the crying need for tertiary education for selected members from the community to return and manage these businesses. There is also a need for a mentoring program.

All of this takes time and time is running out for Sub-Saharan Africa, its people and their wildlife.

9.7.7 Inappropriate or no Wildlife Monitoring to Assure Sustainability

“In the absence of reliable ecological data, cumulative experience of setting quotas over many years relying on a number of indicators (e.g., trophy quality) provide the basis for an adaptive management approach” (World Bank, 2005).

While “adaptive management” is believed to be the only hope for the long-term conservation of wildlife by getting added value for wildlife from international tourists and hunters, one of the shortcomings is the perceived failure of governments to maintain or establish long-term cost effective wildlife monitoring

programs to assure that the off-take is economically and ecologically sustainable, both in and out of CBNRM areas.

Most wildlife monitoring programs in Africa have been dominated by Western researchers and scientists without concern for cost, being propped up by donors, and with little or no understanding for the kind of biological and physical data needed to make decisions about hunting quotas and other interventions. Very often, expensive aerial surveys are employed with high standard errors, making the information useless for making management decisions. Techniques such as aerial “distance sampling” every third year (if money were available, which tends not to be the case unless a donor is funding the effort, and then this is not sustainable since in time the donor will tire and leave), with on-the-ground monitoring by professional hunters, rural communities and wildlife department officials are believed to be more cost effective, while providing useful information to make informed management decisions (DeGeorges & Reilly, 2002). It is highly questionable as to whether total numbers are needed for trophy hunting.

“It is clearly not feasible to accurately estimate populations for all hunting areas. It is doubtful that a truly scientific basis for setting quota will ever be developed in the complex-multi-species ecosystems in Africa. Instead the cumulative experience of setting quotas over many years that relies on several verifiable indicators (population estimates, trophy quality, age, off-take levels, etc.) that can demonstrate little or no significant detrimental impacts on the wildlife populations provides the bench mark that allows for the confidence of setting hunting quota through an adaptive management approach...Maintaining adequate trophy quality from a population over a period of time is sufficient evidence that the population is not being over-hunted” (Baldus & Cauldwell, 2004).

Thus, additional data, if money is available, may improve decision-making, but at a minimum, trophy quality trends over time should be mandatory for any trophy hunting program in Sub-Saharan Africa (von Brandis, 2004).

However, if in the future meat hunting is desired, having some ideas of total numbers for those species to be harvested for meat would be desirable. In addition, periodic population estimates of charismatic species such as lion, leopard and elephant may be needed to fight international political battles or to meet international requirements such as at CITES (see Chapter 10), where the animal rights groups attempt to use misinformation to shut down hunting, believing it to be immoral. Due to their cryptic nature and the cost if not impossibility of obtaining total counts, figures on national and regional lion and leopard populations will always be educated guesses based on best available data and put together by experts, not total counts, as seen in the latest attempt to describe lion populations in Sub-Saharan Africa (Chardonnet, 2002) (see Chapter 10, Section 10.8.2.1, Status of African lion, Vulnerable [VU A2abcd], Except Regional Population of West African). Indices such as nose pigmentation, teeth, facial markings, leg markings, size and mane development at harvest (Whitman, 2002; Whitman & Packer, 2006) as well as skull measurements (DeGeorges & Reilly, 2002), tooth aging (DeGeorges & Reilly, 2002; Cheater, Thesis in preparation) and carcass length and weight after harvest may be used to determine whether the lion is/was of a harvestable age (DeGeorges & Reilly, 2002). Similar indices could be developed and would apply to leopards.

Hulme and Taylor (2000 *In:* Lee & Kirkpatrick, 2000) explain that worldwide, wildlife biologists have yet to achieve the goal of knowing the total population size by species. They explain that aerial surveys, in addition to being expensive, are generally effective for large dark-bodied herbivores such as elephant, buffalo and sable, but inefficient for most smaller-bodied antelope in wooded savannas where sampling and observer biases are particularly problematic. They

recommend adapting wildlife monitoring to local conditions through the collection of indices as opposed to trying for total game counts. They state that 1) rural communities have in depth knowledge about wildlife, 2) census must be a means to an end, the establishment of a sustainable high-quality trophy off-take for the lucrative market, 3) the goal should not be trying to get total numbers but trends/indices (population increasing, stable or decreasing; trophy quality; hunter effort “catch-per-unit of effort” – how many days to harvest each key trophy; hunter success – did hunter succeed or not in getting key trophies; herd structure, size and movements, recruitment, degree and location of encroachment such as poaching, livestock, small farmers, etc.) while keeping a constant error, 4) methods that require highly accurate measurements, sophisticated technology and complicated analyses should be avoided and are likely not sustainable, 5) annual counts, random walks by game guards and fixed transects provide an index of population abundance, where accuracy is less important, but precision with a high level of repeatability with a constant error is critical and 6) observations per time as opposed to distance may be easier to measure unless a vehicle or GPS is employed. They found that when compared, in the same area, random walk sample counts and transect counts showed little or no difference. Further discussion on the issue of total counts is provided in Chapter 10, Section 10.7.2.2, “Enhancement as a requirement. Why it was inappropriate in 1993 and still is so in 2002”. This section deals with the fact that total elephant counts (e.g., population estimates with high standard deviations/errors) were required before allowing hunted trophies into the United States.

Hulme and Taylor (2000 *In:* Lee & Kirkpatrick, 2000) explain that while biologists tend to stratify and systematically count across ecological gradients to count game, local residents go directly to the areas where they know the game occurs. Game guards can be used to collect such information, along with sport and professional hunters. Parker (2004) is a strong proponent of using local knowledge to estimate wildlife status. Speaking of Jonathan Kingdon’s

compilation of data on East African fauna using traditional hunters, among others, Parker (2004) states

“living among the animals, they knew infinitely more about local distributions than did transient white research boffins”,

who would most likely have been expatriates in East Africa as opposed to Southern Africa. The wildlife biologist/anthropologist Marks has been using success rates versus time and distance from village by traditional hunters for years as indices of wildlife abundance in the Munyamadzi Corridor, Luangwa Valley, Zambia (Marks 1994; 1996).

Similarly, an analysis of wildlife monitoring in two hunting blocks, one of which was the Munymadzi Corridor of ADMADE indicates that

“measures of hunting effort, hunting success and trophy size for animals hunted by safari clients are also indicators used for assessing population trends and together with trends reflected from respondent interviews, are useful for helping set hunting quotas. The scientific merit of this approach was tested by comparing population sizes, estimated from an aerial counting survey, with relative population sizes as based on their relative quota sizes set by using these indirect indicators. The results will be presented elsewhere in detail but will show a high correspondence between estimated population size from aerial survey and predicted relative size differences as based on indirect measures...other indicators that ADMADE has identified useful for measuring to cross-compare. These between-year changes in 1) Safari client complaints over land use disturbances, poacher encounter rates taken from patrol data, snare encounter rates, and incidence of animal sightings” (ADMADE Foundation, 1999).

Currently, hunting quotas in most of Africa are guesstimates, “thumb sucks”, based on little or no biological data. Very often, they are based on desired economic outcomes for the year and not on good science or business – that is maintenance of the best trophy quality possible as a means of asking top prices for hunting safaris. In this case, good business requires good science to help maintain

trophy quality. The authors wish to make it clear that trophy hunting on its own will not be detrimental to wildlife, as the off-take tends to be between 2 and 5% of the annual population for a particular species. It can be argued that due to the low off-take from trophy hunting, well before there is any danger to a biological population, trophy quality and hunter success will significantly decrease, while hunting effort will increase and trophy hunters will likely go elsewhere and/or the cost of the hunt will have to be significantly reduced. However, cost-effective appropriate monitoring can help identify adverse impacts on a population prior to a crisis as occurred in 1997 when hunting success collapsed with the bongo in Southeastern Cameroon (see Chapter 11, Section 11.11.7.2, Closure of bongo hunting) or a population collapse occurs from factors such as uncontrolled poaching, predator/prey imbalances, drought, diseases, over-grazing from livestock competing for the same pasture and encroachment by farmers. In 2001, the Tshwane University of Technology (TUT), South Africa, and Safari Club International held a series of workshops across Africa, which dealt with the use of trophy quality monitoring and hunting effort as wildlife management tools. As with many short-courses, it is doubtful that these techniques were institutionalized. Newer collaborative programs between the TUT and Sub-Saharan governments (e.g., Mozambique and Zambia) in which government officials, as part of their masters and doctorates must institutionalize such processes, offer more hope! A masters thesis by von Brandis (2004) demonstrated that trophy quality trends could be monitored at a national level. Ultimately, these same techniques need to be applied at the level of a hunting block or blocks that share populations of wildlife – the level at which management must occur in establishing sustainable hunting quotas.

Fairhead and Leach (2003) see this monitoring as a means by which Western science and research, along with the state and NGOs, attempt to move in and control access to community resources by applying bureaucratic requirements and

hurdles through the application of the “precautionary principle” (see Section 9.2.1, Precautionary Principle; Studying Wildlife to Extinction). To some degree, this may be true, especially if sophisticated total counts are required. However, as the ratio of natural resources to human population decreases, increased pressure on the resource base and the modern desire to valorize resources in economic terms will increasingly require the application of Western intensive management systems. For this reason, it will be necessary to train youth from these rural areas in “appropriate and cost-effective monitoring”, planting them back into their communities as resource managers, as a means of minimizing external intrusion into their lives. For instance, in the case study below from southern Burkina Faso, ideally a number of youth from the rural area need to be chosen by the community and sent for tertiary training (see Section 9.8.9.1, Management of the Comé-Leraba Game Reserve, southern Burkina Faso). Shikar Safari Club has just awarded a scholarship beginning in the 2006 academic year to Yaya Ouattara, a youth from this area, to study for a diploma in nature conservation. (Also, see Section 9.7.5, Lack of Technical and Management Skills). This holds true regardless of the resource, be it wildlife, timber, fish, etc.

9.7.7.1 CAMPFIRE, Zimbabwe

The CAMPFIRE program has attempted to bring stakeholders (e.g., safari operators, rural communities, local government, NGOs) together to share data and through consensus establish annual quotas (WWF, 1997; WWF, 2000a; WWF, 2000b). This has occurred through WWF/Zimbabwe acting as a facilitator. Quotas in CAMPFIRE areas are set through a participatory approach, where key stakeholders (e.g., local community, safari operator, WWF, Department of Wildlife and National Parks) bring the above data trends to the table as a basis for decision-making (Figure 9.3). Careful quota setting has maintained the average elephant tusk quality at 40 pounds (Child, 2005 *In: Lyman & Child, 2005*). In 2001, the principal author held a short course in trophy quality and hunting effort

monitoring for the Zimbabwe's Department of National Parks and Wildlife Management (DNPWM) in collaboration with Norman Rigava, then of WWF/Zimbabwe, who has trained stakeholders in wildlife monitoring and quota setting. It is unclear as to whether any of this was institutionalized to deal with hunted game outside of the CAMPFIRE areas.

Quota Sheet 1996: Omay Communal Lands The proposed 1996 hunting and cropping quota for Omay Communal Land

9.7.7.2 ADMADE, Zambia

While Dale Lewis ran his center at Nyamaluma²⁷⁹, on the southern border of the Luangwa South National Park, he attempted to gather information from safari operators based on forms, which they filled out to capture observational data such as trophy quality and hunter success (NPWS, 1990).²⁸⁰ According to Lyons (2000),

“the safari hunting data forms record includes starting and ending dates of a hunt, license numbers, fees paid, species desired by the client before the hunt (used to determine hunting success), species actually killed, wounded animals, locations and dates of animals killed, evidence of snare wounds on animals (added 1999), trophy sizes (following SCI measurement conventions), sex, number of baits (for baited species such as lion), non-hunted trophy animals seen, disturbances to the hunt, poaching activity, client opinions of their hunt and Zambia. The safari hunting dataset is one of the most robust datasets for two reasons. Safari hunting datasets are generally complete, because there are typically only 10-25 hunts per season (per hunting block) and safari hunters are legally required to be accompanied by a scout when hunting”.

Lyons (2000) valued this data as a means of calculating various indices:

- **Trophy quality.** Assuming that animals grow larger with age, and safari hunters are generally selecting trophy animals in the same way from year to year, trophy size is a fairly direct and valid index of the age of the oldest males in the population. This is reason enough to use

²⁷⁹ In 1999, Nyamaluma changed its name to the African College for Community-Based Natural Resource Management (Lyons, 2000).

²⁸⁰ Ian Manning (2006) states that, “other than in the Bangweulu and parts of the Kafue and Barotse wetland system, it is scientifically and economically not feasible to set scientific quotas (total counts with wide confidence limits) in Zambia; rather a ‘good farmer’ harvesting approach is required, based on a set of agreed age and trophy standards, to be monitored at the end of each hunting season, and then adjusted for the next season”.

trophy size as an important indicator, as the success of safari hunting is dependent on trophy specimens. In addition, changes in age structure can reflect changes in abundance in the population as a whole (Lyons, 2000).

- **Hunting success.** Hunting success is the percentage of safari hunters seeking a particular species that successfully found and shot an animal. Before each hunt begins, the village scout accompanying the client is supposed to ask which animals will be sought. At the end of the hunt, the animals actually taken are compared with what was desired to calculate hunting success (Lyons, 2000).
- **Hunting effort.** Hunting effort is defined as the number of days it takes a safari client to find and shoot an animal. When hunting effort increases, it implies that animals are more difficult to find, presumably because there are fewer of them. Hence, hunting effort is therefore also intuitively a good indicator of population change. However like the other indicators, the validity of hunting effort as a proxy for population change requires controlling for or at least averaging out other factors which may affect hunting effort (Lyons, 2000) such as chance encounters.
- **Number of animals hunted.** The total number of animals, which have been legally hunted, is an indication of the off-take from hunting. By itself, the number of animals successfully hunted may not be very meaningful, as it depends on a variety of factors (such as the number of hunters who wanted an animal). However when evaluated with other indicators, the trend is more likely to be valid. The number of animals hunted is also important because it represents the sample size for hunting effort and trophy size, and helps determine the magnitude of any changes in the quota (Lyons, 2000).

Additional data analyzed is poaching/snare records from field patrol surveys, crop damage reports and wildlife population trend surveys. It is also unclear to what degree the GMAs/CRBs have continued with this monitoring process now that Dr. Lewis, as a driving force, is no longer with ADMADE. What is also unclear is to what degree ZAWA used this information to set annual quotas? ZAWA (1999) indicated that this process was beginning but acknowledged that there was a need for greater inclusivity, especially of safari operators, in determining annual hunting quotas. According to Lyons (2000), one-day quota setting meetings of key stakeholders (professional hunter, tracker, community resource board, unit staff, scouts, and NPWS biologist) were held annually in each GMA.

According to Lyons (2000), the relative weight of indicators during group discussions are in descending order of importance:

1. Opinion of the professional hunter – most important (justifiable only if safari operator has long-term and secure lease, otherwise open to abuse for short-term gains);
2. Opinions of the tracker and the scouts;
3. Opinions of others at the meeting (e.g., ex-poachers); and
4. Hunting statistics – least important.

This data appears to never have been institutionalized into the now Zambia Wildlife Authority (ZAWA) headquarters at Chilanga. In 2001, when the principal author offered a basic course in wildlife monitoring in an attempt to institutionalize this process nationally through ZAWA, headquarters had not one piece of Lewis's monitoring data (Kapamba, Simwanza & Zyamboe, *pers. comm.*). If it has not already happened, it is suggested that they recover this information as it could have provided useful trend analyses. According to

Simwanza (2005b), ZAWA has begun developing a Wildlife Monitoring Information System to analyze data collected from a:

- Safari hunting summary form used to verify hunting success;
- Safari hunting daily record form used to determine hunting effort; and
- Trophy measurement form - for monitoring trophy quality.

Quotas are set using this information plus aerial survey data, where available, and poaching levels. A quota setting manual has been developed and one trophy-monitoring workshop has been held, training 35 game scouts from five GMAs. Training workshops for local communities have been undertaken and they are now involved in quota setting, though no numbers were given as to how many communities. In 2007, Edward Phiri, from ZAWA and a master's candidate at the Department of Nature Conservation, Tshwane University of Technology, plans to undertake a thesis that will institutionalize appropriate wildlife monitoring as a basis of quota setting. This is a move in the right direction and it is hoped that the process will evolve. ZAWA is to be congratulated.

Requirement for 75% Quota Utilization

Concern has been raised that Zambia's policy of requiring a 75% (now 56% - see below) use of hunting quotas for each GMA may encourage safari operators to over-harvest game, producing inferior trophies that could harm the reputation of Zambia as a safari destination (ZAWA, 1999) unless:

- Quotas are set correctly;
- Illegal off-take of animals or unusual mortality from natural causes are factored in correctly;
- Quotas once set are not increased by pressures from user groups; and
- Management controls are rigorously enforced.

According to Manning (2006), ZAWA hunting quotas have been set

“...chiefly, by the needs of the lease agreement and the 2003 ZAWA financial budget so...”. Manning (2006) goes on to say “the effect on GMAs when 56% of a quota must be shot by operators must impact negatively on the resource, especially as the illegal offtake is massive and unquantified. Of serious concern is that the 56% minimum offtake would in reality account for 100% of the keystone species on quota: lion, leopard and buffalo”.

9.7.7.3 Botswana Community Trust Program

The Department of Wildlife and National Parks (DWNP) undertakes periodic aerial surveys. It is unclear what kinds of statistical results are obtained since so far the principal author has only seen numbers without standard errors/deviations. Debbie Peake of the Botswana Wildlife Management Association (BWMA), who has a taxidermy dipping and packing company, which ships all trophies coming out of the major hunting areas of the Okavango Delta and Chobe, measures all trophies coming from her operation and in the early 21st century was working on a master’s degree using this information. It is unclear to what degree the DWNP has bought into using this data, since traditionally there has been friction and lack of trust between the DWNP and BWMA. Likewise, BWMA hired a South African researcher, Christian Winterbach, to study lion populations in the Okavango Delta. His findings indicate that the lion population is at saturation within the delta at between 1,189 to 1,668 lions²⁸¹, where until closure 12 trophies/year were harvested, which is 1% or less of the population (Winterbach, 1999 *In: SCI Africa Office, 1999*) – also see Section 9.6.3.4, Botswana Community Trust Program. Due to saturation in the delta, forcing younger males out of the delta into livestock areas, over 100 lion are shot per year as problem animals (SCI Africa Office, 2000a), which places the total harvest/year at about 6-9% as opposed to Funston’s estimate of 5% for the entire country in Section

²⁸¹ Note: Winterbach, *et al.*, 2001 estimate a population of Okavango Delta lion of 1,178 – 1,698 in 1999 compared to from 1,189 – 1,668 in 1998.

9.6.3.4, Botswana Community Trust Program. Ironically, the Okavango Delta is about the only area with a serious lion monitoring program, but as can be seen due to national and international politics, lion hunting was closed, though it used to be a major revenue generator for rural communities (see Section 9.6.3.4, Botswana Community Trust Program). As a result of CITES 2004, where the lion was featured (see Chapter 10, Section 10.8, THERE'S AN AFRICAN LION JUST AROUND THE CORNER), monitoring of trophy hunted lion and lion populations will significantly improve in Botswana and elsewhere as the outcome of a series of workshops on the subcontinent in 2005/6.

9.7.7.4 Tanzania

The Wildlife Division, through their research branch, undertakes aerial surveys, employing antiquated techniques with large standard errors. This makes the use of this information of questionable value for key management decisions such as quota setting. In the mid-1990s, a grant from the U.S. Fish and Wildlife Service was implemented by safari operator/wildlife biologist Rolf Rohwer in the Selous Game Reserve (SGR) (Rohwer, 1995; 1996). The goal was to institutionalize the collection of baseline wildlife monitoring data by safari operators at a more cost-effective and appropriate level. This concept was rejected by the operators, fearing among others that geographically referenced data might show them hunting in areas outside of their licensed concession or at the wrong time of the day or otherwise in violation of game laws (Rohwer, *pers. comm.*). Since it was not a legal requirement by the Wildlife Division, it failed. With regards to wildlife monitoring, sustainable utilization of Tanzania's wildlife populations faces the following challenges in the future (SCI African Chapter, 1996):

1. Unrealistic subdivisions of hunting blocks and multiplication of quotas by the Wildlife Department for short-term economic gains, without appropriate biological and ecological data to substantiate these gains; and
2. Guesstimate hunting quotas with no scientific validity that could lead to unsustainable utilization, both economically and ecologically. Often hunting blocks have quotas for game not in their area, while in other instances quotas are believed to be too low, decreasing the economic sustainability of the hunting blocks.

The backbone of the safari industry in Tanzania is the lion, leopard and buffalo, responsible for 42% of the trophy fees on which the Wildlife Division makes the majority of its income from hunting. Buffalo are the most important species, contributing 22.1% of the trophy fees, which represents 13.3% of the total Wildlife Division income (Baldus & Cauldwell, 2004).

Aerial surveys, currently the primary means of monitoring wildlife, are not able to cover all hunting areas due to cost and are unable to provide data on these three key species (Baldus & Cauldwell, 2004), lion and leopard because of their cryptic nature and buffalo due to non-random clumped distribution of herds that often require total counts even from the air. Deriving scientific estimates of lion and leopard populations requires detailed studies over several years and is not feasible to accurately measure populations in the vast extensive hunting blocks of Tanzania and most of Africa. Trophy quality over time has been measured in the Selous Game Reserve (SGR) since 1999 and is recommended countrywide along with trends over time in animal abundance and hunting success (Baldus & Cauldwell, 2004). In Tanzania, an average of 20,500 hunting days sold to 1,370 clients results in the harvest of 7,500 animals/year, representing 60 species, which makes the monitoring of off-take an enormous task. Both the Planning and

Assessment for Wildlife Management (PAWM) project funded by USAID from 1990 to 1995 and GTZ (Broomhead, 1997 *In: Baldus & Cauldwell, 2004*) recommended computerization and collection of wildlife management data that was rejected by the Wildlife Division.

“The WD (Wildlife Division) has twice resisted attempts to computerize the system. It is doubtful that in the absence of proper records management an adaptive management approach can be practiced (d)...There is a tendency for outfitters to be allocated their required hunting quotas, and that quotas are increasingly raised regardless of the population status. Hence, quotas are not based on ecological indicators but rather economic interests of a few powerful players” (World Bank, 2005).

Currently, the Wildlife Division relies on qualitative recommendations from project managers and district game officers as well as safari operators/professional hunters, opening the system up to unjustifiable quotas for short-term economic gains. “Some people allege that the Wildlife Division is purely a financially driven organization...” (Baldus & Cauldwell, 2004). The net result is the unsustainable hunting of key species where age and quality has declined (e.g., lion, buffalo) (World Bank, 2005)

“in part due to the lack of an objective system for quota setting for hunting, and many hunting quotas are issued that allow unsustainable levels of hunting. Hunting also takes place ‘above’ quotas” (DPG, 2005).

Data also suggests a decline in numbers of lion and leopard being hunted/year and/or quotas that are too high based on hunting success (only one in five clients takes a lion trophy) and the fact that only about 40% and 60% respectively of the lion and leopard quota are utilized each year (Baldus & Cauldwell, 2004).

Combined with computerization of the system, Baldus & Cauldwell (2004) recommend the following:

- Available data from aerial and ground census;
- Standard questionnaires completed by wildlife scouts accompanying clients on hunts on animal abundance, sightings, hunter success, etc.;
- Trophy quality, possibly age for lion and leopards; and
- Village scout data in Wildlife Management Areas (WMAs).

The “*Revised Draft Policy and Management Plan for Tourist Hunting*” (Department of Wildlife 1995 *In: Baldus & Cauldwell, 2004*) laid out the foundation for monitoring that has never been implemented.

Also according to Kibonde (*pers. comm.*), the Selous Game Reserve (SGR) is initiating a wildlife monitoring program of its off-take. According to DPG (2005), a tourist hunting (sport hunting) database for the Selous began in 1988 with the addition of hunting trophy quality monitoring in 1998. “The database (without trophy monitoring) has been expanded for game reserves in northwestern Tanzania” (DPG, 2005). In the Selous, game guards with each vehicle record harvest information such as trophy quality along with a GPS location of the harvest. The Selous is divided into eight sectors with three to five personnel/sector with diplomas in wildlife management plus a warden in charge/sector. The staff makes a 100% quality control check on all trophies to verify the game scout’s data. Currently, a person is being trained in statistical analysis and a university professor from Tanzania has been contracted to train the wardens in data collection and analysis (Kibonde, *pers. comm.*). What is not clear, is to what degree such information is being used to establish quotas.

Tanzania Game Trackers/Wengert Windrose Safaris, a hunting company in Tanzania, and Dallas Safari Club, an American sport hunting club, are funding two masters students from the Wildlife Division's technical branch, Tanzania Wildlife Research Institute (TAWIRI), in collaboration with the Department of Nature Conservation, the Tshwane University of Technology (TUT), South Africa. The goal is to develop and institutionalize an integrated program involving both aerial and on-the-ground data collection on wildlife utilizations and populations in hunting blocks. Modern distance sampling techniques will be employed to increase the reliability of the data. So far, only the aerial survey portion of this agenda is being met, with a reluctance to be involved in a systematic collection of ground data (e.g., trophy quality, hunter success/effort, herd structure and size, recruitment, poaching, etc.). Once again, the analysis of such data may not be in the government's interest as it goes for short-term and short-sighted economic benefits.

In mid-2004, Tanzania passed a law making it illegal to shoot any lion under six years of age, an age limit based on work undertaken by researchers such as Craig Packer, that if followed should help maintain healthy lion populations, assuming that other off-takes [e.g., Problem Animal Control (PAC)] are insignificant in and around the hunting blocks. The next step is to hold a workshop to identify key field indices that professional hunters can use to identify mature lions. The Wildlife Division will require various information such as photos and will personally measure skulls and look at skins in determining if they are legal to export (Oelofse, *pers. comm.*). In 2006, a guide for professional and sport hunters was published as an aid in judging a lion's age (Whitman & Packer, 2006). This should set a precedent for other Sub-Saharan African countries where lion is one of the most valuable species for the safari industry.

Demonstrating the importance of monitoring, a November 6-21, 2004 lion survey of Moyowosi's Njingwe South hunting block may justify the above concerns. The area surveyed included Moyowosi Game Reserve's Njingwe South area ($2,870 \text{ km}^2$) in the southern part of the game reserve. Using the calling a station technique, based on the area sampled with lion calling stations (614 km^2) the Njingwe South lion population is estimated at 91 lion or about 3.3 lion/ 100 km^2

"significantly higher than the general lion density given for the Moyowosi/Kigosi Game Reserves and surrounding areas. Elsewhere in Tanzania an average lion density of 15 lion/ 100 km^2 has been suggested for the Serengeti-Ngorongoro-Tarangire region and 8.0 lion/ 100 km^2 in areas such as Mikumi National Park and Selous Game Reserve (SGR)...No adult male lion were recorded although seven female lion were at the calling stations. Most of the lion (70.0%) were younger than 4 years, and only 3 (15.0%) were younger than 12 years. The oldest males were estimated to be about 3.5-4 years old. Lion considered being adults comprised 35.0% of lion recorded" (Viljoen, 2004).

Since 2002, the quota has been three lion/hunting season (Viljoen, 2004). The annual hunting quota of three lion amounts to 3 % of the population and is likely sustainable.

Subdivision of Hunting and Quota Multiplication without Scientific Basis

In 1965, when Tanzania's wildlife population was higher than today, there were 47 hunting blocks. By 1997, the number increased to over 140 hunting blocks. Baldus and Cauldwell (2004) use the figure of 141 hunting blocks. At the same time, the number of hunting companies increased from nine in 1984 (Nshala, 1999) to 42 by 2004 (Table 9.16):

Table 9.16: Growth in hunting companies, Tanzania

YEAR	NUMBER	SOURCE
1984	9	Nshala (1999)
1988	21	Nshala (1999)
1995/96	42	TAHOA (2001)
1996/97	35 [33]	TAHOA (2001); Nshala (1999)
1998	35	TAHOA (2001)
1999	35	TAHOA (2001)
2000	39	TAHOA (2001)
2004	42	Baldus & Cauldwell (2004)

Prepared by principal author

“The first time this idea (sub-dividing hunting blocks) was raised was in a PAWM²⁸² (Planning and Assessment For Wildlife Management) Workshop in 1993. Expatriate Experts, participating in this workshop, believed that there were many hunting concessions that were under-utilized and that sub-dividing them would allow greater use of the resources and allow more hunting operators to enter into the business. It was also believed that this would break the monopoly of the large operators (about 6 large at the time), and drop the price of hunting (at the time the highest in Africa and still the case) helping Tanzania to be competitive in the market place.

The safari industry immediately called a meeting with the Department of Wildlife and explained that all of this was theoretical, and that Tanzania could not sustainably support such utilization pressures on its game.

Ultimately, many of the PHs and safari operators interviewed believe that one or two big operators pushed for the break-up of hunting blocks in order to get hold of prime areas, especially access to the unique Maasailand species (e.g., access unique species such as the Lake Natron area famous for its lesser kudu and gerenuk). .

This was also exasperated by the fact that the Department of Wildlife must be self-financing, behaving like a parastatal. The government’s viewpoint was that by breaking up the hunting blocks and increasing overall quotas for a given geographical area, more money would come into the government” (SCI African Chapter, 1996).

²⁸² PAWM was funded by USAID (Barrow, *et al.*, 2000)

It is also believed that the breaking of this monopoly by a few big safari operators through the subdivision of hunting blocks was undertaken as part of the indigenization process, to get more black Tanzanians involved in the safari industry (SCI Africa Office, 2001a). Still, after all of this, about 90% of the safari hunting revenue in the mid-1990s was still being generated by five to seven foreign owned companies (SCI African Chapter, 1996). Baldus and Cauldwell (2004) recognize three major consortiums of hunting companies under common ownership holding 36% of all hunting concessions:

- Gerard Pasanisi, Barlette Safaris and Tanganyika Wildlife Safaris owned by Gerard Pasanisi, a French Corsican and family with a total of 20 concessions controlling 35% of the concessions in the Selous plus concessions in Open Areas adjacent to the Selous Game Reserve (SGR). In addition said to have one of the largest eco-tourism companies in Africa if not the World;
- Tanzania Game Trackers (TGT) – Wengert Windrose Safaris (WWS) Group owned by Tommy Friedkin of Texas with 15 concessions; and
- Tanzania Big Game Safaris, Tandala Safaris and Tanzania Safaris and Hunting Group owned by Raul Ramoni with 16 concessions.

Subleasing

A major problem is that many of the indigenous companies do not have the marketing skills and as a result sublease to foreigners, often South Africans. Up to 70% of the safari companies leasing hunting concessions sublease in various ways, accounting for up to 40% of the industry's income. It is estimated that 30% of the gross turnover from hunting never enters the country, fees being collected offshore by the foreign professional hunters subleasing. This would amount to an annual loss of from US\$ 8-11 million/year of the US\$ 27-39 million/year gross turnover of Tanzania's safari hunting industry from subleasing (Baldus & Cauldwell, 2004). As discussed, most of the indigenous safari operators were/are a political/bureaucratic elite who extract the wealth out of their area with little or

nothing going to rural communities and in some cases, worse, through subleasing allow over-shooting of their areas by unscrupulous foreigners for short-term gain.

Larger companies that tend to charge high daily rates and offer exclusive high product experiences also tend to deliberately under-utilize their quotas, while smaller companies with a poor client base tend to sublease, thus losing direct income. These marginal operations will tend towards over-utilization of wildlife by pushing for higher quotas, with little or no biological data to justify increases, increased turnover being their only way of generating adequate returns on their investment. The small companies sublease at US\$ 600-700/day to wandering professional hunters, while the wandering professional hunter charges the client US\$ 1,500-1,800/day resulting in a loss of US\$ 800-1,200/day that must be made up, helping explain the loss of FOREX to Tanzania. Increasing quotas for short-term gain is the obvious remedy. It is also estimated that in some instances, entire concessions are subleased at values of up to 20x the rate (in excess of US\$ 130,000/year) leased from the Wildlife Division that is currently fixed at US\$ 7,500/block/year (Baldus & Cauldwell, 2004). Block and concession fees increased significantly in 2007, likely decreasing private sector profits and increasing government profits (see, Section 9.6.3.6, SCP, Tanzania). There is much to be made of being an absentee landlord in Tanzania's hunting industry, but is it sustainable?

Subdivision of Northern Maasailand Hunting Blocks

For instance, the Northern Maasailand hunting concessions were first subdivided from two to six hunting blocks (SCI African Chapter, 1996; Wengert, *pers comm.*). Wengert Windrose Safaris had its two hunting blocks in northern Maasailand, Lake Natron and Mto-Wa-Mbu subdivided between five companies, TGT (Tanzania Game Trackers), Robin Hurt, Wengert-Windrose, Intercon and TAWICO (Tanzania Wildlife Corporation – hunting company) (SCI African

Advisory Board, 1997). Quotas in Maasailand went from (Wengert, *pers. comm.* In: SCI African Chapter, 1996) (Table 9.17):

Table 9.17: Subdivision of Wengert-Windrose Northern Maasailand hunting blocks, from 2 to 5 early 1990s and multiplication of safari hunting quotas without biological data

	<u>Prior to Subdividing</u>	<u>After Subdividing</u>	<u>Increase</u>
Lesser Kudu	9	56	6.2 x
Gerenuk	9	60	6.7 x
Grants Gazelle	15	200	13.3 x

Source: DeGeorges In: SCI African Chapter (1996)

In addition to safari hunting quotas, quotas were given for game capture and game cropping. Resident hunters were also given quotas. This is resulting in a major drop in trophy quality because of too high a harvest rate (SCI African Advisory Board, 1997). There was no scientific basis for this level of increase in quotas. It appears to have been an economically based decision and while some increase may have been acceptable, certainly not to the extremes as noted above (Wengert, *pers. comm.* In: SCI African Chapter, 1996). Franz Wengert (*pers. comm.*) believes that some companies overshot their quotas and then arranged to have their quotas officially adjusted upwards after the season was over.

Subdivision of Southern Maasailand Hunting Blocks

Beginning in the 1950s, there were only two hunting blocks around the Tarangire National Park (TNP), Southern Maasailand (DeGeorges, 1999b):²⁸³

²⁸³ Interviews were held with contacts at the outpost, Arusha, with former and active professional hunters who have a thorough understanding of issues from having actively hunted the blocks around Tarangire; as far back as 20 years ago. These include: 1) safari operator George Angelides, 2) former PH and commercial farmer - Michael Smalling (brother Marshall), 3) former PH and well-known sculptor - Dave Schaefer and well-known PHs: Steve Attwell, Andre Roux, Andy Wilkinson and Nigel Thiesen.

- Maasai Open Area
- Maasai Game Control Area (GCA) – no resident hunters allowed

These areas had no permanent hunting camps. Mobile tented camps would obtain a quota and take up temporary residence while hunting with a client and then move on.

Beginning around 1988, the Wildlife Division started sub-dividing the hunting blocks with these two blocks being turned into eight hunting blocks. The Maasai control area was subdivided into Lolkisale, Loibor Siret, Simanjiro West and Simanjiro/Kitiengare. The Maasai Open Area was divided into the Naberera, Mkungrunero, Makuyuni and Kondoa. As in the Lake Natron area, when subdivided, the old quotas were given to each of the new blocks, resulting in quotas being multiplied by as many as four times or more for short-term economic gain with little or no biological data to justify these subdivisions or to determine if they were sustainable. Such subdivisions of hunting blocks are not unique to Tanzania, but are believed to have happened in a number of countries for similar short-term economic gains with little or no biological data to justify these actions. According to Ruchaud (*pers. comm.*),²⁸⁴ this happened to hunting blocks in the Northern Province of Cameroon (see Chapter 5, Section 5.9.3.4, Over-population and livestock, a threat to wildlife in northern Cameroon). In 2005, Zambia also subdivided a number of hunting blocks, it is hoped for the right reasons and with appropriate data. However, high level donor contacts within Zambia, indicate the subdivisions were not based on adequate scientific data, being primarily for short-term economic gains (Anon 2006, *pers. comm.*).²⁸⁵

²⁸⁴ Rene Ruchaud, 10 Rue du General, DeGaulle, 85150 Vaire, France, Tel: 33-51-33-7127

²⁸⁵ According to Ian Manning (2006), “The 2004 ZAWA quota report stated that some hunting blocks had been subdivided and the quotas increased as ‘each hunting block must meet the requirements in terms of the minimum number of classical and mini safaris depending on its status.’ It further states that because all classical and mini safaris require a buffalo, ‘This in

Subdivision of Moyowosi “Njingwe” South Hunting Block

The Moyowosi, Tanzania, is a Ramsar (International Convention on Wetlands or “The Ramsar Convention” signed in Ramsar, Iran) wetlands site created among other reasons to protect the endangered shoebill (whale-headed) stork (*Balaeniceps rex*). Aerial surveys by the Tanzania Wildlife Conservation Monitoring Unit/TWCM, renamed Tanzania Wildlife Research Institute (TAWIRI), were used at the political level to split the Moyowosi South hunting block in two in 2001.

“Species such as sable, roan and buffalo are not evenly distributed and in cutting the block one of the blocks would contain sable and roan, while the other would contain much of the buffalo. Lion are already pressured and plans existed by safari operators to reduce the quota. Now the quota will be doubled. Aerial surveys conducted in 1990/1994/1998/2000 show a stable or decreasing trend in most game and an increase in human encroachment. There was a misjudgment on the size of the hunting area, plus the actual accessible area is quite limited, as much of the block is swamp. Aerial censuses of wildlife have large confidence limits. There were an estimated 350,000 Tutsi Refugees heavily impacting the southern section of the block. Cattle in the hunting area were estimated at 29,771, lower limit 7,999 and upper limit 51,543 in the 2000 survey. During the same survey, the buffalo estimate was 8,132 with a lower limit of 187 and an upper limit of 16,077 making this data...useless for setting quotas. The aerial census reports put out by the Tanzania Wildlife Conservation Monitoring Unit state that buffalo in the 1970s were estimated to be about 20,000 (TAWIRI, 2001 *In:* DeGeorges, 2001a *In:* SCI Africa Office, 2001a). Safari operators noted that 20 years ago there were

practice entails that the minimum number of buffaloes for a prime hunting block should be 12 and a secondary block, 8. Thus quotas have been prepared and adjusted with this situation in mind.’ Clearly, quotas are therefore massaged to meet the safari package requirements of Prime or Secondary areas in order for ZAWA to exact the maximum income”. This occurred again in 2005 and 2006 with further subdivisions to meet ZAWA’s short-term economic goals (Manning, 2006). ZAWA lacks “...the necessary scientific, managerial and operational capacity, and (is) guided more by the necessities of income generation over biodiversity conservation...” (Manning, 2006).

buffalo herds of 6,000 animals. Today, if one sees herds of 600 you are lucky" (Oelofse, *pers. comm.* In: DeGeorges, 2001a In: SCI Africa Office, 2001a).

Since then the block has been reconstituted into one. This subdivision of hunting blocks is believed to be having a major negative impact on trophy quality and in combination with other factors (e.g., human encroachment, poaching) potentially on the economic and ecological viability of game populations over much of Tanzania's hunting areas.

As a sequel, in September 2004, TUT graduate student Harley (*pers. comm.*) flew with TAWIRI personnel to undertake aerial surveys using more precise distance sampling. The safari operator (Oelofse, *pers. comm.*) thought the cattle had been removed. Harley (*pers. comm.*) estimates that there are only 1,000 +/- 300 buffalo and 22,500 +/- 2,500 cattle in the Moyowosi South hunting block. The biggest herd of buffalo observed was about 400. Once again, communities see little or nothing economically from wildlife, but place great value in the livestock, which has both economic and cultural value to them. Unless things change, one must expect that in the long run buffalo numbers will continue to decline in the Moyowosi and cattle numbers will continue to increase. Repression by safari operators and/or government will only slow the change. Until local people have a vested economic and psychological stake in this and many other natural areas across the subcontinent, wildlife and these natural systems face a bleak future. Conservation as currently practiced is failing Africa and Africans.

40% Quota Utilization Requirement, Tanzania

Similar to Zambia, with no appropriate scientific data, another policy which is believed to be very dangerous to the sustainability of safari hunting is the requirement for 40% financial utilization of the quota, rather than a 40%

utilization of the trophy quota. This is the minimum required in order to retain hunting blocks by a safari operator. In theory, this gives the safari operator the ability to rest game whose trophy quality may be deteriorating, as long the government receives minimum guaranteed revenue. This is fine except that most quotas are not based on scientific data and are believed to often be too high. Many feel that this results in over-shooting hunting blocks as opposed to shelling hard-earned money out of one's pockets for quotas that are abnormally high and thus putting undue financial burdens on the private sector (SCI African Advisory Board, 1997). The increasing number of buffalo, wildebeest and zebra hunted each year could be a reflection of pressure put on safari operators to meet the 40% rule while faced with declining lion and leopard hunts (Baldus & Cauldwell, 2004).

9.7.7.5 Attempts at institutionalizing appropriate wildlife monitoring in other Sub-Saharan African countries

With little success, the Tshwane University of Technology, South Africa, has also been trying to initiate a wildlife-monitoring program with Cameroon to institutionalize this process in both the forest and savanna hunting areas.²⁸⁶ Emphasis will be placed on using professional hunters, game guards and eventually rural communities who are on the ground to record field observations such as trophy quality, hunter success/effort, herd size and structure, recruitment and disturbances/encroachment such as poaching, itinerant agriculture, etc. This cost-effective information will be used to establish hunting quotas and to take

²⁸⁶ TUT, at its own expense flew down masters candidate Georges Mouncharou, head of Cameroon's elephant program and conservator of the new head of the elephant program for the country and the new head of the Mbam and Djerem National Park and doctoral candidate Assan Gomse, head of the Benoué National Park. Draft thesis proposals were prepared but never followed up by the two candidates. For the moment, the Cameroon program is moribund. A November 2005 visit to Cameroon by a TUT staff member tried to push this initiative forward with little success.

other interventions in assuring the economic and biological viability of wildlife populations. To date little is happening.

TUT is also working with Mozambique with goals of this program taking off in 2005. WWF held a trophy quality-setting workshop for the government and hunting industry in 2005. To date (early 2008). In this case, it is difficult to determine whether the problem lies with the individual and/or complacency by the key stakeholders (e.g., government and the private sector). An M-Tech student from Zambia's ZAWA plans a pilot trophy quality/hunting effort and success monitoring program (Phiri, 2006).

What has been described above regarding Tanzania's wildlife monitoring can be alleged for most of the government hunting bodies on the subcontinent. Cameroon, Mozambique and Zambia to date have failed to initiate countrywide programs. There is still concern across the subcontinent about how committed governments and safari operators are to basing trophy hunting quotas on biological data to assure both long-term economic and ecological sustainability as opposed to meeting purely short-term economic goals. Assuring long-term tenure and security over hunting leases to the private sector could go a long way in helping to get a buy-in from them. With more and more wildlife departments becoming parastatals and having to be economically independent, there is a strong risk that short-term economic goals will prevail even within governments, resulting in a potential abuse of wildlife resources. As discussed, structural adjustment policies (SAPs) that result in a countrywide economic decline also tend to encourage unsustainable harvesting of resources by all stakeholders. The next few years will be telling.

Concern is raised that the shortage of data by the hunting industry will in the future lead to mistrust from the international community at forums such as

Convention on International Trade in Endangered Species (CITES), Convention on Biological Diversity (CBD), and among national bodies such as the U.S. Fish and Wildlife Service or the EU (Baldus & Cauldwell, 2004).

9.7.8 Lack of Adequate Alternative Livelihoods

Where the natural resource supply is high and human demand is low, the need for control is low. When the natural resources supply is low and the human demand is high, the need for control is high. Factors such as 1) natural human population increases, 2) uncontrolled immigration, sometimes by outsiders moving into the area to obtain benefits from the natural resources and from areas in internal and regional civil strife, or 3) an absence of non-rural livelihood alternatives all pose a serious threat to CBNRM.

Sub-Saharan Africa is the only region of the world where the annual growth of gross domestic product (GDP) per capita has been negative, at -1.0% between 1975 – 1999, compared to 6.0% for East Asia and the Pacific and 2.3% for South Asia (Roman, 2003). Failing national economies and the lack of opportunity in the cities is resulting in the “politics of despair” in which rural dwellers who emigrated to the city “paved with gold” find no opportunity and are thus forced to return to the rural areas, often “mining” the natural resources in trying to survive (e.g., itinerant agriculture, extensive pastoralism, charcoal making, illegal hardwood cutting, artisanal mining, honey collecting, poisoning waterholes for fish and poaching). Thus, national macro-economic health and CBNRM are integrally linked.

The *Tchuma Tchato* Project in Mozambique has had major problems with uncontrolled migration of people from neighbouring areas looking for new opportunities and benefits. This immigration is the result of deteriorating

conditions in their areas of origin and also of the project, as it offers some jobs and minimal benefits. Moreover, floods in 2001 as well as changed hydrological management practices at the Kariba and Cahora Bassa Dams provoked the inundation of fertile lands along the lake, forcing people to move to safer areas close to or on animal routes. In the district of Zumbo, nine cases were reported of people killed by animals, mainly by elephants and hippopotamuses. The real number is probably higher since most cases are not reported (Nimpuno, 2003). The safari operator has complained that this in-migration and settlement of people is interfering with buffalo migratory routes (Hougaard & Rouget, *pers. comm.*).

As an example, the 1994 Rwanda genocide, forced thousands of Tutsi across the border into northwestern Tanzania into refugee camps that placed tremendous pressure on forests for fuelwood and wildlife for food. The civil war in the DRC forced hundreds of thousands of internally displaced people (IDPs) into national parks cutting firewood and poaching to survive (see Chapter 13, Section 13.10.3.7, Impacts on biodiversity).

9.7.8.1 Politics of despair, Zambia

The following mini-case study demonstrates how a combination of 1) traditional beliefs of hunters and 2) a lack of opportunities in urban centers can push people back into rural areas, doing whatever it takes to survive, even if this means mining wildlife and other resources for short-term survival needs (DeGeorges, 1992a).

While the principal author was visiting the Munyamadzi GMA during an evaluation of ADMADE for the Zambian government and USAID in 1992, four poachers were brought into the camp by the village scouts. The ringleader was an old man in his 60s. His history might be considered as typical of many “poachers” who today transition back and forth between urban and rural areas. He started his life as a miner in the Copper Belt of Zambia. He claimed that as a miner he often “dreamed” of hunting, which might be interpreted as a dream summons from his ancestors. He

was involved in a mining accident and returned to his home in the vicinity of Mpika in order to rehabilitate. While there, an elephant got into a field and his uncle gave him a muzzleloader with which he killed the elephant. He reported this incident to the chief and was given the meat. After a month of recuperation, he returned to the mines. This was 1965.

In 1972, he stopped working in the mines after a number of near fatal accidents that caused him to fear for his life. He began hunting for the pot after that. He met a businessman near Ndola who had an elephant license and who hired him to go into the Machiya Fungulwe GMA to shoot his elephant. He did this twice, finding out how lucrative elephant hunting can be. He began purchasing his own elephant licenses from Lusaka and shooting elephant in order to sell the meat in Lusaka. He did this three times.

Then in, 1974, he joined a "Senegalese poaching ring" that smuggled ivory. He worked with them through 1986 when the Senegalese were thrown out of the country. He had been caught several times in the Munyamadzi GMA, as recently as January 1992. He claimed that if he was not in the bush for two to three months, his body stiffened and that he got the urge to hunt. If he could get a job like going with the scouts, it would make him happy and keep him busy. He explained that if put in jail for two years, he would likely return to poaching on his release. Three young boys apprenticing under him were urban poor:

- The 17 year-old said he didn't know what he was getting into and that he only went along because he had been told to do so;
- The 19 year-old had been poaching with the old man since 1987; and
- The 23 year-old had been poaching with the old man since 1991.

This is the first time any of these young men had been caught for poaching. The game scouts, who were interviewed throughout the evaluation, agreed that prison was not the solution. As a number of them said, "We have one of two choices, either shoot them or help them find viable long-term employment". This same

statement was echoed to the principal author while in the Fouta Djallon Mountains of Guinea-Conakry, with traditional Fulani *marabou* lion and leopard hunters.

9.7.8.2 “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”

“The alienation of indigenous peoples by conservation authorities has been reinforced by the sharp discontinuity that has developed between the social and economic situations inside and outside African nature reserves. Nature reserves (today 21st century) generally represent active economic centers with high income-generating potential based on sustainable land-use practices. In contrast indigenous people surrounding nature reserves generally have low income-generating potential, and are poorly educated...As population numbers increase and the demand for resources grows, the frequency and intensity of conflict between protected areas and local indigenous people will increase ”(Venter, Breen & Marais, 1994 *In: Fabricius, et al.*, 2001).

Southern Maasailand is another fine example where people, flocking back out of the urban centers, who undertake charcoal making, commercial bushmeat hunting and farming among others, are risking the future of wildlife in this area. This immigration, along with changing land use practices is threatening the entire Simanjiro/Tarangire Ecosystem of Southern Maasailand, Tanzania.

The following is extracted from DeGeorges (1999b). Interviews were held with former and active professional hunters who have a thorough understanding of issues from having actively hunted the blocks around Tarangire as far back as 20 years ago. These hunters include: 1) safari operator George Angelides (company sold in 2003), 2) former PH and commercial farmer - Michael Smalling (brother Marshall), 3) former PH and well-known sculptor - Dave Schaefer and 4) well-known PHs: Steve Attwell, Andre Roux, Andy Wilkinson and Nigel Thiesen. For many reasons, game populations are estimated by most people to be 10% of what they were ten to 15 years ago in this Southern Maasailand area. The decline

in game numbers and trophy quality includes: buffalo (*Syncerus caffer caffer*), lion (*Panthera leo leo*), leopard (*Panthera pardus pardus*), gerenuk (*Litocranius walleri*), lesser kudu (*Tragelaphus imberbis*), Cokes hartebeest (*Alcelaphus buselaphus cokei*), fringe-eared oryx (*Oryx gazelle callotis*), southern Grant's (*Gazella granti granti*) and Thomson's (*Gazella thomsoni thomsoni*) gazelles.

In the simplest terms, the 2,642 km² Tarangire National Park (TNP), gazetted in 1957, is a dry season grazing area for wildlife. In the past, it was also a dry season grazing area for the Maasai cattle, one reason why many Maasai are alienated from this park (see Chapter 3, Section 3.8.4, Land Compression and the Maasai of Kenya and Tanzania). It can be said to be an incomplete ecosystem. The rainy season dispersal area on the Maasailand outside of the Tarangire National Park (TNP) is critical to the wildlife populations in the park, similar to the Serengeti, Maasai Mara and Amboseli. Wildlife spends up to six months of the year in these dispersal areas (Kangwana & Ole Mako, 1998), drops and raises its young. Without these rainy season areas, the numbers and diversity of wildlife would be greatly diminished and dry season habitat would be degraded by game remaining year-round in the park (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya). It is estimated that 90% of the Tarangire Ecosystem grazing area is outside of the park. "Corridors" or migratory routes east of the park, going into game control and Open Areas, are being lost from human encroachment. Similarly, though believed to be less affected, human encroachment is also impacting the western migratory route. The net result is that game populations, both within the park and in the hunting areas to the east, have been greatly reduced.

Beginning in 1988, the two hunting blocks around the TNP, the Maasai Open Area and Maasai Game Control Area (GCA), were subdivided into eight hunting blocks, the quota increasing about four times (DeGeorges, 1999b) (see Section

9.7.7.4, Tanzania). Major reasons for game population declines and/or conflicts between humans and wildlife include the following, not necessarily in order of priority:

Agricultural/Pastoral Related

- Agriculture - Maasai selling off land within hunting blocks to commercial farmers
- Squatting by subsistence farmers;
- Over-grazing by Maasai cattle, goats and sheep – exceeding carrying capacity and competing with wildlife for food, water and space;
- Uncontrolled and unplanned placement of boreholes for livestock by religious groups, which are mismanaged and are resulting in desertification;
- Migratory routes northwest to Lake Manyara and east to Lolkisale/Simanjiro affected by human habitation/encroachment;
- Disease such as rinderpest has affected buffalo and greater kudu, while malignant catarrhal fever (MCF) has impacted cattle when they come in contact with wildebeest and wildlife carried tick-borne diseases; and
- Predation of livestock by lion and human attacks by buffalo (Kangwana & Ole Mako, 1998).

An increase in competition for land and resources in Tanzania has grave implications for both wildlife and people. In fact between 1967 and 1988, the human population of the Tarangire-Manyara ecosystem experienced a growth rate of 8.2%/year (Maliti, 2007) versus a national rate of 2.9% (see Section 9.6.1.2, Kifluku Farm, Laikipia, Kenya). Wildlife populations have experienced drastic declines while livestock populations have increased. Based upon aerial surveys by TAWIRI, wet season populations of the most numerous wildlife in the

Tarangire-Manyara ecosystem, wildebeest (*Connochaetes taurinus*) concentrated largely in the Simanjiro plains east of the park during this period, have declined from a high of 43,539 in 1988 to 5,257 in 2001, while cattle have increased during the same time frame from 53,828 to 240,842. This latter figure is ten times higher than the most abundant wildlife species in 2001, the zebra at a wet season population of 25,280 (41,073 in 1988) (Maliti, 2007). In addition,

“important corridor and dispersal areas east of Tarangire National Park, experienced almost complete clearance of woodland from 1995 as consequence of the expansion of smallholder cultivation, an expansion that has continued to the present day” (Maliti, 2007).

Farm plots increased from 1,051 in the wet season of 1988 to 49,114 during the wet season of 2001 in the Tarangire-Manyara ecosystem, largely in the Simanjiro plains (east of Tarangire National Park (TNP), impacting the migratory routes of wildlife, especially wildebeest (Maliti, 2007). Kwangwana and Ole Mako (1998) state that in the Loibor Serit area, 90% of the people interviewed in 1997 wanted the size of Tarangire National Park (TNP) reduced due to land hunger as described above. They argue, as this case study, demonstrates that

“efforts at benefit sharing cannot be seen as a replacement for initiatives to minimize the problems people incur in living with wildlife. People reported the same problems of living with wildlife in 1997 that they reported in 1992, and there was little evidence of a concerted effort to address these...Contrary to much current CC (community conservation) theory which posits that wildlife will be conserved to the extent that it provides ‘economic’ benefits, conservation in TNP appears to be dependent on a complex and dynamic interaction between cultural values, livelihood issues, human relationships and economic benefits...An increasing amount of land is being cultivated to the east of the Park, expanding the range of conflict between agriculture and wildlife. The single most important issue determining conservation possibilities in and around TNP is landuse”.

Even to the West of the park in 1999 the principal author observed village huts right up to the park entrance, something that did not exist in 1992 when he had last visited the area. With similar adverse impacts on wildlife populations, human encroachment has nearly eliminated wildlife corridors in the Ngorongoro Conservation Area (NCA) (Estes, Atwood & Estes, 2006).

Hunting Related

- Uncontrolled resident²⁸⁷ hunting, often commercial poaching for the bushmeat trade;
- Farm abuse: game cropping in the name of PAC animals for the bushmeat trade;
- Grass roots commercial poaching for bushmeat trade, even by Maasai, both in and outside the park;
- Revenge killing by Maasai out of anger from little or no benefit from wildlife that competes with their livestock for pasture and space;
- Unrealistic hunting quotas;
- Abuse of quotas by PHs;
- PHs hunting in someone else's block; and
- Unrealistic game cropping quotas by the Tanzania Wildlife Company (TAWICO).

Western (2005 *In:* Lyman & Child, 2005) sums up the feelings of the Maasai best.

“Maasai exclusion from any share in tourism, and the huge losses they suffered from wildlife, was fast eroding their traditional tolerance and making enemies where wildlife could least afford it.

²⁸⁷ In Tanzania, resident implies citizen hunters, usually from the cities, where in Zambia a resident hunter is a local from within a game management area, and a non-resident is a citizen usually from the city.

Wildlife had, in the words of the Maasai, become government cattle rather than their fallback reserve in droughts”.

Although based on his experiences around Amboseli, Kenya, it equally applies in Tanzania and much of the rural communities of Sub-Saharan Africa.

Other Human Activities

- Gemstone (tanzanite) mining and associated poaching; and
- Charcoal making resulting in habitat loss

In addition, a problem is presented by the drought affected migration pattern in recent times.

The feeling was that wildlife is competing with all of the above commercial activities. Professional hunter Andy Wilkinson²⁸⁸ from Zimbabwe coined the term “politics of despair”. There is no work in the urban areas, so people are coming back and making a living off of the natural resource base in any way they can. Most of the invaders into Southern Maasailand are non-Maasai such as Chaga, Warusha, Warangi and the Wapare (Mbarnoti, *pers. comm.*). This invasion is happening all over Maasailand.

Even the Maasai are turning to farming out of desperation. Lendii (2004) explains how Maasai women in Northern Maasailand, out of desperation, are clear cutting dry forests working for a month to obtain wages that sustain them for a week.

²⁸⁸ Andy Wilkinson, 6 Farnborough Close, P.O. Box Borrowdale, Harare, Zimbabwe, Professional Hunter working in Tanzania and RCA

As described in Chapter 3, pastoralists such as the Maasai and Barabaig, and hunter-gatherers including the Dorobo have been forced to survive on smaller and more confined areas each year. This is especially a problem in what is called the “northern tourism circuit;” the areas of Serengeti, Ngorongoro, Lake Manyara, Tarangire, Arusha and Kilimanjaro. Much of this region, including the protected areas, was once Maasailand (and grazed under nomadic herding practices) or customarily held by other local groups. With the formation of parks and other protected areas, many people were dispossessed of land and resources, including pasture and water, central to their livelihood and well being. These conditions have resulted in considerable human-wildlife conflicts. Keeping traditional migratory routes open between parks and protected areas, which tend to serve as dry season grazing areas, and rainy season dispersal areas, is believed critical to maintaining healthy wildlife and habitat in the parks. Wildlife buffer zones to maintain these corridors and dispersal areas in the form of Wildlife Management Areas (WMAs) with corresponding benefits to local people are considered critical (Shauri & Hitchcock, 1999). As noted, Igoe & Croucher (2001) found that to date in Southern Maasailand, WMAs that in theory should benefit local people, fail to do so miserably, further disenfranchising Maasai from their land and resources, and alienating them from so-called conservation. A key question that remains to be answered is if these “high altitude grasslands” can compete with agriculture, especially wheat, corn/maize needed to feed the ever-growing human populations of East Africa (see Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya), and the spread of commercial farms for seed-bean export (Maliti, 2007).

As for the young Maasai *morani*, they see no future for themselves as pastoralists. After Standard 7 (ages 13-15), the majority leave school (completion of Standard 14/Form 6 would be a high school degree) and work in the tanzanite mines.

Many young Maasai males, including those from Simanjiro, are leaving in hordes for the bright lights of the big cities such as Arusha and Dar es Salaam to find work as *askaris* (watchmen) (Mbarnoti, 2003; 2004; Lendii, 2004) (see Chapter 5. Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya). In both instances, they are poorly paid and most are unable to support a family. Being without an education and seeing little future in the subsistence wages most of them earn, they reinvest what little savings they have back into cattle, even though they know that there is little future in pastoralism. However, they see no alternative solution. Thus, as part of the urban poor, they continue to contribute to the degradation of Tanzania's rangelands. These young men are falling back on a support system, pastoralism, which, as currently practiced, is not sustainable in over-crowded Southern Maasailand (Mbarnoti, 2003). What is the future for these once proud people who feared neither humans nor beasts while wandering the plains of East Africa with their livestock, co-existing in relative harmony with wildlife? Plans are to turn this area into a wildlife management area (WMA) and to develop a land use management plan, which identifies and protects critical wildlife habitat.

However, safari operator Ridge Taylor (*pers. comm.*) is concerned that it may already be too late for a land use plan to conserve these WMAs. Due to administrative subdivision of the area, the hunting block of Loibor Siret will soon be divided in two by a hard top road that will accommodate access by small-scale farmers and poachers. This hunting block could soon become a "paper tiger" with little or no game. In addition, the Maasai already lost the Mukingonaro Game Control Area (GCA) to the Tarangire National Park. There is concern that the Maasai spear many animals, including lion in Loibor Siret, as a form of "revenge killings" because of fear that they may also lose this area to the park, if it is not already being lost to small-scale farmers. Mbarnoti (2004) explains that out of

anger for having been compressed into areas that can no longer sustain them, while given no viable option for a sustainable future, the Maasai are not only spearing wildlife, but also collaborating with poachers seen as

“allies in reducing the number of wildlife as livestock competitors, wildlife being seen as the cause for their loss of land by establishment of protected areas which do not benefit the Maasai. Pastoralists understand that laws are formed and practiced for the interest and benefit of the wildlife management authorities and not from a mutual relationship. They see the laws as biased and marginalizing them”.

In January 2007, lion following wildlife dispersing out of Tarangire National Park attacked the cattle boma in the village of Loibor Siret. This was reported to TANAPA game guards but no action was taken. After the second attack, the village poisoned 16 lions (Mbarnoti, *pers. comm.*). One can be sure this is happening daily, throughout Sub-Saharan Africa. Similarly, Holmern, Nyahongo & Roskaft (2007) found “revenge killings” of carnivores around Serengeti National Park strongly correlating with livestock depredation of livestock, and can be considered a poor response by government, and little or no benefits from trophy hunting reaching local people that might possibly change attitudes.

Thus, unless wildlife can compete with these other commercial activities and it is in the interest of the rural populations to conserve wildlife (e.g., obtaining full user rights both consumptive and non-consumptive in the form of WMAs), wildlife populations will continue to decline at the alarming rate we are seeing and the word going around, “Hunt Tanzania while you can”, may not be too far from the truth.

Since the mid-1980s, Tanzania National Parks (TANAPA), as part of the *Ujirani Mwema* (good neighborliness) program, has established a community conservation service. In collaboration with the African Wildlife Foundation

(AWF)'s Community Conservation Service Center (CCS) in Arusha, a community development program has also been established, based on sharing profits from tourism with the local community (Kangwana & Ole Mako, 1998). According to Barrow, *et al.* (2000), TANAPA has taken ownership of the CCS. However, one must question its effectiveness, given the information in this case study and the devious way in which AWF has dealt with Maasai communities in establishing WMAs (see Section 9.6.3.6, SCP, Tanzania). A major problem with TANAPA is that human activities such as settlement and cultivation, mainly in the surrounding Controlled Hunting Areas (CHAs), are administered by the Wildlife Division of the Ministry of Natural Resources and Tourism (MNRT).

“TANAPA operates in an institutional landscape that does not give it a strong mandate to work outside national parks, even though between 1992 and 1997, US\$ 93,800 was distributed to peripheral communities mainly for schools, health services and clean water” (Kangwana & Ole Mako, 1998).

There are also conflicts between safari operators and eco-tourism operators. Since these Game Control Areas (GCAs) and Open Areas are currently not Wildlife Management Areas (WMAs) where communities can benefit directly from hunting revenue through joint ventures with safari companies, photographic operators have moved in along the eastern borders of the park and made agreements with local communities to disallow hunting, even though the Wildlife Division has awarded hunting contracts to these companies (Taylor, *pers. comm.*). In 1990 and 1993, the communities took in US\$ 16,670 from eco-tourism, which though very little income per year, is 100% more than they get from hunting (Kangwana & Ole Mako, 1998).

Similarities between Southern Maasailand and Loliondo Game Control Area (GCA), Northern Maasailand

Nelson and Ole Makko (2005 *In: Lyman & Child, 2005*) demonstrate a similar conflict between different conservation philosophies in the Loliondo Game Control Area (GCA) of Tanzania, where the village government of Ololosokwan brings in about US\$ 55,000 annually from non-consumptive photographic tourism²⁸⁹ and is reluctant to devolve this authority to a higher level community based organization (CBO) as part of the WMA process that could deprive the village level institution and its 3,500 residents of both power and income. Additionally, there is a lack of trust in the Frankfurt Zoological Society, pushing the WMA process, since they are linked to the removal of Maasai in the creation of the bordering Serengeti National Park, as well as nearby Ngorongoro Conservation Area (NCA), and one can be sure that they are aware of the recent AWF attempts to remove people in creating Southern Maasailand WMAs .

This also appears to be linked to the government holding off on the rapid transformation of game control and Open Areas into WMAs (see 9.6.3.6, SCP, Tanzania). Since communities receive no benefits from hunting, they are leasing their lands across Maasailand to eco-tourism operators. This contravenes the Wildlife Division's Tourist Hunting Regulations of 2000, which do not allow eco-tourism activities in hunting blocks. This is seen as a power struggle between national and local governments versus rural communities over who benefits from natural resources. It is also an administrative conflict where hunting blocks cut across village lands as declared under the Local Government Act of 1982 and in which village councils can create bylaws to zone and manage their lands (Nelson,

²⁸⁹ In 2002, the village of Ololosokwan earned US\$ 64,287: US\$ 58,866 (92%) from tourism, US\$ 3,000 from hunting, US\$ 832 from district council funds and US\$ 1,586 from other. Although not a WMA, a member of the royal family from the United Arab Emirates, under the name of Orthello Corporation that has the Loliondo Game Control area, pays each of the six villages in this area an annual fee (Nelson & Makko, 2005 *In: Lyman & Child, 2005*).

2004; Nelson & Makko, 2005 *In: Lyman & Child, 2005*). While in the case of Taylor (*pers. comm.*), eco-tourism impacted his ability to hunt, Nelson (2004) and Nelson and Makko (2005 *In: Lyman & Child, 2005*) also demonstrate that hunting can negatively impact eco-tourism, since many eco-tourism groups avoid coming into areas during the peak-hunting season. In Botswana, safari operators are obliged to have both hunting and eco-tourism lodges. Similarly, in South Africa, dual activities are successfully carried out on both private (e.g., Zulu Nyala Lodge) and public (Pilanesberg and Madikwe Parks) lands. The real issue is not whether this dual use can be successfully undertaken, but who benefits and who controls land use!

9.7.8.3 Need for non-rural livelihood alternatives through industrialization

As demonstrated in Chapter 5 on agriculture and from the benefits/household ratios in most CBNRM schemes (see Section 9.5, SUCCESS OF CBNRM BASED ON CONSUMPTION AND COMMODITY PRODUCTION), the conservation community has to be honest with itself that rural Sub-Saharan Africa has exceeded its carrying capacity for providing a minimal quality of life for the average person. Even if communities obtain the majority of income from safari hunting or eco-tourism as suggested in Section 9.7.6.5, “Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders”, it would not significantly improve livelihoods for most people in rural Sub-Saharan Africa. Take CAMPFIRE as an example. Even if the US\$ 15 million earned over 11 years was tripled to US\$ 45 million, at the household level this would amount to an increase from an average of US\$ 18.60/household in gross revenue to about US\$ 46/household assuming household numbers are static at 95,000 (Section 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa), which we know is not the case as Africa’s population will more than double in 50 years (Chapter 5, Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL

PRODUCTIVITY). In other words, human populations are completely out of balance with Sub-Saharan Africa's natural systems, if the majority of the populace is condemned to live subsistence lifestyles, eking out an existence as itinerant farmers and pastoralists or even trying to earn a living from wildlife. These ways of life are quickly disappearing, as pointed out in Chapter 5 on agriculture and Chapter 6 on boreholes and pastoralism.

We have to be honest with ourselves that CBNRM on its own will not work. Turning 10% or more of each Sub-Saharan Africa country into protected areas is a short-term solution destined to be engulfed by a wave of poverty. Given current rural populations, this creates more poverty as it continues to disenfranchise rural communities and compresses them into already over-populated areas that cannot sustain them, accelerating environmental degradation outside of the protected areas without giving them a viable and sustainable escape route other than into urban slums. This places rural Africans in a downward spiral economically and ecologically that forces them to encroach on and poach in the very natural areas the world wishes to conserve.

CBNRM and the creation of protected areas can be part of the solution only if the majority of the wealth from these areas goes to rural community-owned companies and they pay taxes like all companies, but even this on its own will fail! Such paradigm shifts must fit into a larger plan for the subcontinent, which among other things must relieve pressure on the rural resource base.

Yes, Africa has exceeded its carrying capacity to support people living traditional lifestyles, like it or not. If tomorrow, Europeans and Americans decided that instead of being mostly urban, the majority of the population should return to the soil, they would be faced with a similar problem: not enough land or other resources.

Hara (2004 *In: Fabricius, et al.*, 2004) explains how IMF/World Bank structural adjustment policies (SAPs) resulted in the collapse of local manufacturing industries and the shrinking of the manufacturing sector, forcing people to turn back to living directly off of the natural resource base in Malawi, especially the fisheries (see Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”). This placed undue pressure on the resource base and made the co-management of fisheries between government and the fisher community very difficult. Hara (2004 *In: Fabricius, et al.*, 2004) explains that the success of limiting access to a resource will depend on the general economy acting as a sink of excess labor. As long as employment in other economic sectors remains low and living directly off of natural resources (e.g., soil, wildlife, fisheries, forest and non-forest products) remains the main source of livelihoods, as opposed to transformed natural resources in industry and agro-industry, attempts to assure the sustainable use of resources will be difficult and co-management or sustainable management through devolution of authority to rural communities is unlikely to be successful. As discussed in Chapter 5 on agriculture, Sub-Saharan Africa is stuck in “Phase I”, where too many people are directly dependent on living directly from the soil and other resources. Given the population explosion of the 20th century and the fact that the current population is expected to more than double again by 2050, conservation, be it CBNRM or fortress conservation, is doomed to failure on its own.

What this means is that Africa must industrialize and urbanize and that these processes must be part and parcel of the “big picture” conservation and development plans. Like it or not, the romantic days of the Maasai *morani* walking fiercely across the African plains in his red robe and spear or the Bushmen stalking gemsbok and eland with their poisoned tipped arrows are on their way out. While a small portion of individuals within these cultures will be able to continue leading these traditional lifestyles, if they so choose, there is not enough land nor enough wildlife, pasture, soil, fish or timber for the vast majority

of Sub-Saharan Africans to sustainably live from as in the past; not without destroying the land, its resources, and eventually themselves, which is happening as we speak. The same happened in America. The principal author's mother had 11 brothers and sisters who grew up on a farm in the Appalachian Mountains of Maryland. One sibling was able to farm full time, two farmed part time and the remaining eight earned a living in a suburban environment. The principal author has over 33 first cousins and only one farms full time, the rest being doctors, lawyers, nurses, teachers, etc. Sub-Saharan Africa will have to go through this same evolution if its natural systems are to survive and its people are to have a viable future.

Most of the youth in Africa realize that the future in these rural areas is bleak. The young from all over Africa are “speaking with their feet”, heading to the big cities, many to the promised land, industrialized South Africa, which is being overwhelmed with illegal immigrants and an unimaginable level of crime since the “have-nots” are the majority and increasing in leaps and bounds (see Chapter 5, Section 5.7.5, Food Security and Urbanization in Sub-Saharan Africa and Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife, Impact Of Land Reform On Regional Economies). In September 2003, the principal author hosted the Senegalese national shooting team at his home, while they were in South Africa for the African Championships. Dakar is a Peninsula, so traffic bottlenecks as it enters the capital. It was explained that the problem of immigration from the rural areas is orders of magnitude greater than when the principal author was there in the mid-1970s until the late 1980s. Environmental conditions in the rural areas, as discussed in Chapters 5 and 6, have deteriorated and the youth are heading to the bright lights of the big city, no longer being prepared to tolerate groveling in soils, which no longer produce.

Similarly, the Maasai from Kenya are giving up traditional pastoralism for life in the cities as *askaris* or selling tanzanite; there is just not enough land for them all to have cattle. About four years ago on a trip to Tanzania, the principal author sat in a plane half full with illegal Tanzanian males being returned by South African immigration officials. The principal author experienced the same back in 1974 in El Salvador, the most populated country in the Americas, when a young worker at the fish culture station said,

“We have a saying. When the ship sinks the rats will swim, and I am getting the hell out of here. I am going to the ‘promised land’ - your country, where I can share a room with 5-10 people and make a US\$ 1.25 (today US\$ 5-7) an hour instead of a day. I will send money home and my family will be prosperous. The beautiful thing about your country (like South Africa) is if I get caught, America will give me a free plane ride home to visit my family. I will stay there for a few months on vacation and then return. I mean, what have I to lose”.

Europe faces similar uncontrolled immigration from its neighboring African continent due to failed economies and failed states in Sub-Saharan Africa.

South Africa wake-up! In a continuation of a letter from a Tshwane University graduate in nature conservation handpicked by CAMPFIRE and then residing in Chiredzi, Zimbabwe with a collapsed economy as a result of the radical land reform beginning in 2000 (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife) he wrote,

“Due to the situation I am in, I sometimes think of crossing the border to RSA, hoping that I may get employed as a laborer to sustain my life because I am currently in danger...I cannot hide my desperation to you because doing so is the same as killing myself” (Steyn, 2005).

Mr. Steyn is back at Tshwane University in 2007, studying for a B-Tech in nature conservation. His plans, for the moment, like many Zimbabweans, are to sneak his wife and child into South Africa and remain there until there is regime change!

One can be assured that there is a direct relationship between failed economies/states and declining wildlife numbers on the subcontinent.

While this rural-urban immigration probably needs to be encouraged, most of the youth are improperly trained to be easily absorbed into an urban environment. Additionally, the urban settings in Africa have neither the jobs nor the infrastructure (e.g., adequate homes, sewage, water, electricity, etc.) to provide a decent quality of life for these rural immigrants to Africa's big cities. That is why, as discussed under "politics of despair", many youth are returning to the rural areas, enough anyway to cause concern for the sustainable management of natural resources. They had hoped that the streets in the big cities would be paved with gold but they were not, at least not for the uneducated majority and in most cases even the educated minority! Many stay as hangers on, but many return to their rural homes and become part of the problem, mining the remainder of Africa's resources.

Africa, you have to stop allowing your raw products to be shipped overseas where the added value of transformation is obtained and the processed products are then shipped back and sold to you at higher prices than they were purchased. Africa, wake up! The foreign aid given to you is orders of magnitude below what you can get from urbanizing, industrializing and transforming your continent, as did Europe and America in the 20th century. It is your only hope for your economies, your people and your natural resources. This is discussed in greater detail in the chapters on foreign aid, structural adjustment (SAP) and the private sector, Chapters 11, 12 and 13, respectively.

Up until now, there are two main sets of resources that the West has wanted out of Africa, 1) minerals (petroleum, gold, cobalt, COLTAN, diamonds, bauxite, platinum, etc.) and 2) the experience of “Wild Africa” - the Big 5 (elephant, lion, leopard, rhino and buffalo) and the wide open empty spaces of the continent, either through hunting or eco-tourism. The minerals have tended to be taken out raw and the added value of transformation obtained in the industrialized world.

Even with tourism and safari hunting, because the vast majority of the companies are expatriate-owned and operated, a high percentage of the economic benefits from safari hunting remain “offshore”, never touching the soils of Africa. Africa’s parks and hunting blocks have become a playground for the Western elite who spend a couple weeks every few years to experience primeval Africa, escaping back to their air-conditioning, microwaves, computers and big-screen TVs, while the quality of life of most Africans goes nowhere but down.

While wildlife linked to CBNRM programs may be able to serve as a catalyst for development by providing healthy well-educated children, if the West wants to continue to experience “Wild Africa” and if the international conservation community as well as African states wish to see the biodiversity of the continent maintained, then the West will have to change its approach to dealing with Africa. Elimination of policies that negatively impact trade and the industrialization process in Sub-Saharan Africa such as IMF and World Bank structural adjustment policies (SAPs), as well as control of world commodity prices to the advantage of the West, agricultural subsidies, food and product dumping, protected markets, tariff controls and import quotas, etc. will become critical to the future of the continent, its people and their wildlife. Until the West’s approach to dealing with Africa is “win-win”, America and Europe, do not count on your grandchildren

seeing wild animals in Africa; though maybe they would in future be able to do so on an exotic game ranch/farm in Texas!

Most importantly, the West will have to agree to begin helping Africa to industrialize, to transform raw products in Africa, to pull people back into the urban centers and to begin creating an educated middleclass, even among the blue collar workers. Rural Africa cannot maintain its wildlife habitat, its biodiversity and its “wildness” unless the West helps it move in the same direction that it has evolved. Thus, conservation on its own fails and CBNRM as one aspect of conservation falls flat on its face. It must be part of a bigger plan for each country and fit into a bigger picture for the continent, linking into urbanization and industrialization, training in intensive natural resources management and empowerment of rural communities to sustainably manage their own resources along with concurrent benefits.

9.7.9 Donor and NGO Dependency Counter Productive to CBNRM

“There is growing evidence supported by this study that shows how some of the larger regional programs (such as the USAID - NRMP) may achieve results at a policy and national institutional level but tend not to be as successful at district and sub-district level. The larger programs with their rigid structures, annual work plans, semi-annual reports and log frames are not adaptable to community institutions and time scales” (IUCN/SASUSG, 1997).

In a number of cases, CBNRM projects have become too top heavy and donor dependent and tend to collapse when the donors pull out (Katerere & Chikoku, 2002 *In:* WSP, 2002). CAMPFIRE and ADMADE have suffered from donor dependency. Jones and Murphree (2004 *In:* Child, B., 2004a) state that very often, national associations, usually donor funded as in Namibia, Zimbabwe and Botswana, become another layer of bureaucracy on the CBNRM scene. They do

not necessarily represent the needed constituencies (e.g., producer communities) but are very good at absorbing much of the donor funding.

Where power lies with external agents such as governments, donors or NGOs, rural communities tend to be weak and unable to function on their own, taking away from the sustainability of such. To be effective, the role of NGOs, researchers and governments towards rural communities should be facilitative,

“invited rather than imposed, directed rather than directive and facilitative rather than manipulative” (Jones & Murphree, 2004 *In: Child, B.*, 2004a).

The conditions for donor driven community conservation are likely to be strong where donor experts and domestic constituents are strongly attached to them. Community conservation has been formulated and disseminated at numerous international meetings, applied widely and rapidly in Africa by NGOs and international aid donors such as USAID, often developed and implemented by particular “champions”, and reported on positively in television programs beamed around the world. In particular, Sub-Saharan Africa’s dependence on foreign aid and the expatriate consultants and experts this supports has made it the world region in which exogenous ideas about “what to do” hold the greatest influence. Conditions for the rapid transfer and acceptance of community conservation at the policy level in most Sub-Saharan African countries have been strong over the last decade (Adams & Hulme, 1998) (Table 9.18).

Table 9.18: Conditions in Sub-Saharan Africa supporting the development of CBNRM

Factor (a)	Summary of the Situation in Africa
1. Donor experts & domestic constituencies are attached to the narrative	1. Key donor countries (USA & UK) adopted a community conservation approach & this influenced their “experts” overseas. Conferences (Arlie 1993, Sunningdale 1996, Istanbul 1997) financed by official donors & NGOs helped to transmit the idea of community conservation. Large numbers of leisure-time conservationists in such countries learned to support the new narrative
2. When there is political, strategic or moral pressures on donors to act quickly.	2. Media accounts of the imminent extinction of the gorilla, African elephant & rhino prompted donors to act rapidly. Where states emerged from civil wars (Ethiopia, Uganda, Mozambique, Angola) there was an urgent need to save ‘the remnants’ of the conservation estate. Crises narratives (Roe 1995) allow foreign ‘techno-managerial elite’s to shape policy & action on the African environment.
3. When there has been little technical or socio-economic research locally	3. Despite the wealth of data on the zoology of charismatic species in Africa research on the ecology of Africa & on human-wildlife interaction remains in its infancy
4. When a recipient country relies heavily on expatriate experts for advice.	4. Many Africa countries were more reliant on foreign advisors in the early 1990s than they were at independence (Berg, 1993). This relates to specific advice on conservation & broader advice about the policy & institutional frameworks that countries should adopt.
5. When a recipient country relies heavily on foreign assistance	Sub-Saharan Africa is the most aid dependent region in the World. In 1990 foreign assistance, as a percent of GNP stood at 66% in Mozambique, 48% in Tanzania, 26% in Malawi, 18% in Uganda, 19% in Mali, 11% in Kenya, 14% in Zambia (World Bank, 1992, pp 256-7). The setting up of Global Environmental Fund (GEF) & specialist funds (e.g. USAID) post Rio has led to a flush of external funding for conservation projects in Africa. The idea of “Sustainable development” has also meant that international conservation NGOs have gained influence (and control) over some development funds.
6. When the recipient government is weak or authoritarian (or both)	Over the period 1960-1995 there have been frequent coups in African states. Where this has not occurred, then commonly, authoritarian regimes have held power (e.g., Kenya, Zaire, Malawi). Such regimes have been weak in terms of their ability to meet the needs of their people.
a. From Hoben (1995) b. Fascinatingly the country in Africa which has developed an indigenous model of community conservation, Zimbabwe, had an aid dependence (against GNP) of only 5 % in 1990 (World Bank, 1992, pp. 256-257).	
Note: Arlie, Berg, Sunningdale, Istanbul & World Bank not provided in References of Adams & Hulme (1998)	
Source: Adams & Hulme (1998) with permission, Institute for Development Policy and Management (IDPM), University of Manchester.	

Donors and their allied NGOs, which feed off the donor money, have tended to praise the success of CBNRM. This has been described as “project bias”, whereby successive evaluations of a region or program look repeatedly at the same projects and one another’s reports without properly questioning the nature of change on the ground. This leads to the narrowing of possible lessons that policy-makers and researchers can learn and constrains creativity and innovation (Adams & Hulme, 1998).

It might better be described as “not biting the hand that feeds you”, NGOs and consultants being notorious for telling the donor exactly what they want to hear in a bureaucratic environment where success is based on how much money one moves and not the actual outcome of a project. A positive evaluation that promotes a bureaucrat’s career can result in renewed or new contracts for the consultant, consulting firm or NGO undertaking the evaluation. A negative evaluation can result in the door being shut for future work with the donor.

Another major problem with donor driven CBNRM is that donor funding runs in three to five year cycles. Development in general has been hamstrung by such cycles, very often bringing to a screeching halt processes, which need a much longer duration to become “institutionalized” or to take root.

“Not uncommonly project designers are compromised by donor pressures for results and at the planning stage set objectives for 3 or 5 year projects that they know will take 10 or 20 years to achieve” (Adams & Hulme, 1998).

This, combined with a lack of adequate land and resource tenure, forces communities into short-term planning horizons for the use of wildlife and other resources that are part of long-term ecological processes (Jones & Murphree, 2004 *In: Child, B., 2004a*). Thus, the myth of CBNRM, as is the myth of “Wild Africa”, is perpetuated over and over again. Adams and Hulme (1998) go on to

say that the positive impacts of integrated conservation and development projects (ICDPs), another way of packaging CBNRM or community conservation,

“on local economies are typically transient and dependent on the maintenance of foreign aid flows”

(see Chapter 11), especially when much of the aid goes into supporting top-heavy umbrella associations as described above.

Murombedzi (2003 *In: Adams & Mulligan, 2003*) believes that CBNRM, as practiced today in Southern Africa’s former settler colonies (Namibia, South Africa, Zimbabwe, Zambia and Mozambique), is a convenient intervention that allows the state to extend its control over certain economically and financially valuable resources (wildlife), while appearing to empower “local communities” regarding control of “their resources”. It can even be argued that the governments and private sector tour and safari operators use CBNRM as a political ploy to maintain their economic dominance in Africa’s natural areas at the expense of rural communities, who gain a pittance of the actual value from these natural systems (see Section 9.7.6.5, Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders). The principal author, once had a high level personality in CBNRM tell him, “leave the safari hunting for white Africans. It’s one of the few economic sectors they control, where a person with minimum education can find a career”. This is a form of “economic Apartheid”, where a few elites benefit to the disadvantage of the majority. Meanwhile, the West, which looks at CBNRM at a superficial ideological level, jumps on the bandwagon in full support and the myth goes on while rural Africans become poorer, habitat degrades and wildlife populations dwindle.

Thus, the local community also foregoes the majority of benefits derived from this exclusion, mostly in the form of revenue, since after governments and the

private sector take their shares, little is left for people at the local level. At the level of households, these benefits tend to be insignificant (LWAG/DFID, 2002; Murombedzi, 2003 *In: Adams & Mulligan 2003*), in many cases households losing more than they gain by giving up access to the conservation area and its resources (see Section 9.7.6, Getting the Economics Right).

Likewise, NGOs (both local and international), who make a good living off the donor handouts, which often drive these programs, tend to reflect and then impose Western attitudes and value systems of conservation on these rural constituencies. To a greater or lesser degree, these same critiques apply across most of the continent from Botswana to Tanzania to Cameroon. A key point that Murombedzi (2003 *In: Adams & Mulligan*) makes is that

“communities do not have the right to use wildlife, only the right to benefit from the use of wildlife by others”

with no attempt at identifying ways by which communities manage communal resources (e.g., grazing, wildlife, fisheries, etc.). As a result, Murombedzi found that most local people still see wildlife as belonging to national government and/or local government, depending on the program.

Murombedzi (2003 *In: Adams & Mulligan, 2003*) goes on to say that CBNRM disguises the real dilemma faced by the state, the contradictions of the dualistic nature of colonial property rights; large areas of privately owned white property on the best agricultural lands with large compressed black populations on per capita small over-crowded marginal agricultural lands, often in low rainfall areas.

This is compounded from pressures by IUCN to place 10% of each country's territory in parks and protected areas (see Chapter 11, Section 11.10.6 Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers), exclusion zones resulting in further compression and marginalization of rural Africans as currently practiced. Thus,

CBNRM provides property rights to rural communities assigned to them by colonial history, without questioning the legitimacy of or redressing the historical past, strengthening and reinforcing racial and class patterns of access to and use of natural resources. CBNRM tends to strengthen local government/traditional authority as redefined by colonial indirect rule (Murombedzi, 2003 *In: Adams & Mulligan, 2003*), that is chiefs and/or local governments often salaried by central government whose allegiances are to the bureaucracy and ruling party as opposed to their supposed constituency, the rural people living among wildlife (see Chapter 3, Section 3.1.4.1 Francophone colonial Africa, Indirect Rule).

CBNRM through foreign aided donor support thus places communities in a compromised “patronizing relationship” with governments, NGOs and mostly white safari and tourism operators, many of whom are remnants of the colonial past and to whom the community must forego its traditional rights of access to the area (Murombedzi, 2003 *In: Adams & Mulligan, 2003*) and their direct use of resources such as wildlife, honey, timber, fish, etc. This helps create the “myth of wild Africa”, free of people and their livestock, something very rare in Sub-Saharan Africa prior to the arrival of white people, where Africans had co-evolved with wildlife and were integral in maintaining the savanna landscape – as much a part of the savanna ecology as buffalo and elephant (see Chapter 1, Section 1.3, CO-EVOLUTION OF HUMANS AND WILDLIFE IN SUB-SAHARAN AFRICA). The historical reasons for the domination of the safari industry by whites originate in the appropriation of rights from local populations by the colonial state (Murombedzi, 2003 *In: Adams & Mulligan, 2003*) (see Chapter 3, Section 3.4, DEVELOPMENT OF AN ENVIRONMENTAL CONSCIENCE AND EXCLUSION OF AFRICANS FROM LEGALLY ACCESSING WILDLIFE). This appropriation of rights through the expropriation of natural resources and land still exists across the continent to this day. These expropriated areas and their wildlife then become the exclusive playgrounds of

wealthy, mostly European and American, clients. Protected areas are for everyone but the rural people living around and in some cases within them (e.g., game controlled areas in Tanzania, hunting blocks in Zambia, hunting blocks and national parks in general).

9.7.9.1 CAMPFIRE, Zimbabwe

Hasler (1999 *In: Roe & Jack, 2001*) argues that CAMPFIRE, rather than a true community empowerment program, has like ADMADE become highly politicized nationally and internationally. It suffers from political patronage, as is described in some detail in Chapter 11, which presents a hindrance to installing Western models of democracy in Africa.

“As a socio-political movement, there are a number of key loci of power and decision-making. At an international level, donor agencies, the United States Congress (influenced by the public and lobby groups), CITES and international wildlife lobby groups (see Chapter 10) all have an influence on CAMPFIRE. Nationally, policy and implementation decisions are central to the development of the program, since it is there that devolution decisions lie. The CAMPFIRE Collaborative Group²⁹⁰, designers and implementers of the program, act as an interface between communities and donors, policy makers and politicians, and they also command some power over outcomes, which may be in direct opposition to the government’s. Locally, Rural District Councils (RDCs) and District Administration also influence outcomes, and there are allegations of corruption and embezzlement of funds. Within communities, power is not diffuse, and often sits with leadership: elites, chiefs, democratically elected authorities such as the councilors or Village Development Committee members, or religious functionaries. Lines of patronage then, run from the local to the national level, with the ruling ZANU-PF government attempting to impose centralized control on remote villages and peoples” (Hasler, 1999 *In: Roe & Jack, 2001*).

²⁹⁰ CAMPFIRE Collaborative Group consists of CAMPFIRE Association representing rural district councils, Wildlife Department, Center For Applied Social Sciences (CASS) at University of Zimbabwe, WWF, African Resources Trust, Zimbabwe Trust.

Back in the late 1980s, as the Cold War began to wane, there was pressure from Jesse Helms and Pat Buchanan to shut down the U.S. Agency for International Development (USAID) as an instrument of the Cold War that had outlived its usefulness. USAID scrambled to show success stories from its interventions in developing world countries. There were few and/or none to be found, as development has never been the goal of Western donors (see Chapter 11 on foreign aid). They stumbled on to CAMPFIRE, saw that it was a success story, and quickly took ownership of it by throwing large sums of money into the program.

The intervention by USAID resulted in the CAMPFIRE Association of Rural District Councils (RDCs) (local government, not producer communities) becoming more dependent on U.S. foreign aid (American taxpayers' dollars) than money from wildlife. The CAMPFIRE Association seemed to spend more time playing international politics than meeting the direct needs of its constituency, the rural communities. The pro-sustainable use group CAMPFIRE Association has been a key player on the international stage at such forums as the Convention on International Trade in Endangered Species (CITES) and the Convention on Biological Diversity (CBD) by turning the international debate over sustainable use versus preservation into a community issue of empowerment and economic development for which the animal rights have little rebuttal other than to try and discredit such programs (Duffy, 2000). The CAMPFIRE Association does not really represent rural producer communities, nor does it really need them since it has lived off Western donor money, turning it into a top-heavy organization, like many NGOs feeding at the donor trough. Without USAID intervention, would the evolution to representation of producer communities have happened any quicker – today this is being talked about?

As USAID, after spending \$50 million over about 11 years (1989-2000) (Sparrow, *pers. comm.*), pulls out at the beginning of the 21st century, the CAMPFIRE Association will go through major withdrawal symptoms (e.g. streamlining its personnel) and may not survive, unless it can demonstrate to Rural District Councils (RDCs)/communities that it is providing them with a service and that they should spend some of their profits from wildlife to keep the CAMPFIRE Association going. Fabricius, *et al.* (2001) place the total amount of donor funding to CAMPFIRE at US\$ 44.1 million and also conclude that the program is over-bureaucratized at the district (RDCs – local government) and national (CAMPFIRE Association) levels, resulting in a failure to devolve meaningful rights of ownership to the ward and village levels. Barrow, *et al.* (2000) note in East Africa that heavy donor dependency and funding

“has resulted in high costs and high infrastructure dependent community conservation structures and programs. This perhaps was inevitable, given the nature of donor funded projects, but it means that conservation authorities must adapt these structures to the more modest financial resources available internally”.

Already CAMPFIRE appears to be in trouble, as its constituency, “Rural District Councils (RDCs)”, is refusing to provide CAMPFIRE with support funds since the association provides them no services (Sparrow, *pers. comm.*). Unfortunately, many of the services, which CAMPFIRE should be providing to its constituency, are being provided by other NGOs such as WWF (wildlife monitoring and quota setting) and ZIMTRUST (institutional development); both of whom had an important role to play initially, but who should slowly hand over much of these responsibilities to the CAMPFIRE Association. Unfortunately, by making themselves indispensable, they have lived off of USAID/donor funding and are reluctant to devolve these responsibilities to the CAMPFIRE Association, these roles being their *raisons d'être* while they feed at the donor trough. The CAMPFIRE Association planned further devolution to the village level until the

political turmoil of the early 2000s set this process backwards, likely for many years.

9.7.9.2 LIFE, Namibia, Nyae Nyae Conservancy

Habits born out of a legacy of marginalization have fostered a culture of dependency, which has resulted in expectations for outsiders to take the lead, which can contribute to passivity and reluctance to be proactive (Berger, 2003). Too often, donors, both at the local and national levels, have created dependency. This must be avoided at all costs.

9.8 THE WAY FORWARD – CONSERVATION BY THE PEOPLE – STAGE 4 EQUALS DEVOLUTION

The International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU) World Commission on Protected Areas (WCPA) and the WWF have recognized that (Beltran, 2000):

- “Protected areas will survive only if they are seen to be of value, in the widest sense, to the nation as a whole and to local people in particular.
- The rights of indigenous and other traditional peoples inhabiting protected areas must be respected by promoting and allowing full participation in co-management of resources and in a way that would not affect or undermine the objectives for the protected area as set out in its management plan.
- Knowledge, innovations and practices of indigenous and other traditional peoples have much to contribute to the management of protected areas.
- Governments and protected area managers should incorporate customary and indigenous tenure and resource use and control systems, as a means of enhancing biodiversity conservation”.

These objectives are laudable given the history of conservation in Sub-Saharan Africa. However, a key question must be asked, “Who developed the management plan”? Was it developed by expatriates and government bureaucrats and/or undertaken in collaboration with rural peripheral communities or communities living within these protected areas? What are the biases in developing the plan for utilization of the protected area? There is still a tendency to move people out of protected areas and to ignore their traditional resource uses and management systems to create exclusion zones. Too often, while “community participation” is spoken of, the rural communities, while they may have a say, take a back seat to other stakeholders and more “Sherwood Forests” are created instead of integrating the rural communities into the management of the protected area and more importantly management of its resources (see Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource).

Jones and Murphree (2004 *In:* Child, B., 2004a) conclude that policy and legislative changes

“do not go far enough in removing bureaucratic hurdles that increase transaction costs; they have not gone far enough in giving full management authority to resource users; they have not gone far enough in treating wildlife as a competitive form of land use; and they have not gone far enough in providing local residents with secure and exclusive rights over their land” and resources.

In simple terms, devolution of authority over wildlife and land to local communities to own, manage and benefit from it is far from having been achieved. The following case studies are trying to move in this direction – the ultimate step in empowerment and the only hope for Sub-Saharan Africa’s natural systems to survive the long-term.

9.8.1 Why Conservation by the People Makes Sense

In most of Africa, the state has limited resources to manage “national common property” as a means of conserving vulnerable species, critical and/or unique habitat. Giving the prevailing economic conditions in Africa, this implies that the park estate must necessarily be very small, concentrating state managerial resources (Murphree, 2001 *In: Baldus, et al.*, 2001).

Speaking of natural forest management, although this equally applies to wildlife, fisheries, pasture and other natural resources, Messer (2001) states,

“However, increasingly, it is being recognized that many indigenous forest management systems have been, and, fortunately, often still are, quite ingenious at contributing to preserve the natural environment whilst at the same time making a living out of that same resource base. What is at stake here is not so much the content but the process of policy formulation, the nature of political participation and the legitimate desire of forest users to manage the resources from which they derive part or all of their livelihoods. Needless to say, monitoring this type of ‘qualitative’ issue is not easy, and from the moment a decision is taken on devolving power to anybody, checks and balances should be envisaged to restrict their authority if necessary and to allow for complaints on the part of the local populations to be voiced and addressed”.

In other words, the role of government changes from one of conflict as a policeman to collaboration, setting the rules, monitoring to assure they are agreed on, making sure the community abides by any agreements and extension.

9.8.2 Guidelines for Success

The 1999 African Advisory Board²⁹¹ (AAB) developed “Community Guidelines”, which set the roles that each stakeholder has in CBNRM. Each country was asked to consider adapting the “Community Guidelines” to its own socio-economic and political realities. Based primarily on the Southern African experience, the AAB came to the conclusions that CBNRM must fulfill the following requirements in order to have “Conservation by the People:”

Similar to the above, Fabricius, *et al.* (2001, *In:* Fabricius, *et al.*, 2004) found that where resources have high unit value, such as mega-fauna, once the beneficiaries are relatively small (less than 100 households) or at densities less than 20 people/km² (IUCN/SASUSG, 1997; Murphree, 1997), the income/household from community-based wildlife management can be relatively high (see Section 9.7.6.4, CBNRM will not create a “middle class” in rural Africa, CAMPFIRE, Zimbabwe). This could also be argued for tropical lowland forests, if the rural community was allowed to obtain the majority of the benefits or even in certain coastal zones, if community-run SCUBA diving and sportfishing was developed. Unfortunately, as described, until now, the majority of the true value of these resources is taken up by outsiders. This must change.

The AAB (1999) determined that the role of government should be: 1) to insure that wildlife and biodiversity are available for future generations, 2) to insure that an appropriate wildlife policy exists, 3) to insure that appropriate monitoring and enforcement are in place, 4) serve as a watchdog, 5) create an enabling environment for community empowerment, 6) create an enabling environment for

²⁹¹ The AAB was a loose confederation of governments, rural communities, sport hunters, professional hunters and safari operators, conservation NGOs, researchers and academic institutions which met once a year to network, discuss common issues associated with the rural hunting areas of Africa and to workshop common problems, sharing group experiences in an attempt to find the way forward. It began in 1995 and ceased to exist at the end of 2001.

community and private sector joint ventures and 7) provide technical support and community capacity building.

COMMUNITY GUIDELINES

- Grass roots approach;
- Devolution of rights to landholders;
- Insure responsibility devolved to lowest level in society that can be performed adequately – household/village level/WARD;
- Trust/conservancy should consist of 200-250 households maximum in order to allow regular communication;
- Close link between production (wildlife) and benefits in order for community to realize importance of protecting wildlife;
- Security of tenure to resource user (i.e., safari operator and community);
- All benefits of wildlife go to landowners and they determine how they spend or disperse benefits;
- Community decides how to use quota (e.g., sell to safari operator, split setting aside portion for traditional hunter, photo tourism only, and/or combination);
- Incentives to invest – long-term tenure for safari operators – “joint venture partner;”
- Incentives to conserve wildlife – benefits destined for communities – go directly from joint venture partner to community;
- Right of community to independently select joint venture partner;
- Accountability – community held to certain responsibilities for right to benefit;
- Transparency – in distribution of benefits – external audit;
- Wildlife benefits to government from income tax of community and safari operator (i.e., same as other commercial businesses); and
- Hunting quotas and other management decision-making based on scientific approach – appropriate management data collected by safari operator/community.

Source: AAB (1999)

According to Schlager and Ostrom (1992), five basic rights are most relevant for the use of common resources. These are defined as follows:

- Access—the right to enter a defined physical area and enjoy non-subtractive benefits (for example, hike, canoe or sit in the sun);
- Withdrawal—the right to obtain resource units or products of a resource system (for example, catch fish or divert water);
- Management—the right to regulate internal use patterns and transform the resource by making improvements;

- Exclusion—the right to determine who will have access rights and withdrawal rights and how those rights may be transferred; and
- Alienation—the right to sell or lease management and exclusion rights.

An examination of CBNRM programs in eight countries indicates that success depends on meeting most of the following criteria (Child, 1995):

- Producers, managers and beneficiaries should be the same people;
- Producer communities should be small enough for all households to participate in the program;
- Bodies representing the community should be accountable to the community;
- Functions should be developed to the lowest level of social organization at which they can be performed properly;
- There must be a close link between production and benefits;
- Producer communities must be able to allocate their earnings as they wish;
- All marketing should be open and competitive;
- Wild resources should not be taxed more heavily than other resources;
- Communities should not over extend themselves;
- Government is the ultimate authority for wild resources;
- Developing community management skills and systems is vital; and
- CBNRM represents cooperation between local people and government.

Murphree (1998b *In: Fabricius, et al., 2001*) outlined the following principles necessary for success:

- Effective management of natural resources is best achieved by giving it focused value for those who live with them;
- Local people are the real managers of the environment, and they should derive benefits from natural resources that exceed cost;
- Differential inputs must result in different benefits;
- The size of the benefit should be proportional to the input or cost of looking after wildlife;
- There must be a positive correlation between quality of management and magnitude of benefit;

- Good management of resources should be rewarded by matching benefit;
- The structures which preside over the sharing of benefits should be the same institutions which are responsible for management of the resources;
- The unit of proprietorship should be as small as practicable, within ecological and socio-political constraints; and
- Small institutions increase the efficiency and willingness to take responsibility and decrease the likelihood for corruption. They enhance a sense of ‘collective identify’ and make it more practicable to enforce rules.

Ostrom (1990 *In: Fabricius, et al.*, 2001) laid out the following principles for long lasting communal institutions:

- **Clearly Defined Boundaries:** Individuals or households who have rights to use resources must be clearly defined, as must the boundaries of the resource itself;
- **Rules Governing Use Or Provision Of The Resource Must Be Appropriate To Local Conditions:** Rules for using the resource or providing it to resource users, such as restricting time, place, technology and how much can be used, must be appropriate to the resource itself, including availability;
- **Collective-Choice Arrangements:** Most individuals affected by the operational rules can participate in changing the rules;
- **Monitoring:** Monitors of the rules and the use of the resource are either resource users themselves or accountable to other users;
- **Graduated Sanctions:** Resource users who break the rules are likely to face various degrees of punishment, depending on the seriousness and context of the offence. Punishments are decided by the other resource users, by officials accountable to them, or by both;
- **Conflict Resolution Mechanisms:** Resource users and their officials have rapid access to low-cost local mechanisms to resolve conflicts among users or between users and officials;
- **Recognition Of Legitimacy:** Government supports, or at least does not challenge, the rights of the resource users to devise their own institutions; and
- **Nested Enterprises** (for Common Property Resources that are part of a larger system): Resource use or provision, monitoring, enforcement, conflict resolution, and governance activities are organized in multiple layers of nested institutions, where rights and responsibilities are clearly defined.

The IUCN/SASUSG (1997) outline a series of incentives they believe need to be initiated by the state, though in essence they are also policies that need to be recognized by the international community for CBNRM to be successful:

- The recognition of wildlife management, not merely as an acceptable form of land use, but rather as a preferred form of land use;
- Co-ordination amongst government agencies responsible for resources to ensure that conflicting agendas are not prejudicing the development of wildlife as a land use;
- The removal of market distortions which favor lower valued land uses (e.g. subsidies to the cattle industry) (see, Chapter 11, Section, 11.7.7.1 Lomé Convention and subsidized beef in Botswana);
- The streamlining of bureaucracy in permit issuance and project approval which acts as a disincentive to the development of the wildlife industry;
- Collaboration and co-operation with NGOs and the private sector in community development based on natural resources;
- The promotion of wildlife populations outside the SPAs (protected areas) through the translocation of breeding nuclei of selected species from SPAs to new initiatives at economical rates;
- The expenditure of government funds on research which will benefit the wildlife industry;
- The defense of wildlife producer communities rights in international treaties such as CITES (see Chapter 10);
- Effective management of natural resources is best achieved by giving the resource a focused value. To determine whether the benefit of managing a resource exceeds the cost, the resource must have a measurable value to the community;
- Differential inputs must result in differential benefits: those communities living with the resource and thus bearing a higher cost should receive higher benefits than those who do not bear the cost;
- There must be a positive correlation between the quality of management and the magnitude of derived benefits: an incentive for good management must reward greater investment in the resource with greater benefits;
- The unit of proprietorship (i.e., who decides ?) should be the same as the unit of production, management and benefit: the group which manages the resource should also form the local management institution; and
- The unit of proprietorship should be as small as practicable: smaller social groups are better at managing themselves and the resource than large anonymous institutions.

These ingredients for success from various groups and individuals are all similar and they all imply devolution to the producer community, which would be a village or group of villages and the user groups within these bodies.

9.8.2.1 Wildlife attributes for success

Roe, *et al.* (2000) identify the following attributes of wildlife for CBNRM to be successful. This could also apply to other natural resources (Roe, *et al.*, 2000):

- **Clear and defensible boundaries:** Wildlife assets are clearly demarcated and agreed on by users. Mobility of wildlife as a “fugitive” resource on which many CBNRM schemes are based is often questioned. Thus, the size of the area must be large enough to house entire resources and/or quotas between areas that share resources must be jointly determined and shared. A proper monitoring program will help define and clarify this issue (see Section, 9.7.7, Inappropriate or No Wildlife Monitoring to Assure Sustainability);
- **Manageable scale:** “Wildlife areas need to be sufficiently large to warrant collective action, yet small enough, given the communication and transportation technology in use, that users can develop accurate knowledge of external boundaries and internal microenvironments;”
- **Relative scarcity:** There is little advantage in organizing in situations where wildlife assets are under-utilized and abundant, while the reverse trends, as over much of Sub-Saharan Africa in the 21st century, encourage organization;
- **Substantial value:** The greater the value of wildlife, the greater the chances of success. The danger is that with this high value, more powerful groups move in at the expense of communities;
- **Relative proximity to communities:** Wildlife needs to be close to the respective beneficiary community, but not so close that the costs outweigh the benefits, such as wildlife becoming problematic on a large scale (e.g., regular elephant raiding of fields or cattle killing by lions), “nor too far” which may lead to there being little interest in investing labor in its management;

- **Predictability and ease of monitoring:** “Reliable information” about the general condition of the wildlife assets must also be accessible at reasonable cost (see Section, 9.7.7, Inappropriate or No Wildlife Monitoring to Assure Sustainability);
- **Seasonality in tune with livelihoods:** Wildlife utilization must dovetail with other livelihood strategies. Traditionally, many hunting seasons coincided with the end of the harvest/agricultural season, but many months into the calving season so that the next year’s crop of wildlife was assured of survival (see Chapter 2, Section 2.1.3, Controlling Access to Wildlife Through the Chief; Section 2.1.5, Mobility as a Means of Managing Natural Resources; Section 2.1.6, Hunting Guilds as a Means of Controlling Access to Wildlife; Section 2.2.2.4, Fishing seasons; Section 2.3.1, Land and Section 2.3.2, Pasture and Water); and
- **Ease of utilization:** Wildlife assets are more easily managed where the mechanics of protection and harvest are simple and affordable.

9.8.2.2 Community attributes for success

Roe, *et al.* (2000) identify the following attributes of communities and community institutions for success:

- **Ability to claim and secure tenure:** Security of land and resource tenure is one of the most critical requirements for success, especially from centralized governments to local communities, so that the latter may take advantage of the resources, while excluding outsiders (see Section 9.7.2.1, Devolution Through Policy Reform, Land and Resource Tenure);
- **Small-scale:** (referring to social not spatial scale): Effective community organization based on personal interaction necessary for group “cohesion” is only possible within relatively small groups;
- **Demand for, and dependence on, wildlife assets:** The greater the demand for wildlife and the more vital people’s livelihoods, the greater the chances of success.
- **Cultural significance of wildlife:** It is important to build on the ties (see Chapter 2) between local people and wildlife that still remain despite the attempts by colonialism and the last 40 years of independence to extinguish them. Stronger ties create a greater likelihood for success;

- **Stakeholder identification and group demarcation:** This refers to the ability to clearly identify and determine stakeholder groups [e.g., traditional groups (hunters, charcoal makers, sawyers, fishermen, honey collectors, traditional herbalists, pastoralists, etc.), government (game/parks departments) and private sector (safari and tour operators)] and negotiate their rights of access – when, where, how, what and how much, so as to minimize conflict;
- **Institutions built on existing tradition:** “Community institutions: social structures, rules, processes and arrangements, are the building blocks of community organization and collective action and so have a major influence on the efficacy of CWM (CBNRM)...Whether CWM (CBNRM) is best ‘housed’ in these old institutions or in new purpose-built institutions is another question. Traditional institutions often play an important role in managing wildlife, and their exclusion from some West and Central African CWM initiatives has undermined these initiatives. Many effective local institutions are highly informal, consisting of regularized practices of particular groups of people rather than a fixed set of rules; they are dynamic and flexible, which may be in contrast to introduced formal organizations. On the other hand traditional institutions are sometimes male-biased and relatively undemocratic, whilst novel institutions may offer groups previously marginalized from decision-making, including women and migrant people, the opportunity to have a say...Experience seems to show that the solution lies with new learning institutions built on solid old foundations”. (see Section 9.7.4, Ignoring Constraints in Institution Building and Section 9.7.4.2, Ignoring Cultural Constraints in Institution Building);
- **Representativeness and legitimacy:** “The distribution of decision-making rights over the wildlife assets needs to be seen as reasonably fair. Making institutions genuinely representative has proven tricky...Legitimacy in the eyes of the community may not stem from the accountability and transparency so much favored by some outsiders. Relatively unaccountable local leaders and procedures may have a firm base of support in some cases”. However, given the history of CBNRM and its failure with regards to financial management, an auditing system by outsiders is highly recommended (see Section 9.7.6.3, Accountability, transparency and the creation of capitalist structures within communal systems);

- **Adaptability and resilience:** The ability of institutions to deal with common problems and adjust local rules of wildlife use in response to changing circumstances is crucial to longevity of initiatives. This is especially true where because of increased human populations relative to the resource base, traditional extensive management systems (see Chapter 2) may need to be integrated into more intensive management systems based on monitoring and limited quotas (see Section 9.7.7, Inappropriate or No Wildlife Monitoring to Assure Sustainability);
- **Effective rules, mutual obligations and sanctions:** “CWM (CBNRM) institutions need rules for their members to abide by. These appear to fall into two groups: 1. Use Rules: restricting time, place, technology or quantity of wildlife units, 2. Provision Rules: requiring labor, materials, and/or money. Such rules need to be appropriate and flexible enough for local conditions”. Rule systems depend on violators being sanctioned appropriate to the seriousness of the offence, either by their peers or by officials accountable to the group;
- **Balance between customary and statutory law:** “...statutory law cannot be overlooked. However, people in rural areas tend to be more familiar with customary rules, regulations and boundaries than with statutory law...Compared to statutory law, customary law is often speedy, binding, known to all, cheap and with flexible sanctions determined by the violator's ability to pay. However, community rules can also be quite severe and can be abused...When fundamental human rights are being violated, or when serious ecological destruction is threatened by community action then statutory law may sometimes be the only option;”
- **Negotiated goals:** CBNRM needs to be “negotiated” among stakeholder groups;
- **Conflict-resolution capability:** Conflict- or dispute-resolution mechanisms are essential both between stakeholders (e.g., government, community and private sector) and within stakeholder groups, especially the community institution linking traditional to modern values and management systems as described above, should serve this function for the community;
- **Equity in distribution of benefits and social justice:** CBNRM requires that community institutions have a system for the equitable distribution of benefits and that this be democratically determined, transparent and accountable;
- **Ability to negotiate with neighbors:** Communities should be able to negotiate with neighboring communities to resolve conflict over access to and use of resources, boundaries, etc.;

- **Political efficacy and space to build community-government relationships:** “Communities (often) lack the resources to tackle ecological issues at a regional scale, and in many places have lost their traditional ethos and institutions. Government agencies dealing with conservation lack the necessary micro-knowledge, on the spot human-power, or even the necessary mandate when other agencies over-rule them. Many state roles remain critical, such as resolution of disputes, which cannot be tackled at the local level; legal and administrative back-up of community efforts; channeling assistance from supporters; and acting as a buffer against exploitative outsiders...Stable community-government relationships are more likely where village institutional structures are strong. This is especially the case if these structures are well-established and the government institutions have come to terms with being confronted with a powerful local institution;”
- **Capacity for layered alliances:** To avoid exacerbating community divisions, “layered alliances” (Agarwal, 1997 *In: Roe, et al., 2000*) may be needed, such as central government retaining overall responsibility for the sustainable use of wildlife resources, monitoring, enforcement and internal activities of the conservancies (Jones, 1999b *In: Roe, et al., 2000*) though the long-term goal has to be to train individuals at the tertiary level and plant them back into these conservancies so that full devolution may take place. Within communal conservancies, certain resources may need to be managed by a group of conservancies over a larger space than an individual conservancy, while certain management activities will need to take place at lower levels than the conservancy, such as at the village, user group or even household level. The system must be flexible enough to allow these nested layers of decision-making, authority and resource use to develop over time (Jones, 1999b *In: Roe, et al., 2000*); and
- **Confidence to coordinate external institutions:** With time and individuals from the community receiving appropriate training and then experience representing the community, they will be capable of standing up to and negotiating with both the government and private sector to assure that both their rights of access are assured and that they can negotiate for a rightful share of benefits accrued from the sustainable exploitation and marketing of their resources.

9.8.2.3 Human capital, skills and knowledge

Roe, *et al.* (2000) identified the following as critical to the success of CBNRM:

- **Balance of 'scientific' and indigenous knowledge:** “Traditional ecological knowledge (TEK) and practices often comprise a complex and dynamic mix of old and new, theoretical and practical. Such knowledge incorporates information, attitudes, values and skills and derives its legitimacy and strength from being embedded in the cultural and political milieu of the community. However, for many years TEK has been largely ignored by conservation managers in favor of modern 'scientific' knowledge. Recently, however, TEK has been increasingly recognized as a valid component of resource management...CWM initiatives that build on a combination of TEK and 'scientific' knowledge can result in increased acceptance by both communities and conservationists and mutual understanding;”
- **Versatile leadership:** “Even where efforts are widely shared within a community, one or more charismatic, multi-faceted leaders usually play key roles as catalyst, conflict resolver, or link between community and outside world;” and
- **Numeracy and literacy:** Numeracy and literacy are important skills if communities are to enter meaningful negotiations with the private sector and other external agencies; for example, when agreeing hunting concessions, drawing up contracts for joint venture enterprises or supplying wildlife resources to a particular market.

As noted in Section 9.7.5, Lack of Technical and Management Skills, the authors do not believe that CBNRM goes far enough, if in reality there are aspirations that one day communities will stand on their own two feet. Workshops and short courses are not enough. Selected youth, the “bright lights” from the community, need to be identified and sent off for university training in a variety of skills, from wildlife and range management to business, marketing, accounting, while others need to be apprenticed as professional hunters and tour guides. Initially, until tertiary educational institutions improve in the rest of Africa, South Africa will serve as a key center for tertiary training. Exposure to South Africa/Southern Africa will provide an enlightening experience to youth from many rural areas of

just what the potential and value is of wildlife and other natural resources. With these skills, community-owned safari and tourism businesses will evolve, as described in Section 9.7.6.5, Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders.

Unless the wildlife populations and natural beauty are exceptional, the chances are that the core business will be safari hunting that will serve as an “embryo of conservation”, allowing wildlife populations to build up, where other ventures such as eco-tourism may become viable. However, as discussed, the protected area must operate as a large corporation with many companies, providing income generating opportunities at the household level sustainably exploiting the myriad of resources traditionally taken from these natural systems: wildlife for trophies, wildlife for meat, fish, lumber, charcoal, thatch grass, honey, other wild foods and medicines, pasture, etc. (see Section, 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa). The management plan of the area will be developed by this educated group “planted” back into the community, which will take Western concepts of intensive management and monitoring and integrate this into traditional management systems and controls as discussed in Chapter 2.

Even with tertiary education, youth will only have the basic skills to begin learning. Running safari companies, marketing, dealing with clients and different cultures, etc. are skills learned in the field. Initially, teaming up these graduates with a “mentor” safari/tourism operator will be critical. As discussed above, ideally, it should be someone semi-retired or retired who can be hired on a salaried basis by the community over a five to 15 year or longer period who will “teach them how to fish” until they feel they have enough experience in putting in roads, in camp building, in judging trophies, in marketing overseas shows and in understanding the kinds of foods and hunting experiences desired by different

nationalities. One of the biggest shortcomings of rural communities, with regards to valorizing wildlife, is poor links to the marketplace must be overcome!

Without a combination of both tertiary and practical skills development, there will be no independence of rural communities from exploitative middlemen and CBNRM will be doomed to failure. Furthermore, as discussed, many of the skills training needed by rural Africans has nothing to do with CBNRM and resource management and marketing, but with taking the majority of the youth out of the rural areas into an urbanized global economy to relieve pressure on the overly stressed rural systems and their resources.

9.8.2.4 Physical capital

A major constraint for most communities and the returning students will be money to jump-start a company, purchasing a vehicle and basic equipment to supply a hunting/tourism camp. Nice camps can be built with local materials, but such items as beds, a refrigerator, freezer and cooking equipment must be purchased. There will also be costs in having someone with access to the Internet to be in regular contact with clients and prospective clients. Plans must exist to help these communities obtain low interest loans to start these businesses. This may not be easy as they usually have little or collateral (e.g., land, home, etc.) that can be used to secure a bank loan. Once again, tenure becomes a major issue. This is one area where donors and/or NGOs might play a role in helping to jump-start these enterprises, though there should be no handouts. Possibly a better option and beginning to happen with rural communities bordering the Kruger National Park (Brits, *pers. comm.*) is one where joint ventures are being undertaken with the private sector with 15 year leases that includes putting in the infrastructure such as lodges and fencing. The private sector provides various

levels of training at all skill levels with the idea that in 15 years the lodge/business is turned over to the community.

Since 2003, the World Bank has created the Grants Facility for Indigenous Peoples” available for nationally registered NGOs within a given country It supports:

- Innovative pilot projects that build on indigenous culture, identity, knowledge, natural resources, intellectual property and human rights, and/or institutions;
- Planning and preparation of development projects implemented by indigenous peoples, communities and organizations;
- Recommendations made by the UN Permanent Forum on Indigenous Issues on social and economic development areas; and
- Development of partnerships and alliances with other stakeholders, such as governments and international organizations, or between indigenous peoples and organizations.

Grants are given for US\$ 10-30,000, with the NGO having to demonstrate that it has 20% of the grant in cash or in kind and has a legally established bank account in its name. Detailed information on this program and applications should be sent to indigenouspeoples@worldbank.org. It should be clearly understood that even the amount of money required to apply for such a grant, while small by Western standards are large by Sub-Saharan African standards.

9.8.3 Devolution on Private Game Ranches, Southern Africa, Short-Term Success, Long-Term Failure?

CBNRM is not about private ownership, but the way in which governments empowered the private sector now needs to be undertaken at a community level.

However, as a precursor to CBNRM that demonstrates the importance of devolution as the basic tenet to successful wildlife management, one of the most successful examples of conservation has been on private game ranches and conservancies in South Africa, Namibia, Botswana and until recently in Zimbabwe, where wildlife is displacing livestock at a rapid pace. The landowner – in this case private individuals, as opposed to communities – has exclusive rights to determine how wildlife will be used, who he selects as partners and ultimately has exclusive rights to benefit from wildlife.

Major differences between CBNRM and commercial game ranches in Southern Africa are (ZAWA, 1999):

- Managed under single ownership, generally needing to support only one family and not 100s or 1,000s of families. In many cases (e.g., South Africa) they serve as weekend places, secondary incomes or even tax write-offs for wealthy professionals or businessmen living in the city);
- Outsiders (e.g., local communities) excluded so that conflicting land uses (e.g., agriculture, livestock, fishing, charcoal making, poaching, etc.) are virtually eliminated unless desired by the individual landowner;
- Game, a fugitive resource, tends to be fenced-in, especially in South Africa, but not so much in Namibia or Zimbabwe, and is thus more easily accounted for by the owner;
- Minimal government interference;
- Long-term tenure assured with vested incentive to reinvest profits back into ranch and into building up trophy quality of wildlife;
- Rancher owns wildlife as opposed to government in most communal areas with trophy fees and daily rates going to landowner who pays income taxes instead of directly to government;

- Game ranches on smaller areas ranging from 500-12,000 ha on average allowing for intensive management of species and habitat as opposed to vast extensive areas of safari hunting blocks in communal areas that can be 1,000s of km²; and
- No limits on how wildlife is marketed (e.g., in many communal areas certain species, such as leopard, lion and elephant, can only be taken on 14 or 21 day hunts depending on country, and more flexible seasons).

Countries with strong economies and commercialized wildlife sectors, such as South Africa and Namibia, show the highest proportion of increasing species populations (Cumming, 2004 *In: Child, B.*, 2004a). In South Africa, there is more wildlife today than at the turn of the century, the majority being on private land. In South Africa in 1999, there were an estimated 17 million ha consisting of 9,000 privately owned game ranches employing 63,000 people, while there were an estimated 7 million ha consisting of 19 national parks and 421 provincial parks/reserves. There was 2.5 times more game on private ranches versus public lands (African Advisory Board, 2000a); while in the rest of Africa wildlife and wildlife habitat are on the decline. By 2004, it is estimated that there were 9,000 privately owned ranches covering 17 million ha of land employing 70,000 people, including professional hunters (PHASA, 2004).

“In Zimbabwe, there were approximately 2.7 million ha of land under commercial wildlife production (nearly 7% of the country), an increase from about 35,000 ha in 1960. Of 4,000 commercial farmers, 1,200 were actively engaged in wildlife production, and several large conservancies (Save Valley, 326,000 ha, Chiredzi River, 80,000 ha and Bubianna, 127,000 ha) were beginning to appear as mechanisms for scaling up wildlife management. The amount of wildlife quadrupled in a 15-year period” (*Child, 2005 In: Lyman & Child, 2005*).

In Namibia, about 18–24% of commercial land is used for wildlife production properties, with over 400 registered commercial hunting properties. Between

1972 and 1992, wildlife on commercial land increased from 700,000 to nearly 1.2 million animals and is continuing to rise. There are 24 conservancies, double the number since 1988, covering close to 4 million ha (Child, 2005 *In: Lyman & Child, 2005*).

This shows us just how far CBNRM has to go.

As impressive as this may seem, the majority of these private farms and conservancies are in the hands of a white minority, wildlife being inaccessible to the majority of Southern Africans. In South Africa, many of these game ranches are weekend getaways for urban-based professionals for both personal and corporate entertainment, only a small percentage of them having to economically support the owner full time. In many cases, they serve as a tax write-off, though South African law is making this more difficult.

The question that continues to arise is the following,

“Is the current distribution of wildlife and associated land, both public and private, sustainable, when it is available to only a small fraction of South Africa’s/Southern Africa’s population”?

Many would argue that unless the economic and land tenure dynamics of Namibia and South Africa change, more “Zimbabwes” could be around the corner (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife). In both countries, game rancher/farmer associations, professional hunter associations and some professional hunting schools are developing black economic empowerment (BEE) schemes to make the wildlife industries more inclusive of the formerly disadvantaged. Proactive action oriented programs are needed now!

An additional threat to South Africa’s wildlife industries is an attempt to over-regulate from central government. The National Environmental Biodiversity Act of 2004 (RSA, 2004) and associated draft norms and standards of the hunting

industry (DEAT, 2006a) was developed by a “panel of experts” that did not involve the game ranchers nor the provincial nature conservation agencies (the line managers), game capture/translocation, sport or traditional hunters. Other than representation by the Professional Hunters Association of South Africa (PHASA), the panel members were mostly urbanites consisting of scientists, bureaucrats, union leaders and others whose lives are not directly tied to living from the resource, the draft hunting norms and standards reflecting this urban bias. The panel’s recommendations leading to the development of norms and standards for hunting could detract from the economic viability of the industry [e.g., with minor exceptions - no trophy hunting on national or provincial protected areas; no Problem Animal Control (PAC) by overseas trophy hunters; breeding for color variations may be out such as golden wildebeest, white and black springbok; making it difficult for ranchers to keep wildlife that is not found within its natural range limiting the diversity of product provided to client hunters; closure of hunting for captive bred lions and general restrictions on captive breeding] (DEAT, 2005a; 2005b; SA Wingshooters, 2005; DEAT, 2006b; Hoogkamer, *pers. comm.*). These policies must be discussed and implemented in collaboration with the game ranching and hunting industry.

The game ranching and hunting industry is concerned that there is a desire to impose biodiversity as a priority on their ranches, where they see ranching as first farming with biodiversity as a secondary spin-off. At worst, there is fear that lurking behind the scenes is the urban-based animal rights movement that wishes to see hunting closed. They argue, why can exotic species of livestock be placed on the land, but not wildlife, as long as the wildlife does not suffer? Certainly, few people in the game ranching industry would condone mixing of gene pools such as western roan with southern roan, the Lord Derby eland with the Cape eland, or the blue wildebeest with the black wildebeest, which produce reproductively viable offspring. This needs strict regulation. Why is unidirectional breeding, or “upgrading” by the livestock industry considered appropriate (Hammack, 2003),

but the same process to develop color variants of wildlife inappropriate? Where does “canned hunting end”. What about “put and take” kudu, rhino and the many other game bought and sold at game auctions even by provincial nature conservation officials. Should this be stopped? Care must be taken that this lucrative industry is not forced out of wildlife and back into cattle ranching that could result in a loss of biodiversity across the country (maintenance of natural habitat with regards to soils, vegetation, insects, small mammals, reptiles, amphibians, etc.).

In essence, this is what we are seeing all over Sub-Saharan Africa, where rural people are opting out of natural systems for man-made systems because of centralization of control, expropriation of benefits, tenure issues and over-regulation.

In addition, as implemented, the firearms act (SAP, 2000) is also discouraging overseas hunters as well as prospective local hunters, who are more important than the overseas hunters (see Chapter 5, Section 5.12.7, Attaining Food Security through More Appropriate Land Use Options, Wildlife as a Land Use Option on Marginal Lands), from supporting this important economic sector in South Africa. Combined, this legislation could shut down hunting and spell the end of game ranching in South Africa if improper regulations are adopted and/or improperly implemented. In addition, requirements such as training and belonging to various hunting organizations in order to obtain a firearms license may economically preclude many black South Africans from joining the hunting fraternity, keeping it an exclusive white hobby that in the long-term could be its downfall.

9.8.4 Devolution and CAMPFIRE, Zimbabwe

Legally, communities do not have appropriate authority. As noted, this has been granted to Rural District Councils (RDCs), which are large heterogeneous administrative units rather than production units. Producer communities come at

a lower level (e.g., ward and village). There is thus legal discrimination at this point in time between private farms (wildlife producer units) that control their own revenue and resources and communal producer units that do not. RDCs and district wildlife committees are regarded as remote and with skepticism by rural communities (Wels, 2000). LWAG/DFID (2002) note that through the 1990s, donors began to question the cost-effectiveness of programs like CAMPFIRE in which revenue was retained at the district rather than the village level.

In 2000, the CAMPFIRE Association, which represents local government (i.e. Rural District Councils [RDCs]), voted for devolution of appropriate authority to the level of the producer community. This is at the ward/village level. Wards make up about six to ten villages. Each village agrees on a geographical area of influence. The trophy fee from any animal killed within the area of influence of a given village would go directly to the “producer village”. Concession fees were to be divided, 20% would go to the RDC and the remainder would be divided among the villages. The safari operator would pay respective fees directly to the respective village or RDC. This would have been a major change in a number of ways: 1) “producer villages” would be recognized and would receive direct benefits, the amount determined by the level of protection provided to wildlife and thus its availability for trophy hunting, 2) thus it would be in the interest of each “producer community” to protect its wildlife and 3) the cash would flow directly to the producer community as opposed to the past difficulty of extracting its share from local government.

Chiredzi RDC was the first local government to implement this new process (Sithole, *pers. comm.*). Linked to this have been attempts to create village run trusts as in Botswana. All of this is theoretical as Rural District Councils (RDCs) have resisted this change (Sparrow, *pers. comm.*; Duffy, 2000) and it is doubtful that much will happen until the post-Mugabe era. Duffy (2000) argues that this

coercive conservation assists in the expansion of state control over rural areas. She believes that as a result of World Bank/IMF driven structural adjustment policies (SAPs) and declining revenue to both central government and Rural District Councils (RDCs), rather than devolve authority to the wards and villages, attempts will be made to re-centralize control over this income.

Murphree (1997) is even blunter about how far devolution might go and raises concerns over the future of CAMPFIRE:

“At the national level the economic performance of the (safari) industry has attracted the attention of the political elite and their private sector allies, who seek to appropriate a higher share of its value through patronage, shrewd negotiation or bureaucratic re-centralization. CAMPFIRE, which from its conceptualization had profound political implications, has through its relative successes now become a high-profile arena of political maneuvering with outcomes which will remain dynamic and dependant of the strength of its constituency”.

The constituency are the rural uneducated poor, who unless they have a champion in the form of national or international leadership will be taken advantage of until they themselves are sufficiently educated to be able to maneuver within the system and stand up for the rights of the greater good.

Murphree (1997) discusses the compartmentalization of natural resources in different ministries, the reason that up until now CAMPFIRE and most CBNRM programs have been mainly about wildlife and fisheries linked to hunting and tourism. Timber and mineral resources are other important sources of revenue over which communities will need to negotiate user rights if CBNRM evolves in Africa.

9.8.5 Devolution, ADMADE and LIRD, Zambia

9.8.5.1 ADMADE

In 2001, then President Frederick Chiluba closed hunting – reopening in 2003. While corruption was given as an excuse, the problem appeared to lie in a struggle over control of the presidency and political power of the country. It is believed that Chiluba closed hunting to get back at very powerful political individuals who were in the opposition party, including:

- Ben Mwila, possibly the richest man in the country and uncle to Chiluba;
- General Tembo; and
- Two senior politicians whose names were not forthcoming.

It is also alleged that closure of hunting was linked to punishing powerful elements within the Indian community who controlled hunting. The Indian community that originally helped put Chiluba in power backed a pressure group within the ruling party against Chiluba running for a third term.

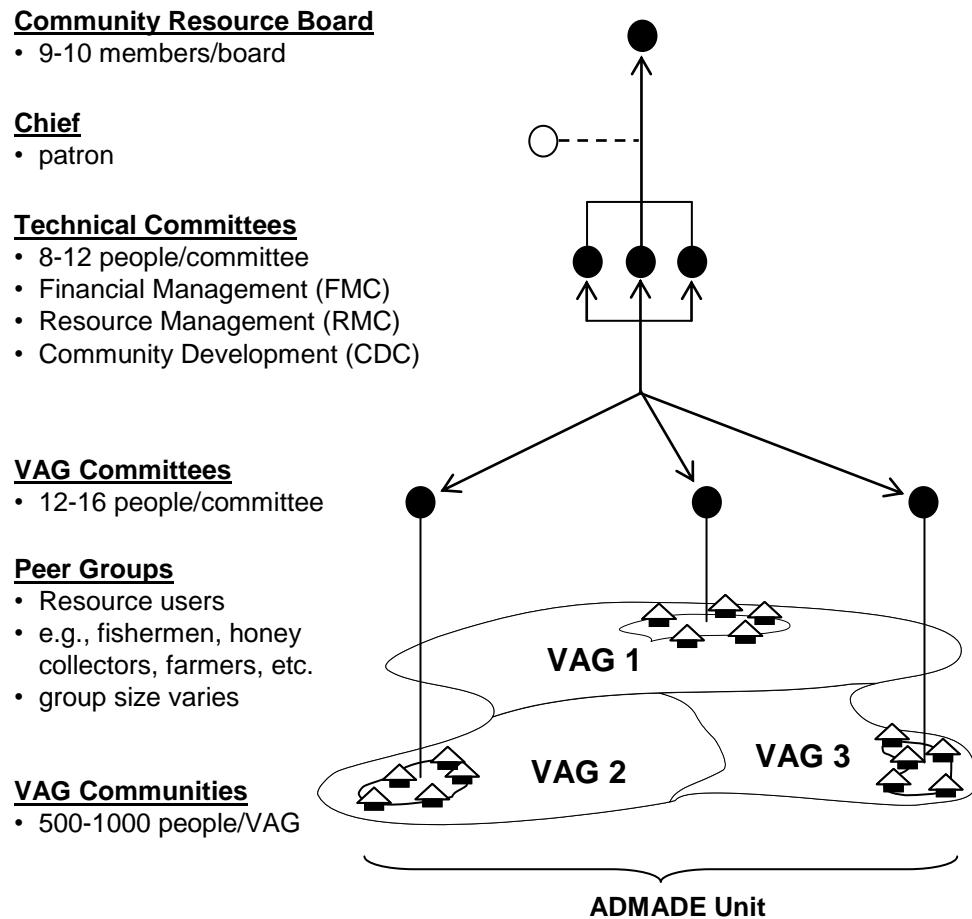

At least four of the 19 safari companies had high-level opposition politicians involved. Based on a confidential EU report, ZAWA's finances for 2001 were expected to be as follows (DeGeorges, 2001b; SCI Africa Office, 2001b):

<u>Source</u>	<u>Billions of Kwacha (K)/US\$</u>	<u>% Of Total Revenue</u>
Government	8.7/2,861,842	39.6
Non-Consumptive Tourism	3.0/986,842	13.6
Hunting	10.3/3,388,157	46.8
GRAND TOTAL	22/7,236,841	100
Kwacha 3,040/US\$ in 2001		
DeGeorges (2001b; DeGeorges In: SCI Africa Office, 2001b)		

With the closure of hunting, the deficit to ZAWA in the report was estimated at K 19 billion (US\$ 6,250,000) (Not sure how they came up with that figure – possibly from a combination of revenue loss plus declining government support). The government had reduced its contribution to ZAWA from K 8.7 billion (US\$ 2,861,842) to K 3 billion (US\$ 986,842) in 2001 (SCI Africa Office, 2001b). According to ZAWA (2002 *In:* de la Harpe, *et al.*, 2004 *In:* Child, 2004a), the proportion of the national budget allocated to wildlife dropped from 0.29% in 1966 to 0.10% in 2002. In 2001, salaries had not been paid for three months, staff being forced to live off of credit. Without support from the communities and safari operators, the cost of being in the field and employing staff to save the wildlife was estimated to rise to K 36.7 billion (US\$ 12,072,368). According to the confidential report, donors were losing confidence in Zambia due to the closure of hunting. This was a very interesting statement being made about donors representing countries with large animal rights movements who would be happy to see hunting closed (DeGeorges, 2001b; SCI Africa Office, 2001b). By comparison, in 2005 out of a gross income to ZAWA of Kwacha 44,124,000,000 (\approx US\$ 10 million) the amount of 13,771,000,000 (\approx US\$ 3.1 million/31%) came from hunting license and concession fees, \approx US\$ 2.3 million/23% from park income, \approx US\$ 2.5 million or 25% in donor grants, \approx US\$ 1 million/10% in government subsidies and \approx US\$ 992,954/9.9% from exchange rates and other income. Although pressure is being placed on ZAWA to give up more revenue from hunting to GMAs they cannot afford to until alternative sources of income are found (e.g., increased revenue from expanding non-consumptive tourism or restructuring of hunting fees) (Hamilton, *et al.*, 2007) (see Section 9.5.2, ADMADE, Zambia).

Transformation is taking place. The Wildlife Management Sub-Authority (WMSA) structures will be replaced with democratically elected Community Resource Boards (CRBs), whereby the chief holds a non-voting honorary position

(Lyons, 2002). Legislation in 1998 makes provision for CRBs (Jones & Murphree, 2004 *In: Child, B.*, 2004a). It appears that CRBs are linked to Village Area Groups (VAGs) (ADMADE Foundation, 1999; Lyons, 2000) as discussed under LIRD (see Section 9.8.5.2, LIRD) (Figure 9.4).

Source: Lyons (2000) with permission, Lyons.

Figure 9.4: ADMADE organizational structure for a single game management area (GMA)

These CRBs have been set up in most areas, but because of ZAWA's long restructuring, none have been legally registered. With no money from safari hunting in 2001 and 2002, the proof of how these CRBs and ZAWA will function has yet to be emerge, with revenue flows yet to come in. In addition, ADMADE is

now much more focused on supporting poverty and food security issues, which is showing positive results particularly in the Luangwa Valley (Lyons, 2002). Who will pick the hunting concessionaires? Will cash flow directly from the safari operator to the CRBs or still flow through the awkward, centralized and unaccountable revolving fund? According to Jones and Murphree (2004 *In: Child, B., 2004a*), the money still appears to flow through the centralized revolving fund, where in neighboring programs such as Botswana and Namibia, income from wildlife goes directly to the communities. The continuation of the revolving fund is implied in the ZAWA (2004) draft CBNRM document. Time will tell, but with the majority of rural communities poorly educated and organized, at this point in time it is not too hard to guess who will dominate among key actors. According to Simwanza (*pers. comm.*), who will undertake a masters thesis on the subject (Simwanza, 2007), CRBs in 2005/2006 are operational.

Haller (2004), speaking on CRBs around the Kafue, though it is likely the case throughout the country, states

“the formal wildlife regulation – before and also after the Zambian Wildlife Act of 1998 - requires a modern gun and one has to buy an expensive license that locals cannot afford (*ibid*). Even if they could afford to buy a license the transactions costs of getting to know where and how to get this document in the urban centers are too high. If local people get caught hunting or only in the possession of game meat, they are fined heavily: We were told of people who were sentenced 5 years of prison for only possessing game meat. Additionally, there are reports that locals were shot by game scouts, who are now monitoring the Lochinvar Park and the neighboring Game Management Area (GMA 11). Nevertheless, monitoring is far from being perfect, game scouts are badly paid, transport facilities are bad and the morale of staff is bad too. There are also complaints of local people claiming that the scouts are poaching themselves. So there is no trust whatsoever in the work of the state that shall control the CPR (Common Property Resource)...locals are ignorant of the existence of the CRBs and the money goes directly to accounts controlled by the chiefs or

staff of the chiefs. So the local population as well as the chiefs themselves view that the government is taking away the resource from them, which in their eyes once belonged to them. They therefore do not see the need to protect the animals. But even if money is invested in schools and clinics this gain cannot compensate from the loss they have and also will not exclude free riders from hunting and using these facilities...One part of the population, especially young men, continue hunting - or poaching as the term is used by officials AND locals - with dogs and self made guns in remote areas in the Kafue Flats, where they know that the scouts will not reach because of dangerous animals (crocodiles and hippos). The meat is then dried and sold locally to the people or to traders (male and female), who then sell it at the tarmac road or they travel to Lusaka in order to sell it there. Most of the people hunting want to get access to the resource before it is taken away by commercial hunters from the cities. Those have the money to buy the licenses and are well equipped with modern guns and pick up cars on which they carry deep freezers. Locals claim that these hunters also do pay the game scouts in order to shoot more animals than is issued on the licenses. There are also illegal hunters from town hunting themselves or hiring local hunters" (see Chapter 7, Section 7.9.9.4, Kafue, Zambia).

Child, McKean, *et al.* (2004 *In: Child, B., 2004a*) claim that financial systems are now sound and accountable and for the first time in at least a decade the allocation of hunting blocks

"has not been associated with intrigue, disputes have mostly been settled in court and contracts are clear and transparent".

It is hoped that this is true and remains the case. Inside sources (Anon 2005, *pers. comm.*)²⁹² explain that the system is still corrupt and based on patronage heavily linked to ZAWA's commercial services division, with the Indian community once again heavily controlling/influencing the allocation of hunting blocks and thus hunting in Zambia. Simwanza (*pers. comm.*) explains that in 2006, an external audit exists creating an aire of transparency with funds arriving in a timely

²⁹² Anonymous. Name withheld to protect the integrity of the informant.

manner at the level of the CRBs not being an issue. The problem now is transparency by the CRBs in what they are doing with the communities' income. When accounted for, most income is still used for common property benefits, and though it is increasing, it is still relatively meager at the household level.

At the same time, because ZAWA is a parastatal and no longer receives government funding, there is concern that ZAWA is in the process of extracting too much money from what should be community tourist income, resulting in a disincentive to communities to conserve their wildlife (Child, McKean, *et al.*, 2004 *In:* Child, B. 2004a). Faddy (*pers. comm.*) was concerned that neither the income from hunting nor eco-tourism would be enough to financially sustain ZAWA as a parastatal since the overall tourism industry of Zambia is just too small. De la Harpe, *et al.* (2004 *In:* Child, 2004a) believe that this illustrates the dangers of imposing financial self-financing too quickly on an agency with so much power.

A recent study by the Hamilton, *et al.* (2007) found that there were neither welfare gains nor losses associated with living in GMAs or participating in CRBs/VAGs for poor households, while non-poor households in GMAs would significantly be worse off if their community had not been declared as a GMA or they did not participate in CRBs/VAGs. This implies an inequitable distribution of benefits (elite capture) to the more politically connected and better off households in GMA village society.

9.8.5.2 LIRD^P

The next-door Luangwa Integrated Resources Development Program (LIRD^P) since the mid-1990s has attempted to devolve more authority down to the village level. In 1996, LIRD^P's review and policy committees (comprising senior civil servants) approved a new CBNRM policy for the project. The turnaround in the

community program and all later progress in the CBNRM program can be traced back to this four-page document (Child & Clayton, 2002). Village Area Groups (VAGs) were created of which there are 43, representing an average of 116-163 adults/VAG.

“VAGs were constituted at a scale that ensured the face-to-face participation necessary for grassroots democracy in largely illiterate communities (roughly 200 households)/VAG. The revenue distribution process became the driving mechanism” (Child & Clayton, 2002).

Each of the 43 VAGs committees consists of ten elected members that meet monthly. Child and Clayton (2002) believe that

“the probability of a community program being successful is linked strongly to scale, because operating at Village rather than Area level allows the harnessing of the power of participatory democracy and downward accountability”.

While it is important that elections are regular, there is regular accounting and reporting to the village, and while the chief plays a role, he is no longer the sole decision-maker. The latter issue is important since in recent times “chiefs” tend to be government employees with more allegiance to the bureaucracy than their people and as described in ADMADE (see Section 9.6.2.2, ADMADE, Zambia) have tended to use their power to expropriate income, quotas and other tools of power in order to retain power through client/patron relationships.

Money from the Lupande GMA was banked in a joint account with community and project signatories. The money was split: 1) 80% to VAGs, 4% to ADCs²⁹³,

²⁹³ Each of the six chiefs in the LIRD program has an area development committee (ADC), with three to ten VAGs/ADC providing a coordination role and oversight in wildlife management. Because of the chief being above auditing, the ADCs were less accountable and less transparent than the VAGs and were therefore also less capable of implementing projects and hence experienced more misappropriation of funds than VAGs (Child & Clayton, 2002)

3) 6% +/- 2% to chiefs and 3) 10% contingency (reserved to employ ADC executive secretaries) (see Section 9.7.6.4, CBNRM will not create a “middleclass” in rural Africa, LIRD, Zambia). Revenue from the two hunting concessions in the GMA is divided equally between six areas, one for each traditional chief. The VAGs within the areas meet to determine how money is to be distributed between VAGs. Each VAG then determines what percentage of its income goes to projects (common property benefits), households (*tyolela*), VAG administration and wildlife management (Child & Clayton, 2002). Continued weaknesses of LIRD include (Child & Clayton, 2002):

- Administration of LIRD is expensive and heavily dependent on outside donor funding for expatriate and national staff, US\$ 2 and US\$ 4/person/year (45,000 people), but cheaper than many, at less than a quarter the cost of Namibia’s program in the Caprivi area. This funding has been significantly reduced in recent times.
- It appears that LIRD staff determines if VAGs fulfill predetermined requirements prior to releasing money – still a top-down process. What will happen when the LIRD project ends? Who will assess and continue demanding audits? Will this come from the VAGs themselves?
- While there have been some attitudinal changes, “poaching” in some villages is still an issue.
- As in ADMADE, there is little transparency in the awarding of hunting concessions, resulting in a major loss of revenue to rural communities (e.g., much of the quota allocated as meat to non-resident hunters for political favors). As a result, Zambia earns less than 10%/unit area compared to Zimbabwe, South Africa, Namibia and Botswana.

The dependency on project donor funding and outsiders controlling the flow of benefits puts into question the long-term sustainability of this program, unless

LIRD^P and similar CBNRM programs can be weaned off donor handouts and create their own transparent processes that members of the community can trust.

“Because this is so frustrating, many projects have by-passed inefficient government systems, setting themselves up as mini-bureaucracies but, usually, these have collapsed once the project has ended” (Mellors, 1988; Dalal-Clayton & Dent, 2001 both *In: Child & Clayton, 2002*).

The success or failure of what LIRD^P leaves behind can only be determined once LIRD^P ends - by an evaluation, maybe two years later!

9.8.6 Devolution and LIFE, Namibia

The concept of a bottom-up CBNRM program was further defined in the review of the Namibia CBNRM Living in a Finite Environment (LIFE) Project (USAID, 2001) with recommendations towards moving in the direction of truly empowering local communities – in this case community-based conservancies to make their own decisions. The following is an alternative structure or vision for the National CBNRM Program that (Figure 9.5):

- Places democratic grassroots representation center-stage as the legitimate lead organization;
- Insists on conservancy committees developing “democratic roots” into their constituencies;
- Maintains the invaluable Namibian Association of CBNRM Support Organizations (NASCO)²⁹⁴ Namibian Government (GRN)/ NGO coalition, but in a supporting rather than central role. (NACSO-coordination, NGOs-delivery); and

²⁹⁴ The Namibia Association of CBNRM Support Organizations is an umbrella association of 12 CBNRM service organizations (11 NGOs and the University of Namibia) providing services to communal area communities seeking to manage and utilize their natural resources in an equitable and sustainable manner. <http://www.nasco.org.na/introduction.htm>.

- Strengthens the ability of communities to work with the Ministry of Environment and Tourism (MET) and other agencies to fulfill the policy of supporting the rights of rural formerly disadvantaged Namibians.

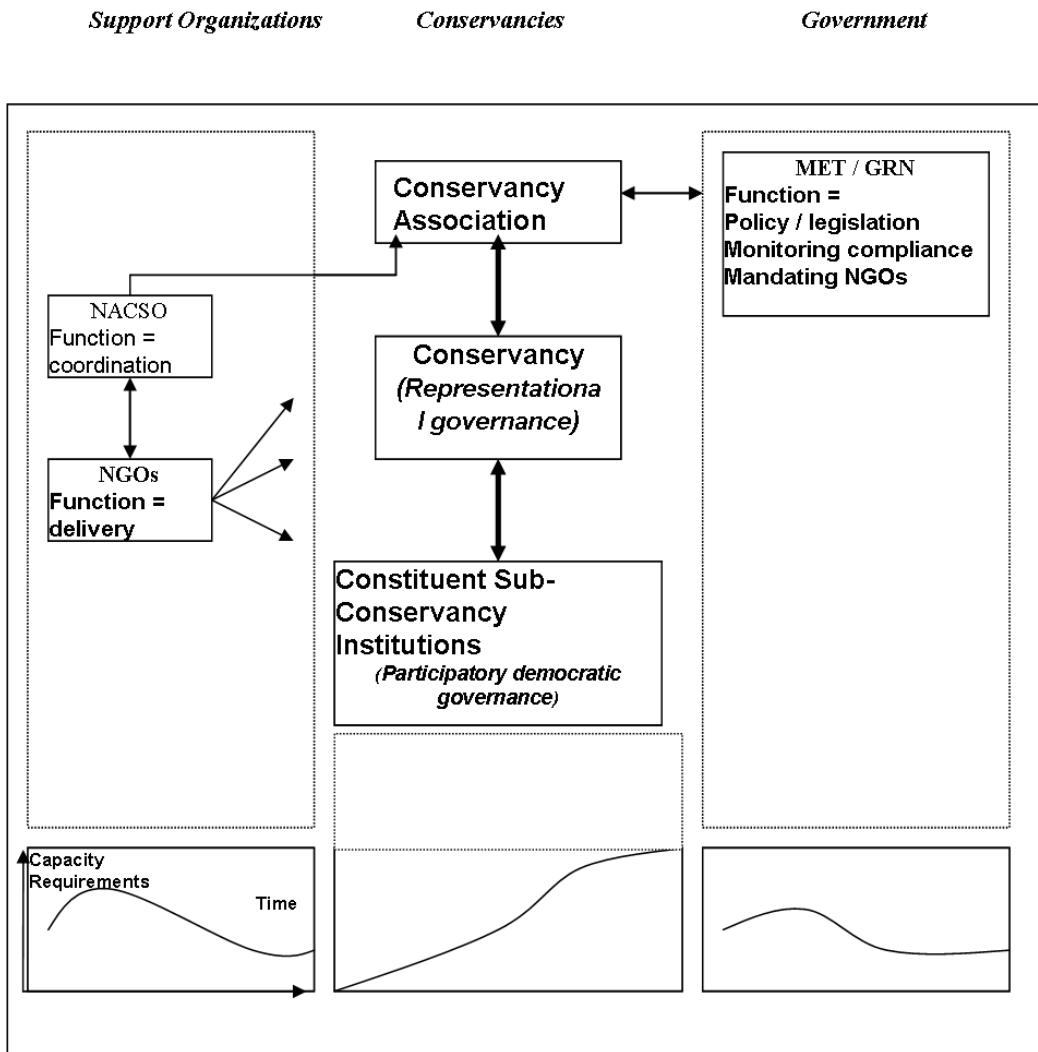

Figure 9.5: Evolution of empowerment and capacity in Namibian conservancies

With time, as conservancy capacity builds up, support and involvement from outside organizations should decrease as shown in the accompanying chart. A major emphasis is placed on creating a transparent and democratic environment within the conservancy system, something that is a weak link in most CBNRM

programs in Africa. In summary (USAID, 2001): 1) it needs to be based on sound, democratic participatory organization, 2) it needs to take advantage of the opportunities for commercial enterprise development to make money and achieve financial sustainability, 3) it needs to ensure sustainability, especially of the wildlife and resource base, 4) it needs to keep the social dimensions and dynamics clearly in view and monitor to insure equitable impacts and 5) the program needs to develop grassroots legitimacy and the democratic ability of its constituents to empower themselves. It is not sure what is meant by democratic in this sense, though it has probably been added as part of the Western donor political rhetoric. As noted in Section 9.7.4.2, Ignoring cultural constraints in institution building, LIFE, Namibia, Nyae Nyae Conservancy, the egalitarian society of the San people does not necessarily mean an easy transformation into democracy and other Western institutions. It would have been better to say that the majority of the people in the conservancy have a say in how their resources are used and managed and in how benefits are distributed. The LIFE-II evaluation also recommended the “opening of doors” to other stakeholders such as the private sector, which currently plays a key role in helping conservancies market their resources. Additionally, institutional strengthening is mentioned as a key need, with little mention of how this should take place.

9.8.7 Ilngwesi Lodge, Mukogodo Pilot Tourist Program, Kenya

The following information was provided by Gilfrid Powys (*pers. comm.*), a rancher in Laikipia, Kenya. Though on a local scale and not countrywide, this case study demonstrates that rural Africans can organize and successfully run exclusive facilities catering to high-paying overseas tourists.

9.8.7.1 Location

The IIngwesi Lodge in the IIngwesi Group Ranch is located on 60,728 ha (150,000 acres) east of the Mukogodo Escarpment at an elevation of 4,000 feet mean sea level (MSL) and is part of a group ranch owned by 450 families. It is on the northern boundary of the Lewa Wildlife Conservancy and the Borana Ranch (Gilfrid Powys, *pers. comm.*). According to Barrow, *et al.* (2000), this group ranch is on 8,600 ha with about 600 members, and provides important wet season habitat for giraffe and elephant coming from the 30,000 ha Lewa conservancy. Watkin (2003) estimates 400 households representing 3,000 people on 16,000 ha with 8,000 ha designated as a conservation area.

9.8.7.2 Illaikipiak Maasai

The people in this area are traditional hunter-gatherers, the Ndotobo-Maasai. *Ndotobo* means blacksmith in the Maasai language of Maa. They are survivors of intra-Maasai conflicts, raids and wars over-grazing range and water points. Their original name was the Illaikipiak Maasai. Their disintegration resulted in the assimilation of the remnants of the Illaikipiak Maasai by the Ilmookodo hunter-gatherer Cushitic group occupying the Mukogodo Forest. Today they are called the Illaikipiak-Ndotobo Maasai (Powys, *pers. comm.*). Culturally, they hunt, gather honey and wild fruits and have livestock. Barrow, *et al.* (2000) call them the IIngwesi.

9.8.7.3 IIngwesi Lodge funded by AWF through Laikipia Wildlife Forum

Money provided by the African Wildlife Foundation (AWF) through the Laikipia Wildlife Forum helped to construct the IIngwesi Lodge. This lodge is owned and operated by the IIngwesi Group Ranch. It has a decision-making board composed

of elders from the group ranch and two members of the Laikipia Wildlife Forum. Tourist safari hunting (if hunting ever re-opens in Kenya) and eco-tourism will generate income from this lodge and its environs. Wildlife from the private ranches of the Laikipia Wildlife Forum will be used to restock this area. Already, snaring has been virtually eliminated as the community begins to derive benefits from this lodge. According to Barrow, *et al.* (2000), the group ranch formed the *IIngwesi* Co. Ltd. and was given a grant by the Liz Claiborne Art Ortenberg Foundation, with the African Wildlife Foundation (AWF) and Kenya Wildlife Service (KWS), which was completed in December 1996.

It is important to note that though NGOs and government helped fund the start-up of this program, it appears to be entirely run through the Laikipia Wildlife Forum, which is composed of private entrepreneurs, Laikipia ranchers, who used entrepreneurial moneymaking skills to help this program become successful.

9.8.7.4 Benefits to local community

The lodge is rented at US\$ 250/night for the entire lodge. This is generating about US\$ 50,000/year for the community (in 1997), work benefits and most importantly restoring pride to these rural people in that they are beginning to feel secure over their futures (Powys, *pers. comm.*). Barrow, *et al.* (2000) confirm this annual income. If there are 450 families, this amounts to a gross of US\$ 111/household. According to Watkin (2003), they are earning about US\$ 38,000 (Ksh 3 million)/year of which 33% goes to employment, 33% to ecotourism operating expenses and 33% to community benefits including school improvements, scholarships, and provision of health facilities. Averbeck (2001) estimates profits of US\$ 21,000/year in which a board of trustees and members have so far used proceeds, as in most CBNRM projects, for common property benefits (e.g., dip tanks for cattle, renovation and building of schools, purchase of

vehicles, improvement of the communication system, roads, scholarships for students, funding of water projects). Everyone from the cook, guides, managers, etc. comes from the local community and this is considered one of the top rated lodges in Kenya. They also explain that it employs 26 people and that marketing and bookings take place in Nairobi. Other important factors often missing in CBNRM projects are:

- All expenditure is authorized by a general meeting of the group ranch members where a quorum needs to be present in order to make any decisions;
- Accounts are audited – creating an atmosphere of transparency and accountability missing in most CBNRM programs; and
- The sophisticated white entrepreneurial ranchers acted as “mentors” to the group ranch in everything from design of the lodge to training personnel to marketing

“The community is using money generated from the project for construction, school bursaries and has bought a vehicle to assist with security and transport of sick people to the nearest clinic. Future revenue will be distributed to individuals and some left over for social facilities.

Several lessons have been learnt. Grants can be used to 'kick start' important conservation projects that can have positive impacts on attitudes and the socio-economic well being of local communities. The interest, commitment and partnership with neighbors who have experience and expertise can also be indispensable. The role of the Lewa Conservancy was critical in this project. Finally, proper institutional set-ups at the local level, systems for marketing the tourism product, training of local people and proper financial procedures were all important ingredients in the success of this project. Attitudes in this community have changed and wildlife has once again become the 'second cattle' ” (Barrow, *et al.*, 2000).

Nyika (*pers. comm.*) is concerned that a major problem is looming. The Lewa Conservancy undertakes all marketing and booking for the lodge. The community is not being trained in marketing and management and thus has no idea of cost/benefits nor how profits are split since accounting is not transparent. These issues need to be addressed with exposure of key community members to the overseas market, as well as training in management and marketing. The Lewa Conservancy, an honorable operation, must slowly divest itself as a middleman.

9.8.8. Rwenzori Mountaineering Services (RMS), Mountain of the Moons, Uganda

This is one of the more successful community businesses in Africa. It is described in some detail in Chapter 11, Section 11.11.3, Rwenzori Mountains National Park - a success story of rural people managing a natural area, and then foreign aid and NGOs arrived.

9.8.9 Gestion des Terroirs, West Africa

When the principal author left West Africa in 1988, the approach to natural resource management by *les agents des eaux et forets*, the game guards of Francophone Africa, was one of repression against the rural communities and was failing. Today, their approach to conservation appears to be further ahead than in Southern Africa, the birthplace of CBNRM. Devolution is not 100%, but close. It still remains to be seen how much of this is donor driven and how much comes from the government truly believing in this process. If it can be made to work, local communities will be empowered to basically own, manage and obtain the majority of the benefits from the sustainable management of their natural resources. A major shortcoming of achieving this success is the lack of tertiary training of community members in various technical areas. Unfortunately, to

date, the World Bank money managed by the government for this process has not deemed such training a priority, preferring to train more government bureaucratic elites far, removed from this program on-the-ground.

9.8.9.1 Management of the Comoé-Leraba Game Reserve, southern Burkina Faso

“Biodiversity loss has reached critical proportions in West Africa. Burkina Faso, an impoverished Sahelian country, is trying to reverse the trend through sustainable management of woodland forests and wildlife. Although somewhat successful, these efforts are curtailed by inadequate financing, capacity, and incentive, as well as increasing pressure from a growing population. Consequently, the country is having difficulties in maintaining its critical ecosystems” (World Bank, 2000).

As over much of Francophone Africa, a system of classified forests (*forêts classés*) was established, these forests being officially off limits to local communities. Traditional controls over accessing Common Property Resources were turned into open access public resources whose management was controlled by the state but whose authority was rejected by the rural populace, while rural small-scale societal management systems were degraded or eliminated. Access to the resources became a free-for-all as these resources were mined for short-term gains by anyone from within and outside the community. This “tragedy of the commons” in some cases took place through patronage systems, where the government encouraged the mining of natural resources that had been managed by communities for centuries (see Chapter 5, Section 5.6.1.1, Impacts of colonialism on agriculture and pastoralism in the Sahel, Groundnuts, Mourides and Land Degradation in Senegal, and Section 5.9.4.7, Deforestation in savanna environments, Deforestation in Senegal Linked to Charcoal Making, Over-Population and Declining Fallow Periods).

Today, protected areas are administratively consolidated by sets of two or three in a Wildlife Conservation Unit (WCU). Burkina Faso contains 13 WCUs. Four WCUs are targeted by Global Environment Facility (GEF) funds: Sahel (several new protected areas in the northern part of the Sahel: Nassoumbou, Séno Mango, Beli, Oursi, Darkoye), Comoé (the Comoé-Léraba Reserve and Boulon-Koflandé Gazetted Forest), Bobo Dioulasso (Mares aux Hippo Biosphere Reserve) and Nazinga (the Kaboré Tambi National Park). The National Natural Ecosystem Management Program (PRONAGEN) will help secure natural habitat and wildlife in about 400,000 ha of the Sudanian savannah, 200,000 ha in the Sahel and several hundred ha of wetlands in the Sahel. Significant restoration is expected in the 100,000 ha (World Bank, 2000) to 125,000 ha (AGEREF, 2006) Comoé-Léraba Reserve.

With support from the World Bank through GEF as a funding mechanism, communities establish inter-village protected area management associations (AGEREFs) to become entrusted as concessionaires. AGEREFs' members are representatives of the *comités villageois de gestion du terroir* (CVGTs)/village management committees of all villages located in the periphery of a protected area. Some investments in protected areas and utilization of wildlife and tourism are delegated by the concessionaires to private professionals (World Bank, 2000).

In Burkina Faso, a program has been undertaken in which the local Dozo hunters guide overseas hunters and undertake anti-poaching and wildlife monitoring in the Comoé-Leraba Game Reserve (see Chapter 2, Figure 2.1: Dozo “professional hunters” Burkina Faso).

The World Bank has signed a five-year agreement with the government to devolve authority to villages around the Comé-Leraba Game Reserve to sustainably manage their wildlife and other resources (Pavy, *pers. comm.*).

Chasse Libre

The economic foundation for the program in the Comoé-Leraba Game Reserve is *chasse libre*. *Chasse libre* or self-guided hunting is a form of hunting in which there is no “great white hunter”. The sport hunter hunts with a traditional “great black hunter”, who until now has been seen by governments and Western NGOs as a poacher. *Chasse libre* mainly takes place in Francophone Africa, especially Cameroon, and is better known to Europeans who have closer ties to Africa and who are often multilingual. Hunting tends to be either by classical foot safari with porters or out of primitive camps sites. It is a market niche for the younger, fitter and less affluent with a sense of adventure, who do not expect “champagne” breakfasts and who are prepared to sit around the campfire and learn about the unique cultures and beliefs of the traditional hunters who serve as their guides, trackers, skinners, porters and cooks.

Fees are lower for the daily rate since the overseas hunters rent their own vehicles, buy their own food, bring their own camping gear and overcome what bureaucratic red tape there is, such as temporary import permits for arms and the purchase of a hunting license, trophy preparation, export documentation and shipping. If a “great white hunter” was employed, he would keep the daily rate anyway (see Section 9.7.6.5, Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders). Therefore, whatever the community charges for the daily rate is a bonus to the community. Just as important is the fact that the community has the pride and dignity of running its own program and being its own boss. With time, as the community’s ability to provide more sophisticated accommodations and services improves, the potential exists to increase income from raising the daily rate.

Comoé-Léraba Reserve

This reserve is found in Banfora and is about a five-hour drive southwest of Ouagadougou. Then another one and a half hours is required to reach the village of Folonzo and another 15-20 minutes to enter the Diefoula Reserve. The Diefoula (Comoé-Leraba) Game Reserve is 125,000 ha. Plans exist to create a wildlife corridor between the Boulon-Koflandé Forest and the Comoé-Leraba Game Reserve, which are linked to the two rivers that join on the southern border of the reserve and which also form the boundary with the Ivory Coast. Contiguous with this reserve, just across the river in the Ivory Coast, is the 130,000 ha Warigué Reserve. Just southwest of Warigué lies the Comoé National Park. Plans exist to create a transfrontier game reserve between the two countries, co-managed by rural communities. However, the civil war in the Ivory Coast is detracting from this goal (DeGeorges, 2003a).

Seventeen villages have created their village management committees - *comités villageois de gestion des terroirs* (CVGTs) and federated them in an inter-village association for the management of natural resources and wildlife/*association intervillageoise de gestion des ressources naturelles et de la faune* (AGEREF). They have allocated 125,000 ha to biodiversity conservation and drafted a management plan. The government has legally recognized the AGEREF (as an association) and is in the process of granting it concession over the gazetted forest.

All income stays with the community, including trophy fees, the daily rate and all employment. Paying trophy fees directly to the AGEREF (e.g., the community) is not possible at this time since the law still says that the trophy fees are taxes to be collected by the government. However, since GEF has been financing a project in these protected areas, they have worked into the grant agreement (which has value

in international law) that the government must pay back the trophy fee to the AGEREF as part of its counterpart financing of the project. This will go on for the next five years while the legal framework is being reformed that should allow direct collection of key economic benefits by the community (Pavy, *pers. comm.*).

All villages have set up their village investment funds (VIFs) and the AGEREF co-manages a conservation fund with the project coordination unit. The “Pilot Community-based Natural Resources and Wildlife Management Project” (GEPRENAF - *Projet de Gestion Participative des Ressources Naturelles et de la Faune* - GEF Project Name) financed or leveraged financing for social infrastructure including wells, rural roads, as well as activities ranging from training, agriculture/livestock conflict management, agricultural research and intensification, soil conservation to micro-credit and literacy. Estimates of wildlife populations are the following (Table 9.19):

Table 9.19: Estimation of the big mammal populations, Comoé-Léraba Reserve between 1997 and 1999

Specie	1997 (730 km ²)	1998 (730 km ²)	1999 (1.000 km ²)
1. Hartebeest	2,435	2,208	2,472
2. Roan antelope	810	979	1,438
3. Bushbuck	155	280	295
4. Oribi	103	197	276
5. Common duiker	103	308	382
6. Red flanked duiker	52	130	170
7. Patas monkey	296	5,145	957
8. Vervet monkey	257	968	975
9. Baboon	237	1177	1,711
10. Warthog	271	371	397
11. Kob	100	1,312	1124
12. Waterbuck	50	60	70
13. Buffalo	100	110	120
14. Hippopotamus	15	20	?
15. Elephant	5	5	?
Total	4,989	13,270	10,387

Source: Echappé (2003) with permission, Echappé.

Data analysis was based on the line transect method at the beginning of the rainy season, within three days using 3-20 km transects with no repetition (Echappé, 2003), so no statistical reliability can be applied to the figures. Nevertheless, if these data are anywhere close to being accurate, this game reserve, which until the intervention of GEF had little or no formal management, has some of the highest concentrations of western roan and hartebeest in West Africa. Might it not be possible that local people were/are much better at managing their natural resources than the state, international NGOs and donors wish to give them credit for?!

The international network of self-guided hunters is going well. The first two overseas hunters from Norway were successfully guided by Dozo (traditional hunters) in 2003. They guided six overseas hunters in 2004 and were fully booked for 2005. Hunting can take place for western savanna buffalo, western roan, western hartebeest, sing-sing waterbuck, harnessed bushbuck, warthog, red-flanked and common duiker. It is estimated that the community could initially earn about US\$ 20,000 (15-18,000) per year from six to seven overseas hunters and more as the game population improves and quotas increase (Section 9.7.6.5, Until safari and tourism companies are community-owned and operated, majority of net profits will go to other stakeholders). There are 20,000 people around this reserve (World Bank, 2000). This amounts to at most US\$ 1/person/year and/or maybe US\$ 7-10/household/year.²⁹⁵ However, there are 17 villages and like most CBNRM programs, this could provide US\$ 1,765/village/year for common property benefits. It is evident that this game reserve, with current wildlife and human populations, falls into the same category of most CBNRM programs both economically and with regards to resource/population ratios that are very low. Where it differs is in the empowerment of communities to run, operate and protect the reserve.

²⁹⁵ Based on personal communications with Morgan Echappé (*pers. comm.*), Technikon Student on this project, there are about 10 persons/household

Major hurdles that this program must address include:

1. Using Dozo hunters to undertake anti-poaching. Poaching is a major problem as depicted below since the reserve has been an “Open Access Resource” for many years;
2. Immigration of farmers from northern Burkina as the land becomes over-used, some places in the north having 90-120 people/km², placing pressure to open the game reserve for agriculture;
3. The community has hired a sociologist who comes from the area to advise them, which is a real bonus. Now, however, funding must be found for some youth from the area to study nature conservation/wildlife management so that the community has in-house capabilities;
4. Traditional hunters must be trained to collect wildlife monitoring data while they are undertaking anti-poaching. Hakizumwami (2000) describes how traditional hunters around Conkouati (Congo Brazzaville) have been used to help estimate the status of wildlife population dynamics – “*increasing, stable, decreasing, disappeared*” - and the approximate distribution map of 47 animal species in the area. Likewise, the anthropologist Stuart Marks (1994) has used Bissa hunters in the Luangwa Valley of Zambia to estimate the status of wildlife populations and was continuing to do so in 2005;
5. *Chasse libre* hunters should also be asked to make observations and GPS them where possible as part of the wildlife monitoring program. This should improve trophy quality and hunter success;
6. Traditional hunting quotas must be established since given the number of villages and the amount of money being made will not stop local hunters, whose identity is hunting, from hunting. Better that traditional hunting be recognized, legalized and authorized so that off-takes can be monitored than continue as an illegal, clandestine activity where the off-take is

unknown, thus making wildlife management impossible. According to Pavy (*pers. comm.*), once wildlife populations reach 70% of carrying capacity plans are for the excess to be harvested as both trophies by overseas hunters and meat by local hunters;

7. The sustainable extraction of other resources such as fish, timber, honey and other wild foods and medicine must be considered as a means of valorizing this reserve and providing livelihoods as a means of justifying to the community its maintenance as a natural system that also directly benefits households, since tourist hunting (sport hunting) on its own is insignificant as currently practiced. According to Pavy (*pers. comm.*), in 2004 this is beginning to happen. The river is being broken into sections and apportioned to various communities to manage and exploit, people are being allowed in for firewood, and there is talk of honey collection. In the 2004-2005 season, while the community netted about \$US 25,000 from *chasse libre*, they netted about US\$ 5,000 from 10 tons of fish (Karama, 2006);
8. It is recommended that hunting guilds be re-empowered to train hunters and to control all hunting activities in the area, since many hunters today are bypassing these guilds, which traditionally controlled who could become a hunter, taught the hunter ethics and determined when, where and what could be hunted. In essence, the hunting guild becomes a modern day sporthunting club and anyone wishing to hunt must be trained by the club, pass their initiation requirements and abide by their ethics – a blend of the old and the new as recommended (see Section 9.7.4.1, Traditional management institutions ignored in favor of Western institutions).

This is already happening in nearby Guinea-Conakry (Oularé, *pers. comm.*). Fairhead and Leach (2003) describe this program in neighboring Guinea-Conakry using the Dozo hunting guilds or *confréries de chasseurs*

(see Chapter 2, Section 2.1.6, Hunting Guilds as a Means of Controlling Access to Wildlife) to manage protected areas and control hunting. This program has support from the government, international and local NGOs and donors. Traditional management systems are being modernized and nationalized. In Guinea-Conakry, there is a National Hunters Association of traditional hunters. At the level of the prefecture, registering hunting societies must sign a nature charter aligning them with national forestry and environment codes to protect endangered species, fight bush fires and reinforce all environmental education and natural resource management programs in the prefecture. In the buffer zone of the *Parc National du Haut Niger*, the chief hunter of each village has been appointed head of a village *wa ton* (bush law) committee and empowered to allocate a limited number of hunting and fishing permits and to regulate who hunts where, when and what, and who sets fires, when, where and how – similar to the past. Fairhead and Leach's (2003) concerns are that this national organization, with Guinea-Conakry's president as a figurehead, has become a de facto army for the government in power. Given that next door the hunter/warrior group Kamajor is operating (see Chapter 13, Section 13.10.2.1, Sierra Leone, war and diamonds) and that many of the rebels in the Ivory Coast civil war are Dozo (Chapter 5, Section, 5.7.4.4, Land reform and civil war in the Ivory Coast), there is concern that this hunters association could develop into an armed political force. Let us hope that this is an over-reaction, since so far, even with rebel movements of Dozo across the border in the Ivory Coast, hunting guilds in Burkina Faso show no indication of such activities. Zeba (1998), in addition to identifying hunting guilds as surviving colonialism and modernization in Burkina Faso, also mentions their existence in Guinea-Conakry, Mali, Senegal and the Gambia, and suggests that these bodies linked to

traditional perceptions of nature can be used as a positive force in conservation; and

9. Benefits from monetary to hunting/resource access rights must be based on the various villages (community factions) abiding by agreed-on rules.

A professional in anti-poaching²⁹⁶ has been hired by the program to provide training to the Dozo. Among other things, the Dozo desire a salary since they leave their families and fields. A meeting between the community and government in November 2003 resulted in an agreement that the community anti-poaching teams can arrest people who are in the reserve illegally and that the teams can have uniforms, though in a different color from those of the military. Also, according to the agreement, these teams will be involved in wildlife monitoring and the valorization of resources from the reserve (AGEREF, 2003).

Pavy (*pers. comm.*) has explained that there is pressure from government for the community to joint venture with a safari operator, who by Burkina Faso law would be black, likely from outside the area and who would likely sublease to a Frenchman. The community is already booked completely for 2005 with *chasse libre* hunters. The safari operator would keep the daily rate so that the community might actually make less money than before, although as noted throughout this document, the pride and dignity of standing on their own and feeling like this is their reserve, their business and their wildlife is every bit as important if not more so than just monetary rewards. Forcing an outside safari operator on the local community would in the mind of the authors be a step backwards in devolution. As of 2007, the community has avoided pressure to move in this direction, maintaining their autonomy. Concern has been raised by Fairhead and Leach (2003) that what appears to be decentralization actually results in more centralization by the state, with additional intrusion by international/local NGOs

²⁹⁶ Raynald Gilon, ex-Belge Special Forces, Katanga, Congo Belge, gilonraynald@yahoo.fr

and Western donors, resulting in more bureaucracy as an impediment to local community autonomy. Time will tell if the government and NGO/donor community are actually willing to devolve full autonomy to this local community and/or will attempt to use *gestion des terroirs* as a means of controlling them through committees and regulations not too different to French colonial indirect rule.

9.8.9.2 Communal natural forest management, Guesselbodi, Niger

Globally, it is estimated that the dry tropical woodland climatic zone occupies 1,250 million ha (1.25 billion ha) of which about 20% are covered with woodland. The bulk of these woodlands, about 64%, are found in Africa. Apart from the Congo Basin and a few other areas, they are the natural vegetational cover over most of the continent south of the Sahara (World Bank, 2003a). They would ecologically be classified as wooded savanna.

The Guesselbodi Project, which was carried out with funding from USAID, was the first major natural woodland management project in the Sahel based on large-scale community involvement. Forests were broken into 15 blocks and each year a given block was harvested, coming back 15 years later to the original block. Livestock was to be kept off a given block for at least one year after it was harvested so as to give the trees a chance to recover mostly through coppicing. Researchers have since found that a six-year rotational period is adequate (World Bank, 2003a).

It should be made clear that community managed forests are not new. In Germany, for centuries, community forests have been commonly managed for wood and game. In the state of Idaho, USA, community-owned forests are

sustainably harvested with income used for the operation of primary and secondary schools.

The Guesselbodi National Forest is located some 25 km southeast of Niamey, the capital of Niger. It is an area of natural woodland covering about 5,000 ha. Ten years after the debut of this project, this forest was perceived as being sustainably managed.

“The Guesselbodi project was especially successful in building an institutional relationship between the Niger Forest Service and the forest stakeholders. The villagers' use of the Guesselbodi natural resources became regulated through a contract between their own cooperatives and the Forest Service. Coming to this agreement involved overcoming resistance from government officials to give up a centralized system in favor of a system where power was shared with the public” (WRI, 1994).

According to a World Bank (2003b) evaluation,

“the Guesselbodi project deserves its pioneering reputation. It showed that, at a technical level, natural woodland management for a sustained firewood yield is possible. It also highlighted, for a wide international audience, the fact that the natural woodlands are far more than a source of fuelwood”.

However, a review carried out in 1993 rather depressingly observed (World Bank, 2003a):

“At Guesselbodi, USAID support has ended, and the activities carried out with project support are now largely discontinued - the systems and institutions created are not functioning as intended. There is poor management of funds, little accountability, and perhaps most importantly, grazing is not effectively controlled following the initial cut. The cooperative no longer has the means to pay guards, nor to pay for soil and water conservation activities, largely because disciplined management of funds was not applied and (as the team was told on several occasions) the cooperative members did not have sufficient managerial or technical skills. (This was indeed a surprising observation in view of the reputation

of the excellent training given at Guesselbodi during project implementation).

Lessons to be learned are that local communities, though they were willing to carry out the forest rehabilitation and protection tasks set for them by the forest service on a paid basis, would not be prepared to continue them voluntarily once the project ended. The Guesselbodi approach was thus not sustainable without continued substantial support from outside donors. If a self-sustaining natural woodland management system were to be devised, it would have to be much cheaper and simple enough for rural people to manage on their own. It would also have to offer such self-evident benefits to local communities that they would be prepared to implement it voluntarily and without external subsidies. The project therefore proposed the establishment of rural fuelwood markets run by a ‘local entity’ such as a village, cooperative of villages, or canton...At the end of 1995, a total of 85 rural markets were in operation most serving Niamey. The total amount of fuelwood sold to Niamey was about 75,000 stéres, about 16% of its total requirement. The total revenue to the markets, less-taxes, was just over 100 million CFA (about US\$ 170,000). About 80% of the total revenues went directly to village woodcutters; about 12% went to village funds; and the remainder went to the market managements. Total taxes were 22 million CFA of which half went to the national treasury with the remainder being allocated between the local forest service and the village community for investment in woodland management and general social welfare initiatives” (World Bank, 2003a).

9.8.9.3 Community-based natural forest management, *Gestion des Terroirs*, Burkina Faso

This program appears to be based on an older Guesselbodi National Forest natural forest management project begun in the 1980s, with lessons learned from the past. The following describes the empowerment of local communities to manage their classified “natural forests” in the “dry tropical woodlands” of Burkina Faso, as opposed to agro-forestry which for the most part was a failure in the 1980s and 1990s and had been imposed on rural communities by western NGOs and donors.

Fruit and nut trees were mainly well received by local communities as part of agro-forestry schemes, but certainly not firewood. Unless the farmer is far removed from the bush, it has been rare that he will wish to grow firewood or livestock forage on his farm, negating the value of agro-forestry in displacing the need for natural forest management.

“The failure of Agroforestry can be summed up as follows: Experts decided the Sahel needed more trees. The World Bank and other organizations (e.g., USAID) spent up to US\$ 6,000 an acre (US\$ 14,820/ha) (using expensive Western NGOs) to grow village woodlots of exotic species that sucked down water levels (e.g., Eucalyptus plantations which no farmer would plant near due to lowering the water table) if they grew at all. Mostly goats ate the seedlings. The idea caused much mirth (laughter) at night when the outsiders (NGOs) jeeps were gone. White men and sleek government officials were telling villagers to pour good water into the ground, on scarce land, for some vague benefit 10 years in the future. Foreigners who stayed to listen learned the equivalent in Bambara, Tamachek, Fulani and Hausa of ‘Gimme a break.’ Foreign experts told Africans not to cut trees” (Rosenblum & William, 1990).

Similarly, Sithole (2004 In: Fabricius, et al., 2004) states that attempts to co-opt community-based resource management committees (RMCs) around the Mafungautsi State Forest Reserve, Gokwe district, Mashonaland, Zimbabwe to plant exotic gum *Eucalyptus spp.* trees were rejected,

“Does it make sense to local people to plant trees when they see the forests as having abundant tree resources”.

Unfortunately, in this case, the valuable timber from the natural forest was given to outsiders (private companies and urban entrepreneurs), while local communities were given limited access to non-timber/minor forest products (Sithole, 2004 In: Fabricius, et al., 2004).

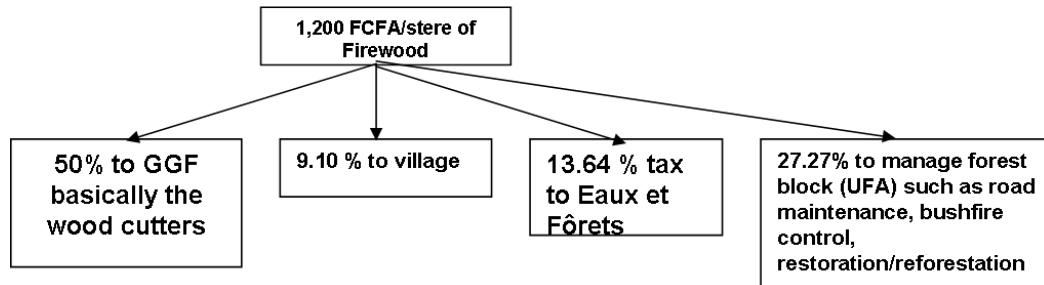

From the principal author's experience covering the Gambia River Basin in West Africa and in his extensive travels and evaluations for USAID in East and Southern Africa, including Madagascar, most tree nurseries lasted only as long as the NGO or researchers were on the spot. People living next to natural forests such as the Bwindi/Impenetrable Forest in Uganda could just not understand why CARE (Food Relief and Development NGO) wanted them to have tree nurseries and plant trees on their agricultural lands [see Chapter 11, Section 11.11.4, NGOs and Eco-Colonialism in Bwindi National Park (BINP), Uganda].

Even when there is a desire to grow firewood, this does not replace the diverse array of resources from natural forests needed by rural people for both subsistence and economic purposes and thus the need for natural forest management, maybe even taking precedent over agro-forestry as a development priority. In Burkina Faso, there is a very complex bureaucracy laid out in the exploitation of these forests. Most important are:

- Forestry management groups/*Les groupements de gestion forestière (GGF)* = forestry management groups, of which one GGF exists for each village – the men that cut and haul out the trees;
- The GGFs exploit forest concessions, *unités forestières d'aménagement (UFA)*;
- The UFA is broken into 15 parcels (*parcelles*) and one parcel is harvested each year through a 15- year rotational cycle; and
- The village-based GGFs are organized under an umbrella body, *L'Union des Groupement de Gestion Forestière (UGGF)* = Union of Forestry Management Groups.

These local level organizations received technical backstopping from the government *Contrôle Technique de L'Etat (CTE)* = the State Technical Control, which consists of the *Direction Régionale de L'Environnement des Eaux et Fôrets* = the Regional Direction of the Environment, Water and Forests, which has the role of monitoring timber harvesting activities, reforestation, forest protection, controlling the timber trade and the management of the forest blocks (UFAs). Fairhead and Leach (2003) describe a similar bureaucratic system in nearby Guinea-Conakry and countries linked to the EU funded Niger River Protection Program and village “forestry groups (*groupements forestiers*)”. Concern is raised that this process becomes a means of relatively autonomous community-created and managed forests becoming absorbed by a predatory state and classified (classified forests),²⁹⁷ placing bureaucratic constraints on the community. What appears as decentralization and co-management or devolution with all of its rules and regulations becomes another move towards centralization.

There is a charge by stere²⁹⁸ for harvested wood. For example, firewood is sold at 1,200 CFA/stere (650 CFA/Euro and about 500 CFA/US\$). This is divided as follows (Ouedraogo, 2000) (Figure 9.6):

Source: Ouedraogo (2000), with permission UN & UNDP.

Figure 9.6 Distribution of income from sustainable forest management, Burkina Faso

²⁹⁷ Village “forest groups” are seen as being a way of the state beginning to control traditional autonomously managed village/community forests, adding to their *fôrets classés* dating back to colonial times.

²⁹⁸ stere = 1 cubic meter = 1.31 cubic yards

The Zone of Silly-Zawara-Pouni – Case Study

This basic approach is being used all over Burkina Faso. The forest of the Zone of Silly-Zawara-Pouni has 35,000 ha of forests managed by a UGGF made up of 50 villages/GGFs, with 50 km of forest roads (Ouedraogo, 2000). Organizationally, the area was traditionally divided into three sectors (Ouedraogo, 2000):

- The villages;
- The soils or lands between the villages (*terroir*); and
- Networks of inter-linked villages (*reseau villageois*)

The village is divided into areas based on lineages, a custom that is slowly disappearing. The *terroir* is an assemblage of all land around the village, based on a pact by the village founder and the genies of the place. Its use is strictly controlled by a number of key members of the village complex in charge of managing the natural resources, including access to cultivatable land and the bush for the purposes of hunting, fishing, gathering and logging. The *chefferie* (chieftancy) is the basis of the village social organization and consists of (Ouedraogo, 2000):

- **The village chief**, who is the traditional administrator and who at times may also play a key role in religious and spiritual activities;
- **The *chef de terre* or the chief of the land**, who is the religious authority and who is in charge of land and its distribution, celebration of worship including sacrifices to assure good harvests and a healthy village;
- **The *chef de brousse* – chief of the bush** – oversees the access to and management of hunting, fishing, gathering, grazing, etc.; and
- ***Chef des marigots*** – oversees the access to and management of water.

The 35,000 ha have been broken into 11 forest blocks, *unités forestières d'aménagement* (UFA). Each block is between 1,883 and 3,875 hectares (Ouedraogo, 2000). In turn, each forest block has been broken into 15 parcels varying between 102 and 197 hectares depending on their production potential. A management plan for cutting is established. Most firewood for auto-consumption comes from opening agricultural fields. There are basically two forms of wood/timber harvests in the forests (Ouedraogo, 2000):

- Harvest of dead wood; and
- Harvest of live “green” wood.

The harvest of “green” wood is based on selective harvests with authorization given exclusively to villages by the forestry service. For “green” living timber, this has been set from January to March each year during the dry season. The harvest of “dead” wood can occur year-round (Ouedraogo, 2000). In a given year, one parcel is harvested, after which that parcel is left fallow for 15 years before returning to harvest the timber resources. In the interim, various other uses can take place within the parcel. Only 50% by volume of a given parcel is exploited, leaving behind vegetation to protect the soil and to naturally reforest an area. Timber to be harvested is marked (Ouedraogo, 2000).

The harvesting technique is based on the concept that most species will coppice. The tree is cut so that the stump is 10 – 15 cm from the ground and the top of the stump forms an inverted “V” to assure that water does not accumulate and rot the stump. Thus, the natural regeneration is preferred to tree nurseries, which have a very checkered history of poor success in rural Africa, unless they are fruit trees (Ouedraogo, 2000).

In each parcel, the following volumes of “green” wood are determined for harvest (Ouedraogo, 2000):

- Firewood is harvested that has a diameter breast height (DBH) (*diametre à hauteur de poitrine* – DHP) of 10 – 25 cm;
- The DBH is greater than 25 cm; and
- The health of the forest in the parcel is also determined, with sick/weak trees slotted for harvest.

Certain species are protected. Once a parcel has been harvested, no livestock is allowed in for 18 months in order to allow the trees to grow large enough that they cannot be destroyed by grazing/browsing livestock, which can eat the shoots of young seedlings/coppicing plants when they are too small (Ouedraogo, 2000).

One obvious need is the formal training of youth from the village in forestry management so that full devolution from government can actually be negotiated between the community and government.

9.8.10 Community Forest Management, Tanzania

Barrow, *et al.* (2000) describe similar natural forest management programs in Tanzania:

“Potentially they will own the forest, as long they can show that they can protect the area from damaging use and degradation. Village forest management plans and detailed rules about forest use have been developed and agreed, and are enforced through village forest watchers”.

This provides a

“practical and low cost natural forest management approach for Tanzania, which can be used both on public lands and reserved forests. It goes beyond the sharing of forest products to devolving authority for management to the villages concerned...Precedents are being set for collaborative forest management through village government on non-reserve forestlands, by gazetting them as local authority forest reserves (e.g., in Babati District, see Wily, 1995; Wily & Haule 1995 both *In:* Barrow, *et al.*, 2000). The district governments appear, however, to retain management control. The relationships between the forest users, village and district government under such scenarios remain unclear. Experience from other countries (Hobley, 1996 *In:* Barrow, *et al.*, 2000) suggests that the creation of local authority forest reserves or village forest reserves, where power is vested in district and village government (respectively), may not lead to sustainable and equitable forest use (Nurse & Kabamba 1998 *In:* Barrow, *et al.*, 2000).

Today, more than 500 villages directly own and manage forest reserves in five of the country's 20 regions. Another 500 or so smaller social units, even individuals, have recognized forest reserves. These figures, and the area under direct community management, currently more than 400,000 ha, grows yearly. Meanwhile, state/people co-management through joint management agreements is getting underway in four of the country's 500 government-owned forest reserves. The new forest law, under draft in 1999, will provide legal recognition of a series of forest reserves to cater for emerging and diverse ownership arrangements including reserves which are owned by individuals, groups, villages, local governments and national government... the Tanzanian state has taken community forestry on board not for purposes of social justice or compromise but as a resource management strategy in its own right. The main competing strategy as reflected in the new National Forest Policy, is encouragement towards the leasing of commercial forests to the private sector” (Wily, 1999 *In:* Barrow, *et al.*, 2000).

9.8.11 Emerging Community Devolution Model - Public/Private/Community Partnerships (PPCP's) - Mpembeni Community Conservation Game Reserve – Hluhluwe Game Reserve - South Africa

The following is taken from the SCI Africa Office Status Report, August, 2000 (SCI Africa Office, 2000b) compiled by the principal author. As a means of developing good neighbor relations with peripheral communities, the KwaZulu-Natal Nature Conservation Service (KNNCS) provides a share of all gate receipts to the ten peripheral communities surrounding the Hluhluwe Game Reserve, many of whom lost land in the creation of this reserve. In 1999, Rand 700,000 (US\$ 118, 644) was turned over to the communities. The *inkosis* (local Zulu chiefs) decided to reinvest this initial money back into a lodge within the reserve as a means of providing more employment for local communities. It is likely that in the future, money will be reinvested into community run enterprises (e.g., lodges, traditional villages, handicraft centers, etc.) on the newly created community-owned game ranch).

Meanwhile, through the efforts of the community KNNCS liaison officer Jabulani Mbhamali, the community learned about the potential of game ranches along the periphery of the reserve. This led to the request by the Mpembeni Community to have a portion of their land fenced up to the main fence of the Hluhluwe Game Reserve. Given the history of fencing, parks and game reserves in Natal in which many communities lost land without compensation, there has been an initial reluctance to see the periphery fence of the Hluhluwe Game Reserve pulled down. This may occur in the future once the community develops confidence that this time they are gaining, not losing, by fencing themselves into a park/reserve.

The relationship being developed between the KwaZulu-Natal Nature Conservation Service (KNNCS), the Mpembeni community and the private sector

is believed to be the beginning of the development of an adaptive model, which can be replicated elsewhere in South Africa. Already, neighboring communities, in particular Semi (2000 ha), Ngolotshe (5,000-8,000 ha) and the Hluhluwe Triangle (1,000 ha) are requesting participation. Eventually, this has the potential of resulting in the formation of a large community conservancy with the fences between them and the Hluhluwe Game Reserve pulled down as around the Kruger National Park, but all owned by the local Zulu communities. Of course, like most of these CBNRM programs, it has a long way to go, but unlike most, the people own their own land, and once the wildlife is on their land, it belongs to them.

Trevor Shaw,²⁹⁹ owner, and Nic Vaughn-Jones, the then manager of Zulu Nyala Lodge, took interest. Vaughn-Jones had worked in the old Natal Parks Board and maintained contact with his colleagues. When he heard about the desire of the Mpembeni community to get into game ranching, he and Shaw said “Why not? We want to give something back, help overcome the inequalities of the past. We have already developed three money making game reserves (Phinda, Zulu Nyala, Shaka Zulu Heritage Lodge), why not bring the same success to the local communities”.

Safari Club International (SCI) provided a no interest US\$ 10,000 loan to the Mpembeni community to fence a portion of their land, about 2,000 ha, into the main fence of the Hluhluwe Game Reserve. This money must be paid back within five years and will roll over in helping to fence other communities into the reserve. The idea, developed by Trevor Shaw, is, “Let’s give them a HAND UP not a HAND OUT”. The welfare dependency mentality developed by the donors in Sub-Saharan Africa must be broken. People must learn that they have the natural resources and, if properly managed, they can provide employment and finances to develop and uplift themselves.

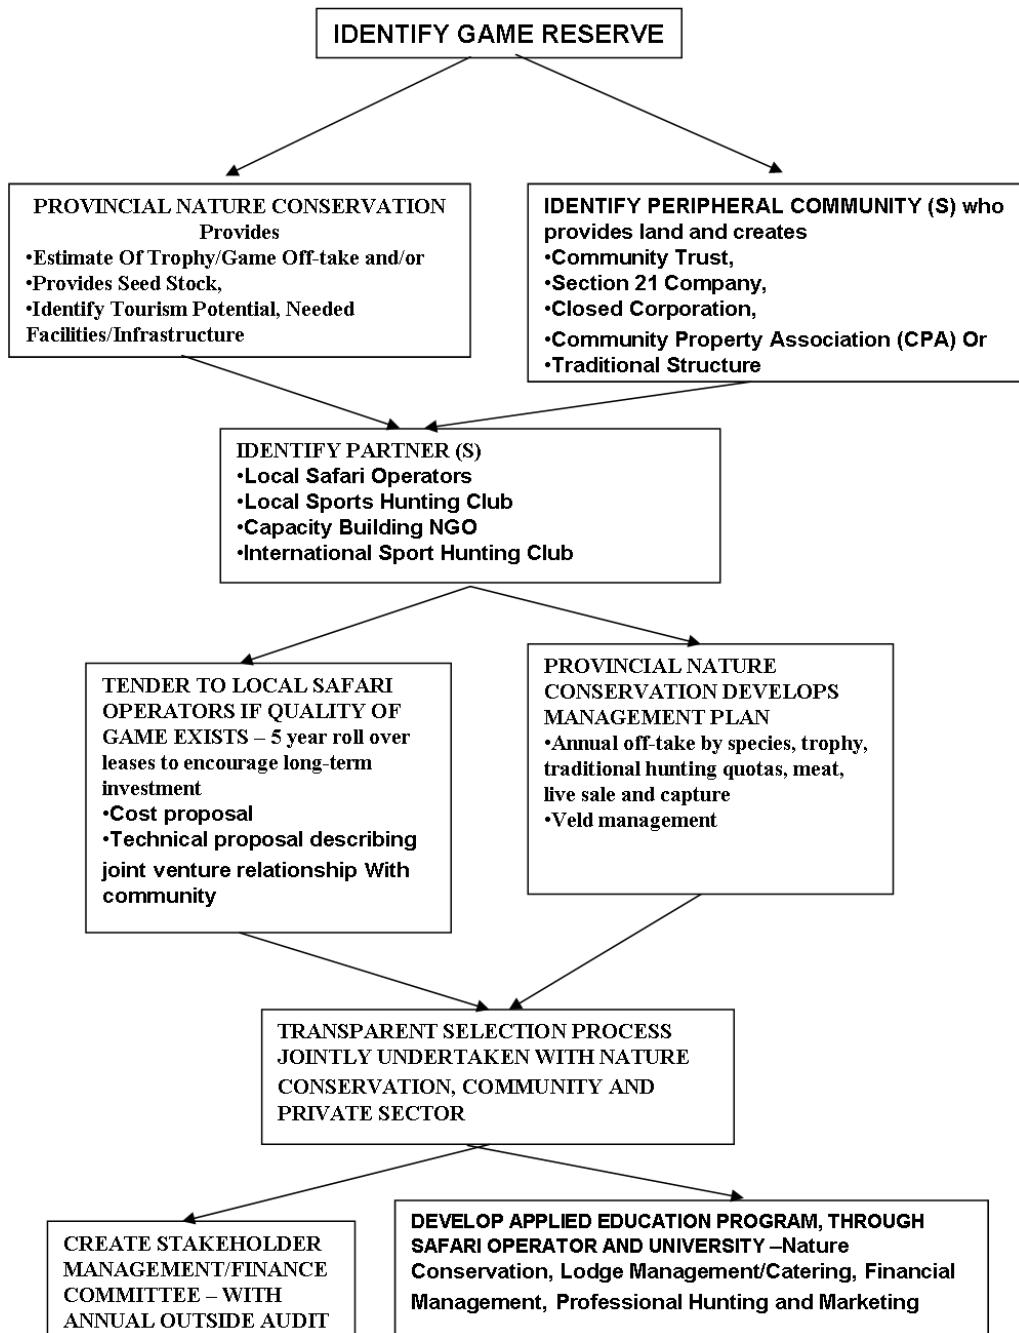

²⁹⁹ Trevor Shaw of Shaw Diamonds, P.O. Box 131, Ramsgate 4285, South Africa. Business: 27-11-484-1560, Home: 27-11-708-1969, shawdiamonds@yebo.co.za

PPCP Partnership. The public, private, community partnership (PPCP) works as follows: 1) the Hluhluwe Game Reserve provided seed stock (buffalo, nyala, impala, kudu, zebra, etc.) and a game ranch management plan, 2) the private sector provided the business plan, 3) SCI, overseas sporthunters, provided the seed money for fencing, 4) the community provided the labor to fence and 5) the community and private sector formed a closed corporation. The community insisted that this is a marriage and expect the private sector partner to be with them for the next five to ten years until they are able to stand on their own two feet, in essence to function as a mentor. The fact that the Mpembeni community will have hunttable buffalo will immediately provide them with access to the international market.

Based on this experience, the following model is emerging which may be adapted to each situation (Figure 9.7). The principal author has been unable to follow-up on this since leaving SCI as its African office manager in November 2001. However, through periodic contact with Jabulani Mbhamali and Nic Vaughn-Jones, he believes it is progressing.

The Mpembeni community is very fortunate to have a Catholic mission. Their school is well furnished, the principal, the *inkosi*'s brother, has his master's degree and the majority of the last class of school leavers passed their high school exams and earned degrees. It is believed that this may not be the norm in many of the rural schools and investment in primary and secondary education may be required, followed up by innovative on-the-job applied educational programs.

For full devolution to occur, some students must be sent off for tertiary education as described in Section, 9.8.2.3 Human capital, skills and knowledge. It is unclear how far this program has evolved as it is in its early stages of development.

Source: DeGeorges In: SCI Africa Office (2000b)

Figure 9.7: Possible public private community partnership leading to devolution, Mpembeni Community, KwaZulu-Natal, South Africa

According to De Jager (*pers. comm.*),³⁰⁰ the Mpembeni community program is going strong, with many other communities wishing to come on board. It also appears that the South Africa government is beginning to make development money available to rural communities to fence their areas, while provincial nature conservation authorities are providing wildlife “seed stock” (Collins, *pers. comm.*).³⁰¹ As with mentoring in agriculture (Chapter 5, Section 5.7.4.2, Land reform and South Africa), to be successful, a joint venture will be needed between each community and a white safari operator who will train the community and expose them to the market place so that in ten to 15 years they can begin running their own operations. The province of KwaZulu-Natal has written up “Guidelines in Community Conservation Reserves” with regard to establishing a process leading to full community empowerment and integration into the wildlife and hunting industry (De Jager, *pers. comm.*), while the Department of Environmental Affairs and Tourism of South Africa has developed similar guidelines at the national level (Collins, *pers. comm.*; DEAT, 2003). Communities are also requesting that traditional hunting with spears and dogs be legalized,

“to only see hunting with a rifle without the use of dogs as the only ethical form of hunting is a white liberal point of view” (RSA Community Organizations, 2005).

9.9 WHITE MOUNTAIN APACHES, LESSONS TO BE LEARNED FROM AMERICA FOR AFRICAN CBNRM

The following information was provided to the principal author during a visit to the White Mountain (Fort Apache) Apache Indian Reservation in June 2003 (DeGeorges, 2003b). Meetings were held with personnel of the Wildlife and Outdoor Recreation Division (W&ORD - formerly Game and Fish Department)

³⁰⁰ Stoffel De Jager, Natural Resources Trade Manager, Commercial Operations Division, Ezemvelo KZN Wildlife.

³⁰¹ Steve Collins, Transform Program, German Development Cooperation (GTZ), Hatfield, South Africa

of the White Mountain Apache Tribe: John Caid, director, David Kitcheyan, deputy director and environmental/information officer, Greg Dazen, Jesse Palmer, wildlife biologists, Chadwick Amos, field supervisor/law enforcement. This was the home of the famous Apache warrior, Geronimo. The White Mountain Apache conservation model should prove very valuable to Sub-Saharan Africa CBNRM (Figure 9.8).

The White Mountain Apache Indian Reservation was formed in 1891. It is located approximately three and a half hours northeast of Phoenix. Prior to the creation of the reservation, the White Mountain Apache roamed freely over a much larger area extending well north of the existing reservation and south into Mexico. Similar to group and cooperative ranches in Kenya, the creation of the reservation gave the White Mountain Apaches sovereignty over the land, but not their natural resources. The reservation is situated at between about 1,829 and 2,743 m (6,000-9,000 feet) above mean sea level (Mean Sea Level) and consists of alpine meadows and stands of ponderosa pine and Douglas firs. It is the key watershed that supplies water to the city of Phoenix.

“Located on 1.6 million acres (640,000 ha) of resource-rich land, the Fort Apache Reservation is known for its scenic high elevation lakes and over 500 miles (805 km) of cold streams, pristine lands and thriving wildlife – making it a popular outdoor destination area for visitors throughout Arizona and the southwestern United States” (Caid, 2000).

The Wildlife and Outdoor Recreation Division (W&ORD) has been in existence since 1978. Previously, most of its employees were white, but today they are all Apache, with the exception of the current director. The following lessons may be learned from one of the most successful indigenous people’s wildlife/resource management programs in the world.

9.9.1 Lessons to be Learned for Africa

- Communities may have to legally challenge land and resource tenure, going so far as taking the government to the highest court in the land;
- By integrating community needs into the management of wildlife, poaching can be significantly reduced;
- With proper management plans, land use plans and controls, overseas trophy hunting, traditional meat hunting and other consumptive (e.g., logging and fishing) and non-consumptive (e.g. canoeing, white-water rafting and skiing), resource use can take place within the same geographical area with no harm to high income generating trophy quality;
- “Profitability and conservation are not mutually exclusive and, in fact, can be mutually beneficial. For example, the profitability of tourism and outdoor recreation enterprises can be directly tied to the tribe’s competency in natural resource management and conservation;
- Strong institutional capacity enables tribes to exert their jurisdictional sovereignty more effectively and may even lead to new opportunities for the exercise of sovereignty;
- Tribal codes, regulations and policies gain acceptance and effectiveness when they reflect community values” (Caid, 2000);
- Minimal interference by federal and state government, other than decision support and technical backstopping, is needed;
- Conservation can help fund and subsidize other economic sectors that provide employment to community members at the household level; and
- University training of wildlife and fishery biologists and business managers is critical to achieving institutional capacity.

In the past, wildlife populations were decimated from over-hunting by tribal members and from commercial hunting by non-member white hunters, who sold the meat, skin and trophies, similar to the history of wildlife over the rest of the North American continent and over much of colonial Sub-Saharan Africa (see Chapter 3). The Merriam elk (*Cervus merriami*) was indigenous to the area but hunted to extinction by commercial hunters. Today, big game consists of re-introduced elk, Rocky Mountain Big Horn sheep (*Ovis canadensis canadensis*), pronghorn antelope (*Antilocapra americana*), mule deer (*Dama hemionus hemionus*), Coues (white-tail) deer (*Odocoileus virginianus couesi*) and black bear (*Ursus americanus*). Turkey (*Meleagris gallopavo*), javelina (*Tayassu angulatus*), cottontail rabbit (*Sylvilagus audubonii*), tree squirrel (*Sciurus* sp.), fox, coyote (*Canis lantrans*), duck, dove, pigeon and quail can also be hunted.

9.9.2 Land and Resource Ownership, Key to Success

Unlike most CBNRM programs in Africa, the White Mountain Apaches own their own land (e.g., as in Kenya) and their natural resources. In essence, they are a sovereign state (the reservation) within a state (USA). They feel that this is the key to their success. They have exclusive rights to manage their natural resources in the interests of their people, both economically and culturally. However, this has not always been the case.

As with most community programs in Africa, both state and federal governments decided how their wildlife and other resources would be used through top-down management (e.g., somewhere between “Management Against and Management for the People”). As in Africa, the White Mountain Apaches were “observers on the sidelines”, while Big Brother – state and federal government – were the players on the field. Decisions on how to use the resources were not always in the interests of the “members”, that is the tribal members living on the reservation,

often biasing access to the resource to “non-members”, mostly whites living off the reservation. Does this sound like Africa?

“Until the early 1980s, however, the Tribe had minimal management control over its abundant natural and wildlife resources. Although the Tribe had long possessed a Game and Fish Department, the Arizona Game and Fish department regulated all non-member hunting activities on tribal lands. The Tribe had little input into the State’s process of establishing non-member hunting seasons or setting harvest levels for reservation wildlife. By the 1970s, tribal managers had grown increasingly concerned that the State’s liberal issuance of big game hunting permits at below-market prices was irresponsible from a conservation standpoint. Further, the Tribe was missing out on a potentially lucrative source of income” (Caid, 2000).

Does this sound like Africa?

“Seeking to expand its jurisdictional control over its resources, the Tribe filed a lawsuit against the State of Arizona in the late 1970s. The issue ultimately found its way to the United States Supreme Court: in 1982, in a related case, *Mescalero Apache Tribe v. State of New Mexico*, the Court recognized tribes’ sovereign authority over the management of tribal fish and wildlife resources. This decision paved the way for the White Mountain Apache Tribe to institute its own management practices and to develop innovative, culturally appropriate recreation-based businesses. Building on its success in fisheries management – a program contracted from the Bureau of Indian Affairs (BIA) some years earlier – the Tribe established its wildlife management program through another contract with the BIA and focused on the development of various big and small-game hunting programs” (Caid, 2000).

As part of the agreement with the reservation, the tribes were given jurisdiction over their wildlife and fishery resources with the understanding that they be sustainably managed. Past practices of year-round hunting and no hunting quotas by species, which could negatively impact these resources, would give the State of Arizona the right to step in and re-take control. This has not happened.

9.9.3 Common Property Resources to Open Access and Back to Common Property

Similar to Africa, the White Mountain Apaches and other Apache tribes had traditional controls over the access to their resources in pre-colonial times. Wildlife was a “Common Property Resource” with controlled access by the tribal chief and elders for the good of the tribal community. Similar to Africa, at that time, human populations were low relative to the wildlife resource base. Tribal members traditionally hunted only for food. Certain species, especially the mule deer and bear, were “totems” with special spiritual significance to various clans within the White Mountain Apache tribe. Game was not hunted in the summer time, which coincides with females raising their young. Game provided both food and clothing. For instance, hunters were given five to seven deer per year to hunt for their family.

Similar to Africa, with the colonization of the USA by Europeans and the imposition of their systems of governance and management on the White Mountain Apaches, control over access to wildlife by the tribal community was taken away and placed under centralized control of the Arizona State government. What had been a “Common Property Resource” managed by the tribe to the benefit of its members became an “Open Access Resource” belonging to the general public, both tribal members and non-members (whites), managed by the state, which had little control initially over the actual management of the wildlife or, as noted at a later date, appeared to be quite liberal in its provision of quotas to non-tribal members (outsiders), often to the detriment of the game. Early on in this history, as in Africa, commercial white hunters devastated the game. The White Mountain Apaches, like many African cultures who had lived in harmony with their wildlife resources, lost complete power over controlling access.

As in Africa, access to game became a free-for-all by both members and non-members. The traditional controls, which had existed, were gone and the new controls were inadequate. As in Africa, the attitude of tribal members was, “We had better get it while we can, since if we don’t the non-members will take it”, a typical “tragedy of the commons”.

Wildlife populations were heavily pressured and some species such as the Merriam elk were wiped out. Mule deer populations were over-harvested and their populations were greatly reduced.

It was this situation that spurred the White Mountain Apaches to fight to regain access to control over the management, utilization and right to benefit from their resources. Unlike the White Mountain Apaches and other tribal groups in North America, most CBNRM programs in Africa find Africans having neither title to their land nor their resources. Most of Sub-Saharan Africa today is in a situation that the White Mountain Apaches and other tribal groups were in prior to 1982. Most CBNRM programs are top-down with strong interference by outsiders, including central or local governments, NGOs linked to Western donors and white tourism and safari operators, who make the majority of the profits from the “resources”, especially wildlife, but also timber in Sub-Saharan Africa’s tropical lowland hardwood forests (e.g., in Gabon, Cameroon, Congo Brazzaville and the DRC), fish in many of its lakes/reservoirs (e.g., Kariba, Cahora Bassa, Victoria) and even minerals (e.g. petroleum, gold, diamonds, COLTAN, etc.). Little or none of this revenue reaches rural communities who live among this incredible wealth that is being expropriated by the national/international elite, while they remain poor and backwards.

It is likely that this will continue until local communities organize themselves to fight the legal battles that will be necessary to take back their lands and resources and/or as in Burkina Faso, central government realizes that it is incapable of managing resources on its own and decentralizes power to co-manage wildlife and forests, and/or devolves ownership over these resources to communities as has happened in Southern Africa on private white-owned farms.

Under the current devolution process, the White Mountain Apaches co-exist with their wildlife. Unlike the current conservation efforts in Sub-Saharan Africa, tribal members live with the wildlife on the reservation, as opposed to being separated from it. As in pre-colonial times, the White Mountain Apaches now have control over access to wildlife by both tribal members and outsiders (non-members). Anyone is welcome to access their resources but must pay for this right under a rigid set of rules and regulations as to quotas and sex/age of the game or fish to be harvested. This is required since the White Mountain Apaches have more people on less land than historically, resulting in a resource/population ratio that is low and requires more intensive management than in pre-colonial times. Given current and projected population pressures, this is where Sub-Saharan Africa must go - where the White Mountain Apaches are today and still evolving - regain ownership over their resources and begin intensively managing them.

9.9.4 Economic Benefits

Most of the money made on the reservation is from hunting the top trophy elk in North America, about 90/year from 12 management units. The demand is so high that they can sell these hunts for US\$ 12-15,000/trophy elk, plus another US\$ 3,000 if the trophy makes it into the Boone and Crockett record book that records the top hunting trophies of all time from North America. There is a three-year

waiting period once the hunter has paid US\$ 500 as a deposit. There is also one auction hunt/year with a minimum opening bid of US\$ 25,000.

For the 2002-2004 season, 18 “management bull elk” were being sold at US\$ 5,000 each. These elk can have antlers with no more than five points/antler. One Big Horn sheep is taken per year for about US\$ 40,000. Both guided and non-guided hunts are offered for non-reservation members for antelope, non-trophy elk, bear, turkey and chance encounters with mountain lion while hunting antlerless elk.

The W&ORD generates US\$ 700,000 per year in net profits from its hunting and fishing programs. Of this, US\$ 200,000 is used to budget the W&ORD management and anti-poaching activities. The W&ORD staff finds this inadequate to drive their program. Many must use their own vehicles in their fieldwork and the staff is stretched very thin on the ground. For instance, only six staff are employed to cover anti-poaching on the 640,000 ha (1.6 million acre) reservation.

The remainder, US\$ 500,000, goes to the tribal council, which is made up of 11 members elected by the tribe, the majority of whom lack a university education and who are wary of tribal members sent out into what some call “the real world”, the “white man’s world”, and who come back to the reservation. It is likely that Project Noah students³⁰², who come from rural areas in Sub-Saharan Africa where wildlife is important, will experience similar problems in re-integrating and being accepted back into their communities on completion of their education.

As with the White Mountain Apache conservation program, the key to success will be taking Western concepts on resource management adapted to the African

³⁰² A scholarship program for rural Africans from important wildlife areas through the Department of Nature Conservation, Tshwane University of Technology, South Africa funded by Shikar Safari Club and private benefactors.

continent (e.g., university training in South Africa) and integrating them into traditional social and management systems. In Sub-Saharan Africa up until now, these Western systems have been imposed on rural people and have for the most part been rejected.

Similar to many of the CBNRM programs in Sub-Saharan Africa, one problem with the income generated from the White Mountain Apache hunting and fishing program is that there is no transparency or accountability with the US\$ 500,000 annually given to the tribal council. W&ORD staff believes that as the education of tribal members improves and more professionally trained university graduates slowly take over the tribal council from the older generation, this will be addressed. As in Africa, the lack of an annual audit opens the door for corruption and mismanagement of these funds. This has been a major problem for CBNRM programs in Sub-Saharan Africa.

As in many CBNRM programs in Sub-Saharan Africa, most tribal members on the White Mountain Apache Reservation do not even know the significance of the hunting and fishing program to their lives. There is an obvious need for a public relations program to sensitize them to this and for the tribal council to show its members how this money is used to their benefit. However, what they do know is that, within the law, they all have the right to hunt and fish for cultural and subsistence purposes.

Furthermore, if one assumes an average family size of six, this would result in US\$ 250/head of household that could be distributed from the US\$ 500,000 generated for the tribal council each year. Similar to Africa, the resource base and the potential income it can generate relative to the human population on the reservation is very low. This income will not significantly impact the livelihood of the average household and is likely best used to provide “common property

benefits” such as schools, scholarships for a university education, etc. There was no talk of household distribution of benefits.

Currently, the hunting and fishing program is the only economic sector operating at a profit. The labor-intensive timber program lost US\$ 8.9 million in 2002 and the ski and casino programs are running in the red. Thus, hunting and fishing are helping to subsidize these other programs, some of which could be restructured to make a profit, but which would be politically unacceptable, as this would mean putting many people out of work in a situation where unemployment is already high at 85%. One could argue that the self-esteem gained by being employed may be as important as making a profit for the psychological well being of both the individual and the community. In other words, hunting is subsidizing other industries that are labor intensive and which provide livelihoods at the level of households – a major shortcoming that CBNRM must overcome.

This leads the W&ORD staff, which was interviewed, and the principal author, who has analyzed CBNRM programs in Sub-Saharan Africa, to conclude that integration of tribal members and their cultural needs into the management of fish and wildlife is as important as economic benefits in obtaining a “buy-in” to conservation on the White Mountain Apache Indian Reservation. This has meant allowing tribal members to hunt, fish, log, etc., but under a set of controls that will be described below, while at the same time creating labor intensive industries, even if they are subsidized by revenue made from wildlife.

9.9.5 Education

Similar to Sub-Saharan Africa, the White Mountain Apaches were compressed onto a small piece of land compared to colonial times, the majority of former tribal land being reserved for European settlers. As in Sub-Saharan Africa, the

current population on the reservation is expanding rapidly, having grown from 8,000 to 12,000 people between 1995 and 2003 (in eight years). People are poor. Very few people on the reservation have a chance to go beyond high school. This appears to be from a combination of opportunity and a cultural stigma against those who leave the reservation to study and live in the “white man’s world”.

Recently, the first Apaches have graduated from university in natural resources management, one in fisheries and the other in wildlife biology.

The tribal council as well as W&ORD now offers scholarships to anyone wanting to study at the university level so this should help the reservation achieve a critical mass of educated people in the near future. One problem is that compared to the salaries offered off the reservation in the “real world”, salaries for university graduates on the reservation are very low, a disincentive for many to return to the reservation on completion of their studies. For instance, David Kitcheyan’s son, who is the first university trained fishery biologist from the reservation, has opted to work for the Arizona Fish and Game department where salaries are significantly higher.

9.9.6 Integration of Social and Cultural Needs into Management of Wildlife and Fish

“The W&ORD understands that community support is directly tied to the effectiveness of its work. The Division actively seeks elder involvement, largely through an elder’s advisory board, which has led to the Tribe’s list of sensitive species being even broader than those of the state or federal government. Another example is the W&ORD’s approach to managing tribal citizens’ hunting. In the late 1980s, the W&ORD established a separate harvest system for tribal citizens, which provides subsidized game tags, sets aside hunting areas on the reservation, and designates special seasons for big game hunting. Moreover, tribal member hunting fees support

the W&ORD's Conservation Fund, which in turn supports hunter education, a 'report a poacher' program and a college scholarship program for tribal members pursuing degrees in fields related to natural resource management. Clearly, these efforts to reach out to citizens and to embrace their ideas, needs and cultural connections to natural resources, not only improve program management, but also citizens' acceptance of W&ORD's activities and help ensure program success" (Caid, 2002).

As in Sub-Saharan Africa, not everyone in the tribe is a hunter. There are an estimated 3,500 tribal members who hunt and probably more who fish. It is estimated that about 200 tribal members are trophy hunters, mostly the younger generation ranging from 25-35 years of age. Tribal members have been formally integrated into the management of the game and fish on the reservation, with quotas based on seasons, management units, age and sex (Table 9.20). This is much different from most Sub-Saharan African CBNRM programs, which have tended to take an approach that "meat and money" will suffice to obtain a "buy-in" to conservation, but have ignored cultural, religious and spiritual ties to wildlife by the local community. Just as importantly, the White Mountain Apache hunting conservation model demonstrates that the best trophy elk hunting in North America can accommodate meat hunting and even some tribal member trophy hunting without adversely impacting high-paying trophy hunters from outside the area. Logging by tribal members and fishing by tribal and non-tribal members also are undertaken, indicating that a conservation area can be sustainably managed for multiple uses of its resources for both economic and cultural purposes and still produce healthy game populations including the top trophy elk in North America.

Table 9.20: Proposed WMAT 2003-2004 tribal member hunting quotas

GAME	SEASON DATES	BAG/Person	PERMIT COST U\$S	NUMBER OF PERMITS	CHANGE FROM 2002-3003
WHITETAIL DEER	Dec 6/03 – Jan 4/04	1 Buck	20	720	-15

As in Sub-Saharan Africa, given the poverty and cultural ties to nature, multiple use appears to be the best way to manage such areas as a means of getting a “buy-

in" from society for conservation. Does the African subcontinent need parks and hunting blocks that are exclusion zones surrounded by poverty and which are rich in a multitude of resources that might help overcome this poverty? It will be observed that the four of the hunting management units for tribal members are the same as the respective non-member hunting areas. However, eight of the 12 management units are reserved exclusively for non-tribal high-paying trophy hunters. Thus, land use planning becomes integral to multiple-use management of an area. Also, of importance to the pride and dignity of the White Mountain Apaches, and relevant to Sub-Saharan Africa, is that non-tribal sport hunters are guided by Apaches, with the exception of mountain lion that is guided by whites with their packs of hounds.

No hunting license is required for small game or fishing by tribal members. Small game includes cottontail rabbit, tree squirrels, quail and dove/pigeon, blue grouse and waterfowl. Migratory game such as dove, pigeon and waterfowl require purchase of federal migratory bird stamps. Small game may be hunted reservation-wide by tribal members. Non-member hunting of small game is more closely regulated.

In negotiating the hunting season with the tribal elders, an early mule deer season has been established for people 55 years and older who traditionally did not hunt during the mule deer rut, claiming the meat is not as tasty. Tribal elders 55 and older can hunt turkey, cow and spike deer for free without a license. Key policies that demonstrate the attempt to integrate the needs of local tribal members into the management of the area include:

- Affordable costs for game shot for meat;
- High quotas in populations of game needed for meat;

- Quotas for recovered well developed populations of elk, cow and spike buck (young males) provided as both a management tool to keep the population under carrying capacity so that it continues to “breed up” and for habitat management, as well as a source of meat for tribal members;
- A special deer season as requested by elders, recognizing their traditional beliefs;
- A special quota “junior raghorn” for young hunters under the age of ten to 16 years of age;
- Diversification of hunting weapons, both archery and rifle;
- Small game hunting for free;
- Limited quotas and high trophy fees for tribal trophy hunters who are few, keeping most trophy animals for non-tribal members – white sport hunters coming from outside the reservation as a means of generating wealth for community development; and
- A limited quota by lottery “drawing” for tribal members for highly desirable trophy species.

It should be noted that a large effort is made in producing game as an important source of protein. As in Sub-Saharan Africa, the majority of tribal members are very poor, living a subsistence lifestyle. Thus, hunting provides a very important and significant portion of their diet and also allows tribal members to fulfill cultural needs.

Due to these efforts, the needs are met of the approximately 3,500 tribal members out of 12,000 who hunt. It is estimated that as a result of these efforts 95% of the game is harvested legally. Unfortunately, in Sub-Saharan Africa, very few conservation programs manage their game for both trophy hunting to gain income and meat as a source of protein to be harvested legally by traditional hunters. Most African CBNRM conservation programs allow only trophy hunting by

outsiders (rich whites from overseas), providing a limited amount of meat for the community. Since only 2-5% of the game population is harvested for trophies in Sub-Saharan Africa, another 10-25% of most game, depending on the species, could also be harvested as a source of meat and of course this is done clandestinely by traditional hunters so that management of the resource is precluded. Of course the more intensive the management, the more biological and habitat information is needed in order to assure that management decisions maintain the sustainability of both trophies and meat.

9.9.7 Poaching

The W&ORD has six members involved in anti-poaching to control the estimated 5% illegal game off-take. A “report a poacher” program exists, though the W&ORD staff says that most people will not report “their own” since the reservation is a small tight knit community and this can cause social unrest and friction. They will report “non-member” poachers. If we could get to this point in Sub-Saharan Africa, with community members being allowed to legally hunt, fish and harvest “managed resources” so they do not have to poach, *voilà*, wildlife would recover in leaps and bounds and be abundantly available for economic and cultural purposes. On the White Mountain Apache Reservation, “non-member poachers” are prosecuted civilly by the tribal justice system and fined. For illegally harvested elk, the non-member violator is charged US\$ 30,000, which is two times the trophy fee paid by non-member sport hunters. Additionally, they are turned over to the USFWS and prosecuted for a “Lacey Violation” for attempts to transfer game across international boundaries (from the reservation into the USA). This is a felony and can result in a major fine, a loss of voting rights and the right to own firearms, as well as a jail term.

For Sub-Saharan Africa, as communities take over management of wildlife areas, similar problems will exist, especially arresting or “snitching” on community members who break the law. However, what is very important based on the W&ORD program is that 95% of the poaching problem can be solved if the local community’s needs are integrated into the management of the area (both hunting and gathering) so that they can have legal but controlled access to the resources. In turn, by turning wildlife into a “Common Property Resource” which community members feel belongs to them, it will be in their interest to collaborate with both community anti-poaching teams and wildlife departments to prevent outsiders coming in to take and abuse “their” resources. The “5%” can be dealt with by government anti-poaching teams and/or creating community-based teams.

Nonetheless, the key to note here is that eliminating the “95% poaching factor” is not dependent on how powerful a police/anti-poaching force that can be manned but on rural people living with wildlife and their needs being integrated into the management of the area. To repeat once again, the White Mountain Apaches have only six people to conduct anti-poaching, an impossible task if it was illegal for all Indians to hunt and fish and everyone poached. This success can be extended to much of the USA, where “hunter hotlines” are used by game departments to help control poaching. In America, hunters and fishermen pay between 70-90% of the annual state game department operational fees. In addition, federal taxes on hunting products (Pitman Robertson Fund) and fishing gear (Dingell Johnson Fund) go to state game departments for game and fish research and habitat management, which helps not only improve game but protects endangered species and improves habitat and thus biological diversity. In Virginia, there are many areas where there is only one game warden/two counties (equivalent to two districts, provinces or prefectures in Sub-Saharan Africa), and it is the “eyes and ears of the warden”, the common citizen, who sees the game and fish laws to his benefit and it is thus in his interest to call a toll-free hunter

hotline number to warn game wardens when the “5%” break the law. Thus wildlife in America, as on the White Mountain Apache Indian Reservation, is seen as a “Common Property Resource” and it is in the interest of the country’s hunters and fishermen to stop the illegal off-take of “their” natural resources. There is no reason to think that this same process cannot work in Sub-Saharan Africa.

9.9.8 Monitoring

Wildlife monitoring is a tool to assure sustainability of game off-take. Wildlife monitoring is a key component to the success of the White Mountain Apache wildlife management program. The following monitoring takes place:

- Hunter questionnaires/report forms look at hunter success/effort, trophy quality and field observations; and
- Annual surveys look at population trends, “up, down, stable”
 - Annual aerial survey look at population trends and sex ratios in January when snowfall concentrates game;
 - Summer transect counts look at trends in recruitment and age ratios;
 - The aging of elk is determined by cimentum ring analysis of the teeth;
 - Trophy quality for elk is determined;
 - Habitat quality such as pasture/browse quality, climate, fires is assessed; and
 - Poaching is controlled.

The White Mountain Apache Reservation is broken down into a number of management units. There are no core protected areas. Similar to the Selous

Game Reserve (SGR), based on the collection of biological and other data, the entire reservation is hunted, fished and logged for its timber. Yet it consistently produces the top trophy elk in North America.

It should be noted that unlike Sub-Saharan African game, elk and deer drop their antlers every winter and then grow them back beginning in the spring. To some degree, trophy quality can vary from year to year among these cervids depending on rainfall and in return, browse and forage. In Sub-Saharan Africa, game does not shed its horns. Horns increase in length and basal diameter each year until old age when growth stops and they begin to “broom down”. Thus in a given management area in Sub-Saharan Africa, there can be a direct correlation between trophy quality and age, whereas this is more variable among North America’s cervids (deer, elk and moose). It is believed that trophy quality trends for Sub-Saharan African species may thus be a better indicator over time of successful management of game for economic and ecological purposes. A decrease in trophy quality over time for Sub-Saharan African game can be an indicator that various factors (drought, disease, unrealistic quotas, poaching, over-grazing by livestock, etc.) may be influencing game populations, enabling the wildlife manager to take mitigative action prior to an economic (poor trophies for hunters) or ecological (population crash) crisis being reached.

It is important to note that W&ORD does not try to obtain total numbers in this vast extensive area, which would have high standard deviations making establishment of precise off-take quotas based upon “total counts” alone very questionable, such as a 2% offtake of the annual population of a given species for trophy quotas. Rather, all of this biological data, as well as social inputs from the tribal members, are used to set trophy quotas for economic and social purposes and meat quotas for socio-cultural needs. Then these off-takes are monitored; this basically is “adaptive management” in full use.

9.9.9 Animal Rights and the White Mountain Apache Reservation

An animal rights group promised to pay the amount that would be lost on the reservation to stop all bear hunting. This was turned down, as wildlife and hunting are both an economic and cultural resource. This would have placed the reservation wildlife management program back under the control of non-members, something the proud people of the White Mountain Apache Reservation want to avoid as much as possible.

The Defenders of Wildlife, an animal rights group, also offered to pay for each livestock killed by the Mexican gray wolf being introduced. The problem in determining wolf kills is often difficult, since by the time the carcass is found it is often highly decomposed. The W&ORD staff is wary of all animal rights groups. African communities and governments need to take this lesson into account when considering taking “handouts” from Western NGOs and donors.

In closing, Marks (2005 *In:* Lyman & Child, 2005) may best sum up where conservation needs to go,

“people’s behavior, on all levels, is part of and shaped by wider social, economic, and political forces. Though recognizing these interdependencies, I remain convinced that the integration of environmental management, governance, and wealth must begin at the village level, where local people merge ideas and behavior into sustainable livelihoods. Such local processes must become the basis upon which incentives, policies, and management programs are designed and implemented for real community-focused conservation to materialize”.

This comes down to governments letting go of control over land and resource tenure, thereby empowering local communities to take back these resources and integrate their socio-cultural values into them and thus to gain concurrent benefits.

9.10 CONCLUSIONS

Community-Based Natural Resources Management (CBNRM) is a very emotive subject, with pros and cons being debated within and between the sustainable use and animal rights movements. Most programs have tended to be driven by NGOs and Western donors, though the original Sub-Saharan African program, CAMPFIRE, was designed by Zimbabweans to address the inadequacy of centralized management over the illegal off-take of wildlife by alienated rural Africans. It was, however, eventually hijacked by the U.S. government and prevented to date from achieving full devolution (ownership of land and wildlife by rural communities) due to the political turmoil of radical land reform beginning in 2000.

CBNRM is a dynamic process, which has the ultimate goal of leading to the devolution and empowerment of rural communities to take back their natural resources and receive direct economic and cultural benefits from their sustainable management. Most CBNRM programs tend to still be too top-down, with too much outside interference by governments, which are reluctant to devolve final ownership and control over these resources to communal management institutions. The government and other middlemen (tourist and safari operators and NGOs) have often placed themselves in between the rural communities and their resources, making it difficult for communities to significantly benefit from sustainable off-takes. CBNRM is said to be outside the park estate, but we are already seeing communities such as the Makuleke of South Africa taking back portions of the Kruger National Park. It is likely, over the next few years that significant portions of Kruger will return, through land claims to rural communities. There is no reason why many hunting areas and some parks should not be restored to their rightful owners, the peripheral communities, initially with heavy state and private sector support off which the community can be weaned as

it develops experience and self-assurance in its ability to sustainably manage and market the resources in these areas.

Most communities also have inadequate numbers of university trained youth in such diverse fields as wildlife management, business, accounting and marketing to be able to both manage and market their resources, as well as manage the somewhat institutionally complex structures (e.g., trusts, Section 21 companies, etc.) imposed on them by the NGOs and donors. Likewise, because most communities are illiterate and have little idea as to the value of wildlife and other resources, they are often taken advantage of by governments and the private sector, being given an inequitable share of the profits gained from marketing their resources. Developing linkages to the market place is one of the biggest constraints to communities becoming autonomous over their wildlife resources.

Until the issue of tertiary education is addressed, these other stakeholders will continue to interfere in the running of communal institutions and the management of their resources. Ultimately, the goal for rural communities should be maintaining the ecological integrity of key natural areas that have a comparative advantage as a land use both ecologically and economically, while creating community-owned companies so that the majority of the net profits stay in the rural areas serving as both a catalyst for development and to educate rural youth (e.g., major scholarship program for university and technical training) to compete in a global society. This will take pressures off the overly pressurized rural resource base, as most will move to urban centers. This is a major obstacle to success.

As noted, CBNRM institutions tend to be designed by outsiders and imposed on communities. Although many atrocities were committed in the New World by the *conquistadors*, the one wise, but terrible move they made in conquering the indigenous people of the Americas was to raze the temples of the Mayans, Aztecs

and Incas. However, they left the temple foundations on which they built their cathedrals so that the local people had something they could relate to in the adoption of Catholicism and this new culture imposed on them. If you visit the cathedral in Mexico City today, you will see at the base, carved stones of Aztec origin - that of a former pyramid that stood at this site.

For instance, as is evident from the case study of the Dozo hunters of Burkina Faso, the hunting guilds are still there. The community has chosen them to manage the game reserve with oversight by the greater community. This is an existing institution dating back 100s of years to the Empire of Mali that was weakened by colonialization and the last 40 years of independence. Such guilds and other indigenous institutions existing across the continent have been ignored, as Western controlled donor money prefers to create institutions “pleasing to their eyes”. Where such traditional institutions exist in Africa, we need to take advantage of them. We do not need to try and create another failed institution based on our Western ideals. We do not need to tear the temple down to the bedrock and start all over. Colonialism, though unwillingly, left behind a foundation for this “cathedral of conservation”, in this case the hunting guilds or other traditional structures that are accepted by communities. We need to build on existing institutions such as hunting guilds or the *n!ore kxausi* resource managers/structure of the Bushmen and re-empower them to take control of managing a resource – wildlife and other resources - on which their entire psychic is based. The majority of rural Africans also depend on wildlife for survival at both subsistence and economic levels. In the case of wildlife, hunters are the best conservationists in America and Europe and the authors believe given half a chance, along with empowerment and education, African traditional hunters will fulfill a similar role.

On the other hand, the human population pressures are so great today in much of rural Sub-Saharan Africa that the extensive management systems of the past (e.g., hunting guilds, controlling access through elders or *chef de terre*, taboos, totems, transhumance, etc.) need to be integrated into more intensive management systems (e.g., wildlife and trophy quality monitoring, fire management, anti-poaching, estimates of vegetational carrying capacity and off-takes, borehole management, etc.). This is why we need some youth from the rural communities trained up in our Western management systems and then planted back into their communities to integrate the old and the new, thereby getting the best of both worlds. But we do not need to scratch out all of the past; some of the past systems and institutions have merit, if for no other reason than providing a continuum in social identity among the local people and for that alone they need to be the foundation from which we build a modern conservation ethic.

We must all be honest with ourselves that even if we could triple or quadruple income going to communities, the amount at the level of households or individuals is so low that there is just no way that “meat and money” alone will change rural Africans’ attitudes towards their natural resources.

The fact is that minority pastoralists (e.g., the Maasai) and hunter-gatherers (e.g., the Bushmen and Pygmies) live in specific geographical areas where wildlife, among other important resources, is found, which in reality is no different from American Indians living on a reservation. The fact is that in many cases, the governments have and are taking actions detrimental to their well being such as making them sedentary through group ranches in Kenya, as is the case with the Maasai, or forcing them to leave their traditional territories that are consequently turned into parks and protected areas, such as the Bushmen being forced to leave the Central Kalahari Game Reserve (CKGR) (see Chapter 3, Section 3.9.2, Eco-Genocide and the San of the Central Kalahari Game Reserve (CKGR), Botswana)

or the Pygmies losing access to 70% of their forests declared as parks and safari hunting areas in Southeastern Cameroon (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the Dobi Dobi, More Parks and Protected Areas). The areas they are left with are too small to support them carrying out traditional livelihoods while using extensive approaches to manage their natural resources. In the 21st century, this, along with population increases, will condemn the majority to abandon these traditional lifestyles. CBNRM may permit a small percentage to continue living in these rural areas, but even they will be required to more intensively manage their resources in order to support more people in smaller areas.

This tells us that conservation on its own is doomed to failure. While wildlife may be a crucial component of rural livelihoods, diversification into other activities, such as logging, handcrafts, mining, etc., will be critical, as with any developed society. Realistically speaking, some current wildlife areas may give way to critical food production. We are not going to save it all. Areas critical to wildlife need to be identified and compared to see how they will compete with other land uses. Furthermore, these activities must fit into a larger land use and development plan nationally, regionally and continentally, if the rural people and their wildlife are to have a reasonable future. As we can see from decreasing fallow (Chapter 5) and the disappearance of transhumance (Chapters 5 and 6) on the continent, the limited benefits/household from CBNRM should send up a “*RED FLAG*”. There are too many people out there, the resources are being mined, habitat is disappearing and CBNRM is only part of the solution, not “the solution”. In essence, CBNRM needs to be demystified and depoliticized to the general public interested in solutions to African conservation and development.

Like it or not, conservationists are going to have to stop being so narrowly focused. They are going to have to open up and reach out to other disciplines and realize that what they are doing must fit into a larger picture of “pre-industrial

societies”, as President Yoweri Kaguta Museveni (1997) calls them, becoming urbanized and industrialized to take the pressure off the rural resource base. Sub-Saharan Africa has exceeded the carrying capacity of the resource base to support the majority of the people living subsistence life styles. This means that the West and/or South Africa should provide the rest of Sub-Saharan Africa with the technologies to transform its raw products in Africa as a means of obtaining added value and employment; products should not be exported in the raw and transformed in U.S., China, India, Japan or Europe. It also means that the leaders of Sub-Saharan Africa should close their Swiss Bank accounts and invest profits from these resources back into their countries and their people. It means that these resources should be given back to the communities who live among them. It means that more of the profits should go directly to the producer communities so that money can exchange hands many times, creating a five to seven times knock-on effect on the economy as they turn from subsistence to consumer societies that stimulate the demand for more manufactured products, many of which can be produced on the continent. It means that there should be a major emphasis on education, preparing the majority of today’s rural youth to compete in a global society in urban centers, while teaching those who choose and/or are able to make a livelihood in a rural setting about intensive management of soils (e.g., use of fertilizers, pesticides, green manure, nitrogen fixing legumes, crop rotation, GMOs, etc.), of water (e.g. borehole management), of forests and of wildlife. In some cases, this means relearning lost traditional knowledge from the elders and integrating it into modern management principles. Wake up Africa! If you were the “United States of Africa” you would be the richest country in the world, but as individual countries and mismanaged corrupt economies, often with non-representative governments, you are among the poorest even though you may have the richest resource base in the world. Africa, only you can turn it around. The world will follow your leadership, but you must take the first step.

One thing that we can learn from the White Mountain Apaches in the USA is that the integration of spiritual and cultural needs of rural Africans into the management of their resources is just as important as monetary benefits from wildlife. Integrating traditional hunters and other resource users into the formal management of their natural resources so they will not have to poach is critical. On the White Mountain Reservation, 95% of the wildlife is harvested legally, since no one has to poach, while in Sub-Saharan Africa, 95% of the wildlife is poached since few people in rural areas have legal access to wildlife let alone other resources. Like the White Mountain Apaches, many rural minorities in Africa may have to take their government to court over ownership rights to wildlife. The fight of rural people for their resources will increase in the 21st century. Certainly, creating more Sherwood Forests that alienate Africans and compress them into smaller and smaller unsustainable areas is not going to save Sub-Saharan Africa's natural resource base. Like the translocation of elephants from over-populated areas to avoid culling, parks and protected areas provide a short-term solution, which will be engulfed by a wave of human poverty. Addressing these human issues, especially working with Africans to live with and sustainable manage their natural resources as the White Mountain Apaches are doing, will be the only way to solve conservation and biodiversity issues in the long-run: taking a step backwards in re-empowerment to go forwards.

Finally, the creation of an urbanized middleclass, once people have been removed from living a survival mode, will enable Sub-Saharan Africans to start developing a modern conservation ethic that meets both rural and urban needs. Like it or not, in 50 years, this is where the majority of Africans will live. If this process of urbanization and industrialization fails, the subcontinent, its people and their natural resources are heading down a slippery slope, from which they will not return, an Armageddon where anarchy reigns and basic necessities such as food and water are fought over as diamonds, gold and oil are today.

Chapter 10

10.0 CITES AND THE ESA, NEO-COLONIAL IMPACTS ON SUB-SAHARAN AFRICAN CONSERVATION

“The powerful members of CITES are the very same nation states that systematically discriminated against the encapsulated indigenous populations, and they continue to appropriate indigenous property according to remnant imperial doctrines held at law” (Langton, 2003 *In: Adams & Mulligan, 2003*).

“*Homo sapiens* has become the most dominant species on Earth. Unfortunately, our impact is devastating and if we continue to destroy the environment as we do today, half the world’s species will be extinct early in the next century...biological diversity is in the midst of its 6th great crisis, this time precipitated entirely by man...And we, *Homo sapiens*, may also be among the living dead” (Leakey & Lewin 1995).

The next four chapters of this book show how international neo-colonial policies by former European colonizers and the West in general are still at the heart of negatively impacting Sub-Saharan Africa’s economies and the conservation of natural resources.

This chapter discusses the Convention on International Trade in Endangered Species (CITES) and the U.S Endangered Species Act (ESA), demonstrating how they have become tools of control rather than cooperation by the West towards Africa, with negative consequences for conservation and rural livelihoods.

The authors would like to thank John Jackson of Conservation Force³⁰³ for much of the background information and critique.

10.1 THE CONVENTION FOR THE PRESERVATION OF ANIMALS, BIRDS AND FISH IN AFRICA

Once the scramble for Africa was over, it belonged to everyone but indigenous Africans. Much of the wildlife, particularly elephant (*Loxodonta africana*), was depleted by the end of the 1900s (Bonner, 1993) (Table 10.1):

Table 10.1: African elephant populations early 1900s

COUNTRY	YEAR	NUMBER	SOURCE
Zimbabwe	1900	LESS THAN 4,000	Cumming, <i>pers. comm.</i>
Namibia	1900	300	Lindique (1995)
South Africa	1920s	120	Hall-Martin, <i>pers. comm.</i>

Source: DeGeorges In: African Advisory Board (2000).

As described in Chapter 3, the colonial masters of England, France, Belgium, Portugal and Spain in 1900 signed the first international conservation treaty, The Convention for the Preservation of Animals, Birds and Fish in Africa to save African wildlife for the exclusive use for hunting by royalty and upper class Europeans and for ivory. It prohibited shooting infants, females when accompanied by young and elephants with tusks less than 5 kg (11 pounds) each, with the goal of maintaining large enough numbers to continually meet the demand of the ivory trade. Its objective was also to protect elephant and wildlife in general from the Africans (Bonner, 1993).

Lion, leopard and wild dog were considered vermin. Leopard was taken off the vermin list in Kenya about 1930, since white settler farmers found that it kept down crop raiding baboons and bush pig populations. The hunting license system favored whites over Africans, since over much of the subcontinent, Africans could neither afford a license, nor were allowed to own a rifle (Bonner, 1993),

1949

while their traditional methods of hunting were outlawed, as described in Chapter 3.

As also described in Chapter 3, the belief was that if the Europeans had not brought their conservation laws to the African continent, all game would have disappeared. They were saving Africa from the Africans even though it was the Europeans with their firepower, modern medicine and pathetic environmental policies (e.g. confiscation of land for parks, game reserves and settler farms compressing Africans onto unviable and often marginal land masses) that resulted in the slaughter of wildlife for ivory, hide and meat and the loss of habitat across the continent. The concept of integrating traditional hunters and other resource users into the management of wildlife was not yet thought of. Africans were forced to access wildlife clandestinely, while wildlife and other natural resources became open access, not managed very well if at all by either ever expanding communities or central governments.

10.2 AFRICAN INDEPENDENCE AND POACHING

As described in Chapter 3 of this book, with the independence of the African states beginning around 1960, the continuation of colonial laws and animal conservation infrastructure failed to any longer control poaching. Almost simultaneously, an overseas market opened up for elephant ivory and rhino horn in the oil rich Middle East and the rapidly industrializing East, resulting in increased buying power for its citizens.

Raw ivory went from US\$ 5.50/kg (2.50/pound) in 1970 to US\$ 132/kg (US\$ 60/pound) by the end of the decade. This resulted in an escalation in poaching. Kenya's elephant population fell from an estimated 167,000 to 59,000 between 1973 and 1977 (Bonner 1993). Leakey and Lewin (1995) place Kenya's elephant

1950

population at less than 20,000 by 1989. Even though the ivory trade was legal in Kenya, it is estimated that between 10,000 and 25,000 elephant/year were killed illegally. Under pressure from the World Bank, which was providing money for tourism, hunting was banned in 1977 and the sale of wildlife products was banned in 1978, neither of which stemmed the poaching of wildlife. In fact, many authorities believe that by taking safari operators, who had been collaborating with the game department to control poaching, out of the bush, elephants were opened up to even more indiscriminate slaughter. "If you leave your house empty, you can expect thieves to move in" (Bonner, 1993). President Jomo Kenyatta's wife, Mama Ngina, was the key figure behind Kenya's elephant poaching and ivory trafficking (Bonner, 1993). Parker (*pers. comm.*; 2004) says that there was never any hard evidence to support the claim of Mama Ngina's involvement. However, Kenyatta's daughter, Margaret, ex-mayor of Nairobi and sometime Kenyan representative to the United Nations Environmental Program (UNEP) was heavily involved in ivory dealings. Her company, the United African Corporation (UAC), exported a lot of ivory to China during the 1970s, with an estimate that in 1974 alone she could have exported as much as 73 tons of ivory representing over 3,000 elephants (Parker, 2004).

Uganda's elephant population under Idi Amin was virtually eliminated, while Tanzania lost 75% of its elephants between 1979 and 1989 (Leakey & Lewin, 1995). In the Selous Game Reserve (SGR), with the highest elephant population in Tanzania, elephant populations fell from 110,000 in the late 1970s to 55,000 by 1986 to as low as 30,000 in 1989 (Siege, 2000; Baldus, 2005 *In:* Baldus, 2005).

"Village poachers and game scouts did the shooting, but 'big people' - politicians, civil servants, business men and even hunting operators - masterminded the slaughter.³⁰⁴ This book is not the place in which to reveal the details and names, some of which are

³⁰⁴ Also known as *bwana mkubwa* (the "big people") (Baldus, 2005).

known, as many of these people are still alive" (Baldus, 2005 *In: Baldus, 2005*).

Due to the nation-wide anti-poaching³⁰⁵ operation called *Uhai* (life) (Baldus, 2005 *In: Baldus, 2005*), along with the development of the GTZ-backed Selous Conservation Program (SCP), by 2000, the elephant population of the Selous had returned to about 60,000 elephants due to natural population growth and behavioral changes, making them easier to count in the open (Siege, 2000). Tanzania's national elephant population declined from a high of 365,000 in 1977 to an estimated 53,000 by 1993, due to both poaching and a major reduction in range from 90% of the country to 50% through ever-growing human populations (GOT, 1993).

The International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU) African Elephant and Rhino Specialist Group reports that Africa's elephant populations dropped from just over 1,000,000 in 1981 to 700,000 by the late 1980s. They reported, "there can be no doubt, it is the (illegal) ivory trade that is reducing the population of the species most severely" (Bonner, 1993). While the principal author was living in Senegal, elephant poaching was so bad in the Central African Republic that trophy hunting for this species was closed in the mid-1980s. Leakey and Lewin (1995) place the drop in African elephants from 1.3 million to 625,000 between 1980 and 1989. They argue that what people failed to realize was that the sex ratios were being modified, as selective harvesting of mature males for their larger tusks skewed the 50% male/female ratios, males dropping to 22% of adults in Kenya and to less than 1% of adults in Tanzania. This disrupted mating patterns, greatly decreasing the likelihood of a fertile female (two to three days every three months) encountering a male at the right time. Once the big males were dispatched,

³⁰⁵ Most of the elephant poaching in the Selous had been stemmed by 1990 (Baldus, 2005 *In: Baldus, 2005*).

females were poached with the average tusk size dropping from 25 to 12 pounds. Many elephant herds began losing matriarchs, who pass on knowledge and provide social organizational structure to the herd.

While Ian Parker's 1979 ivory trade study indicated a population of 1.3 million elephants, ivory exports from 1976-1978 represented less than 5% of all African elephants, which in theory would be sustainable if Africa's elephant populations were stable, which they were not (Parker, 2004).

What no one wanted to deal with is that government corruption and lack of good governance, not trade were behind the uncontrolled poaching of elephant, something that CITES on its own could not resolve (Bonner, 1993). In many cases, this was still the case in 2002.

Meanwhile in Southern Africa, elephant numbers were on the increase (Leakey & Lewin, 1995).

10.3 CITES

The Convention for the Preservation of Animals, Birds and Fish in Africa of 1900 was the basis for most of the colonial wildlife legislation in Africa and a forerunner of "The Convention on International Trade in Endangered Species (CITES)" of 1973. CITES brings states together to control the trade that may endanger species of animals and plants. Animals covered by CITES are classified into three categories (CITES, 2005a):

- **Appendix I.** Species that are threatened with extinction, which may be affected by trade (endangered by trade). They cannot be traded, with the

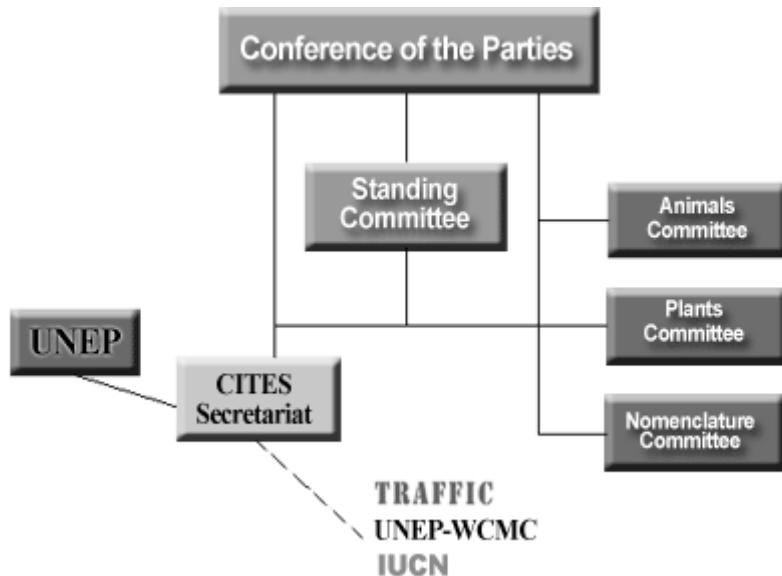

exception of hunting trophies under permit, hunting being considered non-commercial trade, which requires export documentation.

- **Appendix II.** Species which although not necessarily now threatened with extinction may become so unless trade in specimens of these species is subject to strict regulation in order to avoid utilization incompatible with their survival.
- **Appendix III.** All species which any party identifies as being subject to regulation within its jurisdiction for the purpose of preventing or restricting exploitation and as needing the cooperation of other parties in the control of trade. Any country can request a listing of its own species that allows relatively free-trade.

Classifications of species by “appendix” can be found in various databases linked to CITES (CITES, 2005b; UNEP-WCMC, 2005a). The classification of species is supposed to be based on sound science, but more often than not, it is based on eco-politics. The CITES conferences are intense media events with NGOs on both sides of the fence, sustainable use as opposed to animal rights, lobbying to assert their ideologies and impose their organizational interests on the parties. Many of the parties (member countries) come with pre-determined positions. According to Parker (2004), CITES failed to recognize that the 1933 Brussels Convention on African Conservation had already introduced hunting/trade categories: Class A of species that could not be hunted or traded and Class B for species that could only be hunted and traded on permits. Yet, animals continued declining.

CITES is organized as follows (Figure 10.1).

1954

Source: CITES (2006) with permission, CITES.

Figure 10.1: Organization of CITES

The CITES secretariat is administered by the United Nations Environmental Program (UNEP) and is based in Geneva, Switzerland. It plays a coordinating and advisory role to the signatory states (countries) to the convention called “parties” collectively referred to as the “Conference of Parties (COP)”, who meet every two years to determine the classification of trade in species globally.

“The Standing Committee provides policy guidance to the Secretariat concerning the implementation of the Convention and oversees the management of the Secretariat's budget. Beyond these key roles, it coordinates and oversees, where required, the work of other committees and working groups; carries out tasks given to it by the Conference of the Parties; and drafts resolutions for consideration by the Conference of the Parties” (CITES, 2005c).

The Animal and Plants Committees of experts were established

“to fill gaps in biological and other specialized knowledge regarding species of animals and plants that are (or might become) subject to CITES trade controls. Their role is to provide technical support to decision-making about these species” (CITES, 2005d).

The Nomenclature Committee provides advice on scientific names. The United Nations Environmental Program's World Conservation Monitoring Center (UNEP-WCMC), on behalf of the CITES secretariat, manages the CITES Trade Database that monitors the trade in CITES-listed wildlife and plants, providing the secretariat with annual reports. Additionally, annual reports from the scientific authority of each country (party) are provided to the secretariat and are used by the scientific authority of each of the member countries to detect problem areas and take remedial steps (DEAT, 2004a). Affiliated with the International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU) and the Worldwide Fund For Nature (WWF), a joint wildlife trade-monitoring program, the Trade Records Analysis of Flora and Fauna in International Commerce (TRAFFIC), with offices in about 20 countries. TRAFFIC has a memorandum of understanding to build capacity at regional and sub-regional levels to implement and enforce CITES (CITES-TRAFFIC, 1999)

At national levels, each signatory country/member state “party” has a CITES management authority and a CITES scientific authority, normally within a ministry that deals with overall conservation issues. For instance in South Africa, they are housed within the Department of Environmental Affairs and Tourism. In the USA, they are housed within the U.S. Fish and Wildlife Service (USFWS). First, the scientific authority determines if the science behind the recommended trade for a given species is sound, that is “non-detrimental” to the species. This implies that the exportation or importation of a species from a given country will “not impact negatively on the survival of that species in the wild” (CITES, 2005a). A “non-detrimental finding” is necessary before the exportation or importation of a species.

Once the scientific authority issues a “non-detrimental finding”, the management authority authorizes

“the export of a specimen of a species included in Appendix I or II, the export of a specimen of a species included in Appendix III from the State that included the species therein, or the import of a specimen of a species included in Appendix I” (CITES, 2005a).

TRAFFIC believes that the illegal trade in wildlife is second in value only to drugs, with an estimated value of US\$ 20-25 billion/year (Duffy, 2000). In theory, the question should not be how to stop the trade, but how to control it so that the harvest of wild resources is both sustainable and makes an important contribution to the economies of developing countries. However, Western biases prevent this from happening. Duffy (2000) feels that pro-trade parties have been relatively isolated and compromised at CITES.

10.3.1 CITES a Western Control Mechanism over Africa’s Natural Resources and Development

An NGO (Non-Governmental Organization) technically qualified in protection, conservation, or management of wild fauna and flora may apply for observer status. Observers at a COP may attend all plenary and committee sessions, comment in the sessions, but are not permitted to vote on proposals (USFWS, 2003). Their main influence on CITES decisions is through lobbying.

CITES has become a “tool” for Western governments and NGOs, especially the animal rights movement such as the Humane Society of the United States (HSUS),³⁰⁶ Environmental Investigation Agency (EIA),³⁰⁷ International Fund for Animal Welfare (IFAW)³⁰⁸, People for the Ethical Treatment of Animals (PETA)³⁰⁹, to control how Africa and the developing world use their wildlife. It

³⁰⁹ People For The Ethical Treatment of Animals, 501 Front Street, Norfolk, Virginia 235210, Tel: 757-622-PETA, <http://www.peta.org/>

assumes that regulations controlling trade can help prevent species from becoming extinct. In the case of the animal rights movement, the hope is to use CITES to stop all trade in wildlife, as philosophically they see this as immoral. Of course, they have little or no understanding of the impacts on the ground to wildlife when it has no value.

CITES largely ignores socio-cultural and economic constraints (Duffy, 2000), which in the third world may be more crucial to the survival of wildlife than bureaucratic sanctions. Lancaster University political scientist, Rosaleen Duffy (2000), believes that CITES has evolved from a regulatory regime to control trade to a prohibition regime. She believes that industrialized states (the West) and the East African States (whose decision-makers have been bought off by Western governments and NGOs, in particular Kenya and Uganda) favor preservationist methods and thus trade bans, while much of Southern Africa favors "sustainable use" as a conservation policy, believing that unless wildlife has value, its habitat will be replaced by other land uses. She believes that in the case of most international agreements, norms based on Western political ideologies dominate, such as the "precautionary principle" (see Chapter 9, Section 9.2.1, Precautionary Principle; Studying Wildlife to Extinction), and are often reinforced by the Western donors and NGOs with threats of foreign aid cuts and tourism boycotts if African/other countries refuse to comply. Countries like Kenya and Uganda end up having "donor-dependent conservation policies" (Duffy, 2000) that are a disincentive to good conservation on the ground by landholders who are forced out of conservation into other land uses, with wildlife having little or no value.

10.3.2 CITES Fails to Serve Africa

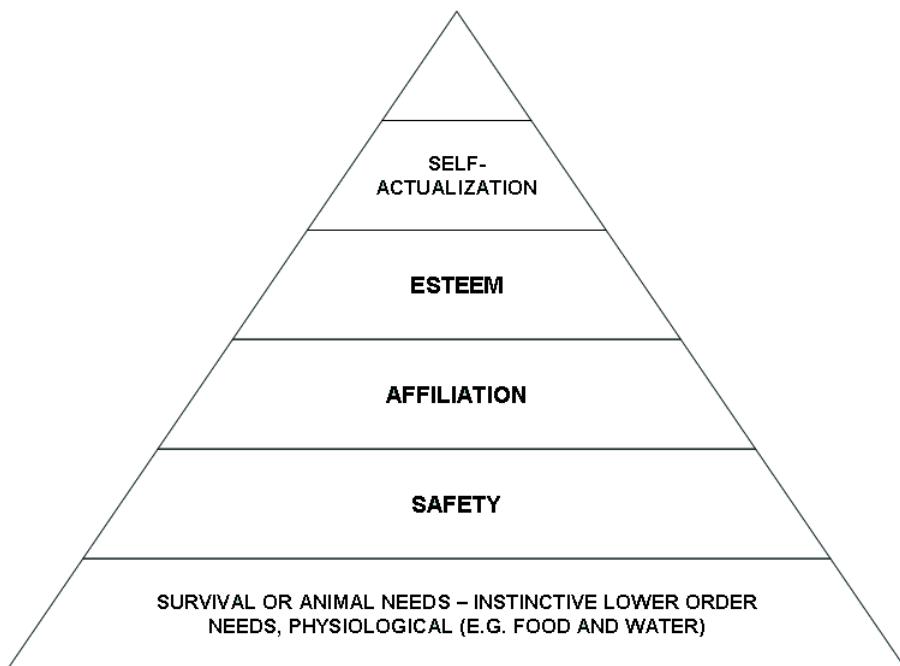

This form of neo-colonialism, which subverts the sovereignty, independence and right to economic development of emerging democracies, assumes that

regulations controlling trade can help prevent species from becoming extinct. A study by Roe, Mulliken, Milledge, Mremi, Mosha and Grieg-Gran (2002 *In: LWAG/DFID, 2002*) indicates that actions by CITES have often reduced income to rural communities without any obvious conservation benefits. They recommend that the “CITES community” be sensitized to the issue of rural livelihoods linked to the trade in endangered species and the implications on these livelihoods by their actions.

CITES ignores many of the real current causes of elephant/wildlife depletion which cannot be addressed through trade control, but must be dealt with on the ground and are integrally linked: 1) poverty, 2) failed centralized management systems, 3) inappropriate governance, 4) corruption at all levels of society, 5) lack of perceived control by rural communities over access to “their” wildlife (e.g., land and resource tenure), 6) alienation by rural communities towards parks and protected areas, which they perceive as having been confiscated from their ancestors 7) inadequate benefits (economic and cultural) to rural communities from elephant and other wildlife, 8) human and livestock populations that have increased an up to 6.5 times during the 20th century (see Chapter 5, Section 5.9, OVER-POPULATION, SOIL DEGRADATION AND DECLINING AGRICULTURAL PRODUCTIVITY) displacing wildlife and leading to, 9) land hunger and resulting habitat loss, 10) failure to urbanize and industrialize at a rate that can take significant pressure off rural areas and their natural resources by offering alternative lifestyles and 11) the illegal bushmeat trade, which could be sustainably managed if legalized, to fill the demand of rapidly growing urban populations in Sub-Saharan Africa.

Thomson (2003) considers the above “proximate causes”. Although the authors whole heartedly agree with his premise, they believe the definition of ultimate/proximate used by Thomson should be reversed, “ultimate” being

poverty, etc. and “proximate” being illegal trade and the black market (See Diamond’s use of these terms, Chapter 13, Section 13.8.6.7, Ultimate and proximate causes of Rwanda genocide). CITES deals only with “proximate causes”, the illegal trade and the black market, which would become irrelevant if the above ultimate causes were addressed. Without addressing these ultimate causes, the proximate causes for the illegal trade in ivory, horn and bushmeat will never disappear. Thomson (2003) believes that the majority of rural Africans, due to the population explosion in the 20th century, are at or near the lowest level of Maslow’s hierarchy of human needs (Figure 10.2), “survival”, and thus are prepared to do anything in order to survive. This survival mode can also be linked to Western policies towards Sub-Saharan Africa, its resources and economies (see Chapters 11-13).

Source: Redrawn from Thomson (2003), with permission, Thomson.

Figure 10.2: Maslow's hierarchy of human needs

Thus, because of these proximate causes, CITES has little impact on what is happening on the ground and unless they are dealt with, both wildlife and their critical habitat are threatened by a wave of poverty already closing in and ready to

1960

invade Sub-Saharan Africa's parks and reserves in the 21st century in search of Sub-Saharan Africa's last uninhabited lands, even if they are marginal for agriculture. One might ask,

"Is what we are seeing in Zimbabwe purely political, or is a large part behavioral: people cooped up in over-crowded communal areas that can no longer provide them with sustainable livelihoods, desperately trying to survive, seeing no value in wildlife, other than as a short-term resource or having been alienated from wildlife as a result of colonialism, invading 'uninhabited parks and conservancies' and ridding the area of wildlife in favor of agriculture and livestock, which they know will allow them to feed their families?" (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife and Chapter 11, Section 11.10.6, Eco-Colonialism - Conservation Driven by Researchers as Opposed to Wildlife/Natural Resource Managers).

Unless there are major changes both within Sub-Saharan African countries and between Sub-Saharan Africa and the West, is Zimbabwe where the rest of Sub-Saharan Africa is heading regardless of the politics? Certainly CITES as a conservation tool does not help the matter by tending to take away the legal value of wildlife!

10.3.2.1 Elephant poaching Mali

"Mali's elephant massacre is the result of slaughter perpetrated in the 1970s by northern Muslims against southern animists and the resulting weakened government. Armed Muslim parties shot all the opposition they could find. In the process, they shot all the wild animals to prevent their enemies from finding game for sustenance. So in addition to the death of one million people, we must add the destruction of 2,000 elephants not to mention those living in neighboring countries in the Central African Republic and Zaire. These killings were done with AK-47's. For every animal confirmed dead, one wonders how many other were wounded and died in the jungles depths...Poachers operated in gangs of 80 to 100 organized Mali and Libyan men, mainly reckless adventurers. The bosses were Libyans. They were sometimes able to penetrate 150 to 200 mi (389-518 km) into Mali" (Tré-Hardy, 1997).

The 1989 CITES elephant ban was supposed to stop this type of activity. The fact is that for the reasons stated above, CITES will not solve Sub-Saharan Africa's conservation problems and in many instances exacerbates them.

10.3.2.2 CITES and the ESA will not save wildlife in RCA's savanna areas. Wildlife in a crisis; the safari industry cries out but no one listens

Like Cameroon, the Central African Republic (CAR/RCA) has both savanna and forest habitat. Most of Africa's Lord Derby eland population (15,000) lives in the savannas of CAR. The CAR forest area in the southwest, Dzanga-Sangha, is part of the new tri-national park linked to the Nouabalé-Ndoki Park in Congo Brazzaville and the Lake Lobéké National Park in Cameroon. Wildlife in CAR's savanna areas is in a crisis.

Prior to the worldwide 1989 ivory ban, records show that in one year, ivory from 10,000 elephants in the CAR was legally exported. Bokassa's (former President) poachers were organized into a state company and busily killed elephants, all the while acting under the pretext of collecting tusks from already dead elephants. Their friends from Sudan, also free-lance operators, helped in this regard (Tré-Hardy, 1997). Did CITES stop the massacre? No, it did not.

The country was run into the ground by the past Presidents Patassé and Bokassa. Functionaries were paid irregularly. The entire system was very corrupt. Advisors to the president were not advisors placed by the French government. They were what the French call a "basket of crabs" (*panier des crabes*), many not able to return to France without being arrested. They formed a sort of unregulated crime syndicate, which gave a cut of all profits to the president. It is unclear as to whether this has changed under the new leadership in 2003 (SCI Africa Office,

2001a).

There was much controversy over the illegal shipment of Lord Derby eland (20) and western roan (33) out of the CAR in 2000, without proper documentation or authorization of the Game Department by Ricardo Ghiazza, a South African (Italian) game capturer. They were shipped to Togo where they were given legal export documentation with Togo as the country of origin, even though there are no eland left there and only very few roan. President Étienne Gnassingbé Eyadema of Togo³¹⁰ and ex-President Ange-Félix Patassé of RCA are brothers-in-law and this is where Patassé currently lives in exile. The Lord Derby eland were then given temporary transit permits into South Africa and appear destined for an Asian market, though a foot and mouth outbreak in South Africa slowed up this process. Ghiazza's modus operandi was to bypass the line management agency (Eaux et Fôrets/Game Department) and obtain permission from the Office of the President. Walter Betschel, another scam artist, who moves between Austria and Africa, bypassed the line management agency, confiscating long-time hunting operators' concessions by going right to the president. This created incredible instability in the safari industry and put unscrupulous individuals like Betschel in control of hunting concessions that risked to be shot out for short-term gain (SCI Africa Office, 2001a).

Lord Derby eland is a flagship species for the CAR and Cameroon and is the basis of the hunting industry in the savanna lands of these countries. There are certainly less Lord Derby eland (15,000) than elephant and leopard in Africa. The Lord Derby eland is not on the CITES list and only the Western race in Senegal is endangered on the USA Endangered Species list. If it was to be placed on CITES, much of the current flexibility to manage this species and to derive direct benefits would be lost for both the CAR and Cameroon. It would not save the

³¹⁰ Deceased in 2005. Presidency taken over by his son in disputed election.

eland, as international trade is not the issue, but rather the localized commercial bushmeat trade, poor governance, anarchy in the surrounding countries and the loss of these areas as common property by rural communities (SCI Africa Office, 2001a).

What is laughable is that this information, provided by the CAR safari industry and the Game Department³¹¹, about the illegal shipment of the Lord Derby eland was passed on to both the U.S. Fish and Wildlife Service (USFWS) and the Endangered Species Protection Unit of The South African Police (now defunct) by the principal author while managing the Africa Office of Safari Club International (SCI)³¹². Nothing ever happened to Ghiazza. To have even brought them into South Africa, he must have paid someone off, since any wildlife official worth his/her salt should have known that their origin could not have been from Togo.

Uncontrolled poaching in CAR from Chad and Sudan for meat and ivory continues to be a problem into the 21st century. The safari operators cry out but no one listens! One of the last really good areas with healthy populations of unique savanna species (Lord Derby eland, western roan, sing-sing waterbuck, *buffle du savanne*, *kob du buffon*, bubale, etc.) is in the north central part of the CAR, part of the *Program de Developpement de la Region Nord* (PDRN project area), funded by the European Union (EU). About 500-700 Sudanese poachers overran it in 2001. About 300 elephant alone were slaughtered within a few kilometers of the main PDRN Camp at Sangba, with substantial amounts of additional but un-quantified elephant and other animals slaughtered for ivory and

1964

meat. As in Cameroon, the poaching of wildlife for meat and ivory is the biggest threat to the future of hunting in CAR (SCI Africa Office, 2001a).

In 2005, Nigel Hunter, director of the UN organization, Monitoring the Illegal Killing of Elephants and wildlife trade expert Esmond Martin estimated that 6,000-10,000 elephants are killed annually for ivory from the Central African Republic, DRC and Chad. The trafficking of this ivory is through Sudan by the Sudanese army with China as the final destination (Majtenyi, 2005). In 2007, Sudanese poachers killed a French professional hunter. Some say it was a deliberate ambush in retaliation for a “shoot-to-kill” anti-poaching effort headed by a Russian ex-special forces officer, while others suggest the poachers were surprised by the vehicle, mistaking it for an anti-poaching squad (Causey, 2007).

CITES fails miserably here. These poachers have never heard of CITES and could care less about trade bans, sanctions and whatever other diplomatic endeavor might take place between governments. They live outside of Western governance. There appears to be no political will on behalf of government to stop such actions. There has been some talk of getting benefits beyond local government to the villages and then getting them to discuss the problem with their relatives on the other side of the border. An estimated reduction of wildlife countrywide by long time safari operator Charles Henri Mortera (*pers. comm. In:* DeGeorges, 2001) over the last 15 years mostly from both local and commercial poaching is contained in Table 10.2. Long-time professional hunter Thierry Fecomme (2001) reinforced these concerns.

1965

Most of the country is poached out with the last good game areas in the central north side of the country including:

- Aouk, D'Jangara, Chad border, savanna area;
- Bamingue, PDRN area, savanna area; and
- Dzanga-Sangha, forest area in southwest linked to the tri-national park.

Table 10.2: Decline of key mega-fauna from poaching Central African Republic (CAR/RCA)

Species	% Reduction (1)	Cause of Reduction (1)	Reduction (2)	Cause (2)
Kob De Buffon <i>Kobus kob kob</i>	-90	Open Floodplains easy to kill by poachers.	> 5,350, Total population of 135,000 in mid-1980s reduced by 90% by 1990s.	Concentration open floodplains, easy for poachers.
Kob Defassa "Sing-sing" Waterbuck <i>Kobus defassa unctuosus</i>	-90	Near water easy to kill by poachers.	> 1,340, Wide-spread reduction, largest population Manovo-Gounda-St. Floris and Bamingui-Bangoran National Parks where 40% reduction in numbers since mid-1980s.	Uncontrolled meat hunting.
Buffalo <i>Syncerus caffer brachyceros</i>	-60-70	Poaching	> 19,000 Eliminated from significant parts of former range.	Poaching
Western Roan (Koba) <i>Hippotragus equinus koba</i>	-50	Poaching	>2,500	Good numbers in Bamingui-Bangoran National Parks. Numbers declining elsewhere from uncontrolled meat hunting from Sudan and Chad.

Table 10.2 (Cont.): Decline of key mega-fauna from poaching Central African Republic (CAR/RCA)

Species	% Reduction (1)	Cause of Reduction (1)	Reduction (2)	Cause (2)
Lewl el Hartebeest (Bubale) <i>Alcelaphus buselaphus lelwel</i> Note: Western Hartebeest (<i>Alcelaphus buselaphus major</i>) extinct for some time from western CAR (2)	-50	Poaching	>8,000. Total population in 1980s 100,000 Main surviving population in Manovo-Gounda-St. Floris and Bamingui-Bangoran National Parks but even here >70% decrease from 1985-1995.	Decline steeply from uncontrolled meat hunting by Sudan/Chad poachers.
Lord Derby Eland <i>Taurotragus derbianus gigas</i>	-30-40	Poaching	> 12,500 out of total for all of Sub-Saharan Africa population of >14,720.	Mobility, shyness and minimum time at water makes them elusive for poachers. Sudanese poaching beginning to be problem.
Lion	-90	Poaching	NA	NA

(1) Mortera (*pers. comm.*) and (2) East (1998)
Table prepared by principal author

Other sources of poaching include:

- **Artisanal diamond prospectors and poaching.** Found in the PDRN area between Quande Dele, Ndele and Yalanga, not in Aouk. Also, found in the southwest and on the border of the new tri-national park area; and
- **Hutu rebel poachers from DRC.** Said to be a big problem.

Chardonnet (2002) attributes the reduction in lion populations in northern CAR to the heavy loss of prey (*kob du buffon*, bohor reedbuck, defassa sing-sing waterbuck) populations due to severe poaching pressure and the

“systematic shooting of lions by nomadic cattle herders entering Protected Areas during the dry season”.

CITES fails in Africa in many ways, especially where anarchy and corruption prevail. Other safari operators such as Bambi (Brooke Chilvers) and Rudy Lubin (*pers. comm.*) and Andre Roux (*pers. comm.*) cry out for the international conservation and hunting community to help, but no one listens and CITES through trade controls cannot stop the devastation on the ground.

10.3.2.3 Politics of despair

Poor national economic policies and performance nullify the great potential of parks and protected areas as important economic generators and reservoirs of biodiversity, since the lack of growth in job opportunities in urban centers or even the contraction of jobs, in trying to survive, can force people back into the rural areas that can no longer support them, exacerbating unsustainable agriculture and other forms of resource mining as a strategy of last resort (de la Harpe, Fernhead, Hughes, Davies, Spenceley, Barnes, Cooper & Child, 2004 *In:* Child, 2004). Over much of Sub-Saharan Africa, because economies are not developing and alternative livelihoods are few and far between, Community-Based Natural Resources Management (CBNRM) programs with their meager benefits and hope for a better future act as a magnet, sometimes placing added pressure on the natural resource base that CBNRM is trying to conserve. In other cases, although there is a tendency for people to leave rural areas for the cities, when they arrive, due to a lack of appropriate urbanization and industrialization and thus few formal sector job opportunities, along with inadequate education that would allow Africans to fit into a global economy, there is believed to be an increasing reverse

migration, which is significant, even if it is small. These returnees do whatever it takes to survive by means of poaching, charcoal making, small farming, grazing and fishing – even if it means degrading the natural resource base. It is believed that IMF/World Bank structural adjustment policies (SAPs) have aggravated this situation (see Chapter 12). Two fine examples of the “politics of despair” are provided in Chapter 9, Sections 9.7.8.1, Politics of despair, Zambia and Section 9.7.8.2, “Politics of despair”, Southern Maasailand “Tarangire Ecosystem”.

CITES, how are you helping? If anything, CITES exacerbates the problem by taking away the value of wildlife and other natural products and forcing over-harvesting to make up for lower prices paid by CITES “created” black markets. By making something illegal, CITES creates an adversarial rather than collaborative relationship at a local level between nature conservation officials and rural resource users. It forces game officials to enforce the law, as they are but “conservation soldiers/policemen”, implementing what the politicians have enacted, and it forces local resource users to harvest clandestinely and/or to opt out for other land uses as in Southern Maasailand and much of Kenya (Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small farmers, Amboseli and Maasai Mara, Kenya.) It creates a lose-lose situation: lower prices for wildlife/nature products for rural people and the inability to manage these resources as they are driven into clandestine black markets discussed in some detail below, where 95% are harvested illegally. The net result is increasing poverty and increasing resource degradation. Granted, this is not just because of CITES, but also because of antiquated government policies that fail to return the resources to rural communities. CITES is the “icing on the cake”, so that even if they had control over their resources, valorization would be that much more difficult to achieve.

CITES thus becomes a cause for decline in wildlife and its habitat by imposing disincentives as opposed to incentives on rural Africans who must bear the burden of living among wild animals. It should be realized that other than for rhino and maybe elephant, habitat loss, not poaching, is the key factor affecting wildlife in Sub-Saharan Africa.

10.3.3 CITES, Drives Ivory Market Underground

In fact, in many instances, by taking away the legal trade value of elephant or other wildlife from Africa and Africans, the wildlife's demise will accelerate. Limited or no trade creates unregulated "black markets" (Duffy, 2000; Thomson, 2003) no different from the "prohibition" of alcohol in the 1920s in America. Parker (2004) goes into some detail on the development of black markets for rhino horn and elephant ivory. The "speakeasies" are Asian countries and the consumers are its citizens. Poaching is beginning to increase in countries like Tanzania (Mantheakis, *pers comm.*) and Cameroon as new parallel markets open to an unregulated trade:

- **Tanzania.** The reduction in the Selous Game Reserve (SGR) budget in 2005/06 [see Chapter 9, Section 9.5.7, Selous Conservation Program (SCP), Tanzania] has been accompanied

"by a steep increase in elephant poaching, which had been so minimal up to 2004 that some of our conservationist friends in Nairobi wrongly suspected that we had forged the figures. Again, as in the 1980s, government vehicles are involved in transporting the tusks of illegal killed elephants, as arrests and confiscations by the police have proved" (Baldus, 2005 *In:* Baldus, 2005).

1970

The World Bank (2005) reports that politically connected middlemen are the real beneficiaries, paying little to the porters that take all the risks. Tanga is considered the main port for these illegal shipments, with consignments under police escort until they are safely out to sea.

“Over a five year period, 3,704 kg of ivory in transit were intercepted and more than 700 guns impounded at various exit points from Tanzania. Valued at the price that a professional hunter pays for an elephant (US\$ 5,000) the government revenue loss through a single illegal consignment of ivory is US\$ 200 million (error – correctly US\$ 200,000) for 40 elephants killed in sport hunting” (World Bank, 2005).

In late 2005/early 2006 over a four-month period, three lots of 84, 94 and 27 tusks, amounting to about 103 elephants, have been impounded from around the Selous Game Reserve (SGR), with 80% of these tusks coming from the Open Areas of Liwale and Kilwa in the southern and eastern part of the Selous. District authorities are involved (Kibonde, 2006) as well as the military, though those involved at the top of the ivory trafficking pyramid have yet to be identified (Kibonde, *pers. comm.*). The problem is that with a failed wildlife management area (WMA) process,

“the absence of community benefits from wildlife management provides poor rural households with little incentive for conservation” (World Bank, 2005) (see Chapter 9, Section 9.6.3.6, SCP, Tanzania).

- **Illegal Ivory in Cameroon, 2005.** Five poachers were caught with about 100 elephant tusks, leopard and chimpanzee parts using a military truck in September 2005. The Central African region is the principal source of illegal ivory in trade today, both within Africa and internationally, with the forests of southern Cameroon and northern Gabon being among the

last refuges of the threatened Central African elephant (ANON, 2005) (for further discussion on poaching by the Cameroonian military see Section 10.7.2.1, “Enhancement” under the ESA linked to CITES, condemning more wildlife to die? Enhancement Under the ESA as an Impediment to Conservation of Cameroon’s Elephant).

- **Illegal Ivory From Cameroon, 2000.** Ivory poaching is a big problem within the tri-national park of the Lake Lobéké/Chute de Niki/Boumba-Bek National Parks in the southeast forested area of Cameroon, the Nouabalé-Ndoki National Park in the Congo and the Dzanga-Sangha National Park in the CAR. This area has an estimated 70,000 elephants serving as the focus for poaching. In the year 2000, elephant ivory from the tri-national area’s forests was seized by Taiwan customs officials. The vessel originated from Douala, which seems to be the major source of illegal exports. There were 248 tusks, amounting to 2.5 tons and valued at CFA 3.5 billion (US\$ 7 million) (Koulagna, *pers. comm.* In: SCI Africa Office, 2000).
- **Illegal Ivory From Cameroon, 1998.** In 1998, French customs briefly detained a North Korean diplomat at a Paris airport after finding nearly 600 kg (1,300 lbs) of ivory in his luggage. Officials were intrigued that the man, traveling from Cameroon to China, was traveling with 20 suitcases (Djoh a N’Diang, *pers. comm.* In: SCI Africa Office, 1998; SCI Africa Office, 1999).

This is spurred on by a rural populace who do not know or care about CITES and who in trying to survive will take any opportunity they can to generate income, even without the added value of the international market (value goes to the middleman). Thus, elephants and other wildlife become a short-term resource,

whose future CITES cannot control; this is in the hands of the people living with the elephants – rural Africans! The above quantification is likely the “tip of the iceberg” with regard to elephant poaching. For every poacher caught, there are likely 100s that get away, especially if the military or high-level government officials provide cover and protection (Tomlinson, 2007).

10.3.4 CITES Cannot Stop the Bushmeat Trade

The 11th CITES Conference of Parties (COP) held in May 2000 in Nairobi, Kenya, acknowledged the importance and seriousness of the illegal bushmeat trade. The bushmeat trade is another area which has become important to CITES, but which regulations are unlikely to control. At the 11th CITES Conference of Parties, a Bushmeat Working Group (BWG), comprising six Central and West African range states was established as a result of concerns that many Appendixes I and II species are being eaten into extinction and to begin harmonizing legislation and coordination with regard to the bushmeat trade. Its headquarters are based in Yaoundé, Cameroon. Peterson (2003) believes that the three major causes of the bushmeat crisis are: 1) modern lethal means of hunting techniques, 2) modern population growth and 3) industrialized logging (see Chapter 11, Section 11.11.6, Eco-Genocide in Southeastern Cameroon, the Forest People and the Dobi Dobi, More Parks and Protected Areas). A largely USA-funded Bushmeat Crisis Task Force (BCTF) formed in 1999 is a consortium of conservation organizations and scientists dedicated to the conservation of wildlife populations threatened by the bushmeat trade. It is based in Washington, D.C., USA. BCTF coordinates with the BWG with a website and fact sheets to educate the public about this issue.

1973

Central Africans eat as much meat as many Europeans and North Americans (30-70 kg/person/year), mostly wildlife. The approximately 25-30 million people living in the forests of Central Africa eat approximately 1.2 million metric tons of wildlife each year (Table 10.3) (BCTF, 2000; Wilkie & Carpenter, 1999 *In: LWAG/DFID*, 2002) – the equivalent of almost 4 million cattle (BCTF, 2000). Peterson (2003) puts the consumption of bushmeat at 5 million metric tons/year for 30 million inhabitants living (not total population) in the Congo Basin, equivalent to 20 million cows and steers. Peterson (2003) estimates that the average resident of the Congo Basin eats 47 kg/person/year of bushmeat compared to 30 kg/person/year in northern industrialized cities (e.g., Europe and North America).

Bushmeat constitutes ~80% of all animal-based protein consumed in Central Africa and it represents as much as 50% of daily protein intake for rural and urban families in that part of Sub-Saharan Africa (Figure 10.3).

In the forest region, as the most commonly hunted antelope (*duiker/cephalope*) numbers decline from over-hunting mostly by snaring and habitat degradation, hunters shift to crossbows and poisoned arrows or more expensive shotguns to harvest primates (BCTF, 2003). Although already unsustainable, Peterson (2003) predicts the demand for bushmeat in the Congo Basin could be 10 million metric tons by 2025 and 20 million tons by 2050. Contamination of hunters when butchering primates is now believed to have been the major reason for HIV/AIDS developing in humans (see Chapter 5, Section 5.8.1, Linking HIV/AIDS to the Bushmeat Trade).

1974

Table 10.3: Estimates of bushmeat consumption in Equatorial Africa

Country	Forested Area (km ²)	Population In Forested Area	Population In Urban Centers Consuming Bushmeat	BUSHMEAT CONSUMED (Tons/Year)	BUSHMEAT Per km ² Of Forest	Bushmeat Consumed Per Person Per Year
Cameroon	155,330	1,424,000	2,214,620	78,077	503	22
CAR	52,236	219,500	539,775	12,976	248	17
DRC	1,190,737	22,127,000	3,782,369	1,067,873	897	41
Equatorial Guinea	17,004	183,000	227,500	9,762	574	24
Gabon	227,500	181,700	581,440	11,380	50	15
Congo Brazzaville	213,400	219,500	1,245,528	16,325	77	11
TOTAL	1,856,207	24,354,700	8,591,232	1,196,393	645	36

Source: Wilkie & Carpenter (1999) *In: LWAG/DFID (2002), Department for International Development (DFID), Great Britain, public domain*

The 2 million km² Congo Basin accounts for 25% of the world's and nearly 75% of Africa's remaining rain forests, containing half the world's wild species: 400 mammal species, 1,086 species of birds, 216 species of reptiles, 400 species of fish, etc. feeding 30 million Africans. Only 20% of the world's rainforests (tropical lowland hardwood forests) remain intact (Peterson, 2003) (see Chapter 5, Section, 5.9.4.1, Current forest cover, Sub-Saharan Africa, Tropical Rain Forests/Dense Humid Forests.

Around the Korup National Park in Southwestern Cameroon, hunting provided 56% of the total village income and was the most important source of income at village and household level with over 80% of the biomass off-take from the national park consisting of terrestrial mammals. In Conkouati, Congo Brazzaville, hunters sold 80% of their catch, resulting in an average household income of 1,250,000 CFA/ US\$ 1,923 (per year?) of which 64% came from fisheries, 16% from agriculture and 20% from hunting (Roe, Mayers, Grieg-Gran, Kothari, Fabricius & Hughes, 2000). Bushmeat is cheaper than domestic meat in the rural areas, but its value increases two to three times by the time it enters major urban centers, often making it more expensive than domestic meat though it remains culturally preferable to the latter (Peterson, 2003). Smoked elephant in Bangui, CAR is valued at US\$ 11.99/kg (US\$ 5.45/pound), "more than any other kind of meat including beef and pork" (Tomlinson, 2007).

In some Central African countries, traditional hunting rights may be recognized within modern law, but hunting for commercial purposes is generally considered illegal unless officially licensed. Modern (*de jure*) laws are often subordinate to customary management regimes due to the lack of capacity of the state to enforce regulations (Roe, *et al.*, 2000) and alienation of rural resource managers against far removed, often corrupt and self-serving centralized management systems, in which case management is guided by customary law or no law at all. Bushmeat

becomes an “Open Access Resource” as centralized management fails and customary laws and management have been weakened and compromised by the state. The widespread practice of selling bushmeat throughout the region demonstrates the general lack of regard for wildlife legislation and the lack of capacity for governments to impose it (Roe, *et al.*, 2000). This is the case even when recognized traditional hunting is rarely traditional, with wire snares replacing vegetative snares and shotguns/high powered rifles replacing bows, crossbows, nets and spears.

In much of West Africa, human population densities are 25-78 persons/km² compared to countries in the Congo Basin of 5-20 persons/km². Wildlife populations have been so depleted by unsustainable hunting (and habitat destruction) in West Africa that bushmeat is no longer the most important source of protein in families’ diets. Rodents have replaced the over-hunted and now scarce antelope and primates as the most commonly eaten wild animals (BCTF, 2002; BCTF, 2003).

Additional estimates of the bushmeat trade in West and Central Africa that could exceed US\$ 1 billion/year in value (BCTF, 2000) include:

- **Bushmeat Cameroon.** 9 tons/day of bushmeat arrive in Cameroon’s capital Yaoundé, 4 tons/day via train and 5 tons/day via logging trucks (MINEF/SCI, 2000). WSPA (2000) and Peterson (2003) estimate that 70-90 tons of bushmeat/month arrive in Yaoundé;
- **Bushmeat Central African Republic.** About 40% of protein in Bangui, the CAR, is from bushmeat. It is estimated that Bangui consumes the annual equivalent of 9,500 tons of fresh bushmeat valued at 8 billion CFA

(US\$ 13.3 million)³¹³ or 1% *Produit Interieur Brut* (BIP - Gross Domestic Product GDP)³¹⁴ and country-wide an equivalent of 48,000 tons of fresh bushmeat valued at 16,500,000,000 CFA (US\$ 27.5 million)/year or 2.5% of the BIP (Canopee, 2000);

- **Bushmeat Gabon.** A minimum of 500 tons/year is sold in the capital Libreville (WSPA, 2000);
- **Bushmeat, Congo Brazzaville.** In Ouesso, the largest town in northern Congo, 5,700 kg/week is consumed (WSPA, 2000; Peterson, 2003), amounting to 0.5 kg/person/week of bushmeat from 39 species in a population of 11,000 people. Gorillas arrive on the average of 1.6/week (Peterson, 2003);
- **Ivory Coast.** The annual yield/catch of bushmeat was estimated at 77 billion CFA (US\$ 152 million)³¹⁵ or 1.4% of the BIP³¹⁶ amounting to 35.5 million game animals (mostly small game such as duiker, civets, warthog, pangolins, porcupines, monkeys and squirrels), but also some large antelopes such as bushbuck (Caspry, 1999). Zeba (1998) provides an estimate that bushmeat contributes US\$ 400 million/year to the Ivorian economy. This amounts to 12% of the total animal protein consumed in

³¹³ CFA 600/US\$ in 2000

³¹⁴ GDP (Gross Domestic Product) is the market value of new goods and services produced by the input factors (capital and labor) located within the geographic boundaries of an economy. Gross National Product (GNP) allocates product according to the *nationality* of the owners of the factors. GDP (Gross Domestic Product) allocates product according to the *location* of the owners of the factors. GDP = GNP - Net Factor Payments (NFP). NFP is the net income paid to domestically located factors by foreign owned factors.

³¹⁵ CFA 507.85/US\$ in 1996

³¹⁶ BIP = *Produit Interieur Brut* = Gross Domestic Product GDP

the Ivory Coast (de Bie, 1990 *In: Lycklama à Nijeholt, de Bie & Geerling, 2001; Kouame, pers. comm.*);³¹⁷

- **Ghana and Parts of Mali.** Bushmeat constitutes a critical source of protein: 40% of the total animal protein consumption takes place in the Ghana savanna zone, 60% in the Ghana forest zone and 20% in the Baoulé region in Mali (de Bie, 1990 *In: Lycklama à Nijeholt, et al., 2001*), particularly for poor people in rural areas (Lycklama à Nijeholt, *et al.*, 2001); and
- **Senegal.** In the 1970s, the population consumed 380,000 tons of bushmeat/year (Peterson, 2003).

Recent studies (TRAFFIC, 2000; Cambell, Nelson & Loikooki. 2001 *In: LWAG/DFID, 2002*) in East and Southern Africa indicate that bushmeat consumption in savanna/rangelands can be as high as in the forests of West and Central Africa, especially in times of economic hardships, drought and famine. For instance, bushmeat was 75% cheaper than domestic meat in Zimbabwe, with similar findings for six of seven countries surveyed in the region.

Barnett (2000 *In: Magome & Fabricius, 2004 In: Fabricius, et al., 2004*) estimates that bushmeat is 50% and 30% cheaper respectively than domestic meat in Zimbabwe and Botswana in rural areas, while in affluent urban centers, bushmeat costs 43% more than beef in Zambia and 157% more than beef in Mozambique. In Botswana, 43% of the households surveyed average 18.2 kg of bushmeat/month in areas where this is the only affordable protein. In the Maputo Province, Mozambique, 50 tons of bushmeat/year is traded. Child and Clayton

³¹⁷ Kouassi Joachim Kouame, Head of Anti-Poaching in Protected Areas, Department of Nature Conservation, Ministry of State/Ministry of Environment, B.P. V178, Abidjan, Cote d'Ivoire, ahounze@yahoo.fr

(2002) estimate that 45,000 inhabitants of the Lupande game management area (GMA) in the Luangwa Valley of Zambia, where poverty and malnutrition are widespread, get some 30% of their nutrition from wild foods (see Chapter 9, Section 9.8.5.2, LIRD).

Barrow, Gichohi and Infield (2000) estimate that the per capita percentage total animal protein comprising bushmeat in East Africa is:

- 5 % in Uganda
- 2.6 % in Kenya
- 1.6 % in Tanzania
- 26.8 % in DRC

In the western Serengeti, Tanzania, more than 33% of the traders rely on bushmeat as their sole source of income (TRAFFIC, 2000 *In: LWAG/DFID*, 2002). In the farming areas of the western Serengeti, even with village game quotas harvested by the Wildlife Department and meat sold cheaply to the community, the trade in bushmeat is estimated to make up 33% of the average farm income (Kauzeni & Kiwasila, 1994 *In: Roe & Jack*, 2001). About 60% of the households regularly sell or consume bushmeat (Enjen Olsen, 1998 *In: Roe & Jack*, 2001). According to some studies for 67% of rural Tanzanians, bushmeat is their major source of protein (DPG, 2005). It is estimated that the illegal bushmeat trade is worth US\$ 50 million/year in Tanzania (World Bank, 2005), which is more valuable than overseas trophy hunting valued at US\$ 27-39 million/year (Baldus & Cauldwell, 2004). Baldus (2002) supports establishing sustainable bushmeat harvesting programs in Tanzania with the idea that “if the consumption of venison, can help to conserve wildlife, we should encourage this instead of banning it”. In the case of the Selous Conservation Program (SCP), participating villages are given bushmeat hunting quotas that are harvested by

1980

village game scouts and the meat is sold inexpensively in the village (see Chapter 9, Section 9.6.3.6, SCP, Tanzania). This appears to be a step in the right direction but does not necessarily address cultural ties to hunting (see Chapter 9, Section 9.7.3, Failure to Integrate Cultural Ties towards Wildlife into CBNRM).

Bushmeat research has tended to be driven by conservation and concern for its impacts on endangered forest species rather than livelihoods. Bushmeat in Sub-Saharan Africa for the most part is consumed within borders of sovereign states over which CITES has no control. A small percentage crosses local borders and almost all bushmeat in Sub-Saharan Africa is traded on the subcontinent, something that cannot easily be controlled by CITES and trade controls (LWAG/DFID, 2002). Furthermore, the majority of bushmeat species are not endangered and thus will be controlled with difficulty by CITES trade regulations (Bowen-Jones & Pendry, 1999 *In:* LWAG/DFID, 2002).

Controlling and/or sustainably managing the bushmeat trade will take on the ground collaboration with local communities, who consume bushmeat and who are involved in the trade of bushmeat to assure that it is sustainably managed. This is beginning to happen on a pilot basis in Ghana through the Ghana Bushmeat Research Project, which favors formalized trade that can be managed over prohibitions, which risk to drive this trade underground (LWAG/DFID, 2002). The new programs of *gestion des terroirs*, which stress sustainable management of wildlife and forests in West Africa, appear to be a way forward. The Wildlife Conservation Society (WCS) in the Congo is said to be working with a German logging company to assure sustainable bushmeat off-take to feed the local workforce. This is another example of on the ground efforts which will be needed (LWAG/DFID, 2002), though some question the validity of this program (Peterson, 2003) [see Chapter 11, Section 11.11.7, Case Study Bongo in the Congo (Brazzaville)]? In Southeastern Cameroon, the Association of

Bushmeat Collectors (*Association des Collecteurs de Viande*) has been functional since about 2005 in an attempt to formalize and begin regulating the trade (see Chapter 11, Section 11.11.6.4, Logging companies and the unsustainable bushmeat trade).

The trade in bushmeat will never be stopped as it is ingrained in the culture of most Africans. This is similar to the urban demand for charcoal in West Africa, where for cultural reasons, people prefer charcoal to other alternatives (e.g., natural gas) for making tea and cooking (Chapter 5, Section 5.9.4.7, Deforestation in savanna environments - Deforestation in Senegal linked to charcoal making, over-population and declining fallow periods and Chapter 9, Sections 9.8.9.2, Communal Natural Forest Management, Guesselbodi, Niger and 9.8.9.3 Community-Based Natural Forest Management, *Gestion des Terroirs*, Burkina Faso). However, these resources (e.g., bushmeat and charcoal production) must be managed and controlled at the local level in collaboration with governments as a sustainable source of income, energy and protein. Barnett (2000 *In:* Magome & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004) states,

“once benefits accrue to land-holders from a resource they own, wildlife play an important sustainable role in community development and, by doing so, ensure its continued survival”.

Certainly, international treaties such as CITES or sanctions on international shipping of logs (see Chapter 11, Section 11.11.6.10, Sustainability of logging in Southeastern Cameroon/the Congo basin, Section 11.11.6.11, Certification for sustainable logging and Section 11.11.6.12, Volume and value of timber from Cameroon/Congo Basin), which could be necessary for other reasons, will not solve these localized problems that are believed to be more of a threat than international trade.

LWAG/DFID (2002) believes that the community managed bushmeat trade has potential but is confronted with the following constraints:

- Different bushmeat management regimes are required for different environments such as primary versus logged forests, farm-fallow areas, savannas, etc.;
- There is a lack of effective community bushmeat management models. Most bushmeat is harvested illegally, empowering hunters and traders while excluding non-members in determining the distribution of benefits;
- Where human population densities are low, there are high transaction costs of intervention (by donors/NGOs) to establish a program;
- There is little social cohesion in peri-urban areas, making intervention along the supply line difficult; and
- Legislative weaknesses and ambiguities over land tenure and user rights and relevant institutions at the national and local level are often weak and/or corrupt.

Alternatives such as substituting domestically raised species for wild species in high rainfall areas have met with limited success due to a lack of food supplies and disease (LWAG/DFID, 2002). A recent analysis by Defo (2005) in Southeastern Cameroon indicates that due primarily to the cost of transport into the area, in addition to cultural ties to bushmeat, domestic and other sources of protein cannot compete with bushmeat economically (Table 10.4). Bushmeat in Southeastern Cameroon sold for between US\$ 0.55-1.46/kg (\approx 547 CFA/US\$ & 650 CFA/Euro) compared to domestic meats that sold for US\$ 2-3.46.

1983

Table 10.4: Comparison of bushmeat prices/Kg to alternative sources of protein, Southeastern Cameroon

TOWN SOUTHEASTERN CAMEROON	Bushmeat Gross Value CFA	Bushmeat CFA/Kg	Bushmeat Euro/Kg	Bushmeat US\$/kg	Domestic Protein CFA/KG	Domestic Protein Euro/KG	Domestic Protein US\$/kg
LIBONGO	Porc-épic ≈ 4kg: 1,500-2,000 CFA	375-500	0.58-0.77	0.68-0.91	Beef: 1,500-1,600 Frozen Fish (<i>Maquereau</i>) 1,300	2.31-2.46 2.00 2.92	2.72-2.91 2.36 3.46
MOULOUDOU	Blue Duiker ≈5kg: 1,500-2,500	300-500	0.46-0.77	0.55-0.91	Beef: 1,500-1,700	2.31-2.62	2.73-3.09
OUFESSO (LAMEDOUM)	Monkey ≈ 5kg: 2,000-2,500	400-500	0.62-0.77	0.73-91	Beef: 1,100	1.69	2

Similarly, Wilcox & Nambu (2007) found in Southeastern Cameroon from 1999-2002 that the most expensive bushmeat, pangolin, selling for US 1.06/kg (\approx CFA 700/US\$ & & 656 CFA/Euro) field dressed, was half the price of the cheapest domestic meat, chicken, selling for US\$ 2/kg butchered. On the other hand bushmeat in the major urban centers can cost more than domestic meat, due to a combination of transport, demand and competitive domestic meat markets (Wilcox & Nambu, 2007).

Game ranching, as in Southern Africa, is capital intensive and requires management and marketing skills not yet available to the majority of the rural poor. Likewise, while the cane rat is a success story in Benin, 600 farmers raising 18,000 rats, Bowen-Jones, Brown and Robinson (2001 *In: LWAG/DFID*, 2002) state that major bushmeat species with the potential for domestication have long been discovered. There is little biological basis for the ability to successfully breed most targeted bushmeat species under captive conditions.

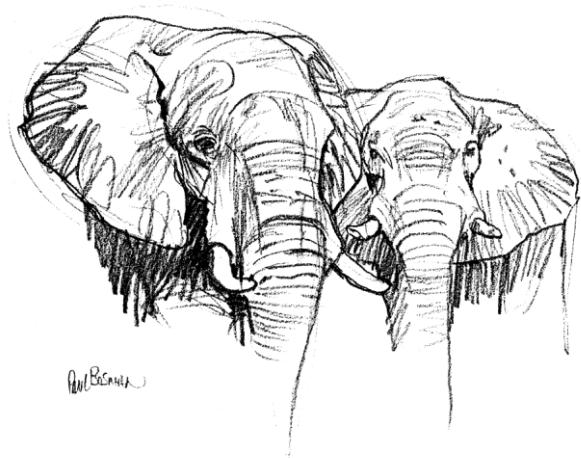

Ultimately, what is wrong with the commercialization of bushmeat? South Africa has among the largest and most lucrative formal bushmeat trade in the world let alone Sub-Saharan Africa. Landowners raise game on their fenced ranches. Game harvested by local meat/biltong hunters along with cropped game sold in butcheries in 2005/2006 was valued at nearly US\$ 449 million/year, over half the total annual US\$ 670,857,142 value of the game industry from sustainable use and more than 4x as valuable as overseas trophy hunting/taxidermy - valued at US\$ 101.5 million/year to South Africa (NAMC, 2006) (see Chapter 5, Section 5.12.7, Attaining Food Security through More Appropriate Land Use Options):

- US\$ 443,000,000/year: Biltong (resident) hunting (66% value of total game industry); and
- US\$ 6,000,000/year: Venison market (1% of total game industry)

1985

As long as it is managed, the bushmeat trade combined with trophy hunting and even eco-tourism is not a problem, harvesting from 12 to 25% of the annual wildlife population.

10.4 THE AFRICAN ELEPHANT

Source: with permission from the artist, Paul Bosman, Wildlife Investment, Inc.,
<http://www.wildlifeart.net/books.html>

“Socio-economic issues are more important than biological issues in determining the survival of the African elephant (*Loxodonta africana*). Elephant and Africa’s predominantly rural population are sympatric and in competition for the same resources. The cost of managing elephant is estimated at not less than US\$ 200 km² or US\$ 800/head/year at sustainable carrying capacity, assuming the level of available expertise. Few African governments can afford to manage elephant or have the expertise, even with the 4% of the region that is nominally protected...African governments cannot afford to compensate indigenous people, among the most disadvantaged groups in the world, for the inequitable costs imposed on them by expecting those with elephant on their land to conserve the species. The net result is that the elephant will survive only if it is the wish of the poor peasant communities struggling to stay alive, and this will be when it is to their economic advantage to do so. Irrespective of any biological criteria, elephant populations will continue to decline, some more slowly than others, unless the species is able to realize its economic advantage so that it can compete favorably for the

1986

limited resources available...The amount of lost revenue by rural communities in living with elephant under prevailing livestock regimes in some 70% of Africa south of the Sahara, where the average rainfall is 750 mm or less, is estimated at US\$ 2,800/elephant/year from lost beef production alone" (Child, 1993).

"Well-meaning preservationists create problems by limiting local people's ability to market certain resources such as elephant products",

a quote from "Evaluating Eden: Exploring the myths and realities of community-based wildlife management" (Roe, *et al.*, 2000).

10.4.1 Threatened Under the ESA

In 1978, the USA classified all African elephants as "threatened" under its own USA Endangered Species Act (ESA) (ESA, 1999; USFWS, 1999), even though they were really only threatened in Kenya and Tanzania, Uganda, Somalia, Sudan, the CAR, Angola, West Africa and Zambia. The "threatened" category falls below the most serious level of "endangered" under the ESA. In theory, for those elephants and/or other species with CITES hunting quotas there should not be a problem coming into the U.S. with proper paper work (e.g., CITES export documentation and veterinary certificate) from the exporting country. However, as is seen below, "enhancement" under the ESA is used to block such entries.

10.4.2 Western Protectionist NGO's Begin Lobbying to Place African Elephant on CITES Appendix I

"...trade in elephant ivory, articulated at international level through meetings of the Convention on International Trade in Endangered Species (CITES) has led to serious conflict between those in Southern Africa who argue for the rights of local communities to utilize elephants in a sustainable way, and Western pressure groups who believe that any trade in elephant ivory will

lead to high levels of poaching and their ultimate extinction" (Roe, *et al.*, 2000).

In the 1980s, the ivory trade was worth US\$ 50-60 million/year to Sub-Saharan Africa. However, there were problems. In the 1980s, the African elephant population was cut in half from 1,300,000 to 600,000 (Duffy, 2000; Thomson, 2003) mainly due to illegal off-takes, often with government complicity, especially in Kenya, Uganda, Tanzania and Zambia, while Southern African elephant populations continued to grow and were well managed (Duffy, 2000) (see Section 10.2, AFRICAN INDEPENDENCE AND POACHING).

The demand for ivory in the 1970s and 80s came primarily from the U.S., Europe and the Far East, especially Hong Kong and Japan, which accounted for 75% of the pre-ban ivory imports for jewelry and personal seals (*hanko*) in Japan and carvings in Hong Kong for re-export to China, Japan, South Korea and Taiwan.

In order to control the illegal export of ivory, CITES created an export quota system where each country set its own quotas. Countries whose tusks were not CITES acceptable, sold them at half the market price through countries like Burundi, Singapore (Duffy, 2000; Parker, 2004) and Dubai (Parker, 2004) that had no indigenous elephants. It is estimated that Burundi was exporting the ivory of 18,000 elephants/year smuggled in from surrounding countries (Rosenblum & Williamson, 1990). Potgieter (1995), in an interview with Ian Parker, and Parker (2004) go into great detail with regard to how Burundi, that was not a party to CITES in 1986, was the largest exporter of ivory in Africa. In 1985 CITES parties decided that no future ivory tusks could be traded without accompanying CITES certificates. CITES parties had 18 months or until the end of 1986 to register existing stockpiles (Potgieter, 1995). In collaboration with CITES, attempts by Parker to register Burundi's "pre-convention" ivory failed as a lever to have Burundi become a party to CITES, and to move this ivory out of the country so

that the stores would be empty. This would make it difficult for new ivory to be illegally trafficked through Burundi from other countries. Parker estimated the 18,000 tusks weighing 90 tons that he found in Burundi to be linked to a US\$ 35 million/year trade. He estimated that over a five year period leading into 1986 that 1,500 ton of ivory averaging 5 kg/tusk had been smuggled into Burundi from neighboring countries, representing over 100,000 elephants. The CITES secretariat panicked when seeing how much ivory was involved and decided not to let the ivory out of Burundi immediately. This is believed to have resulted in illicit ivory increasing in value by 300% and encouraging more poaching. Parker links the smuggling of Burundi ivory off the continent, laundered through Mozambique as legal CITES certified ivory, to the South African intelligence community and the infiltration by these individuals into Operation Lock that was supposed to stop such smuggling (see Chapter 13, Section 13.7.1.1, Legitimization of private military companies/contractors [PMCs] by Western governments and international bodies) (Potgieter, 1995; Parker, 2004). The IMF/World Bank driven liberalization of economies in countries such as Tanzania, Zambia and Zaire resulting in freely convertible currencies eventually ended Burundi's role in ivory trafficking (Parker, 2004).³¹⁸ However, this has

³¹⁸Burundi franc fixed 1 to 1 against Belgium franc and eventually linked to US \$, as well as gold during period in question. By 1970s Tanzania Uganda and Kenya Shillings pegged to US\$ and/or pound sterling, but as the US \$ left the gold standard on August 15, 1971 and currencies fluctuated widely These countries at times stopped all foreign currency transactions, but by late 1975 pegged their currencies to IMF Special Drawing Rights (SDRs), after which their currencies continued to devalue under various relationships. By 1990, Uganda opens first FOREX bureaus, Tanzania following in April 1992. Burundi's currency remained stronger, linked to gold until 1978, not following the devaluation of the U.S. dollar as the other three countries, but by 1983 pegged to the SDR, after which it also suffered devaluation. Neighboring DRC, fluctuated back and forth between being pegged to the Belgian Franc and US\$ during this period, switching to the SDR in 1976 (Schuler, 2007). Parker (2007a) remembering those times says, "I do not have Burundi exchange rates, but can confirm that all currencies were freely convertible. One set of ivory/gold buyers, had so great a demand for dollars that they imported them in parcels directly from Switzerland. I was so incredulous that I wanted to see this for myself, and personally went with them to collect \$250,000 in brown paper parcels with seals off a Sabena flight at Bujumbura. It even crossed my mind that if ever I was to conduct a heist this was the place to do it. Park my own aircraft at the airport, intercept the parcel carriers, take the parcel(s) and just fly away. Thus did I dream"!

done little to end the black market trade in ivory (see Section 10.3.3, CITES, Drives Ivory Market Underground) or to allow large quantities of ivory to be moved through legal CITES loopholes (see Section 10.4.6.4, Zimbabwe). Burundi and Singapore eventually joined CITES, but at the height of their ivory trading, they were not members. Burundi still has about 80 tons of ivory stockpiled that CITES will not allow it to sell (Parker, 2007b).

While the decrease in ivory exports³¹⁹ from Sub-Saharan Africa was often attributed to the ivory quota system, others believed that it was due to declining tusk size from a declining and younger elephant population, resulting in more elephants being killed for less ivory. There was a concern that corrupt officials were moving illegally harvested ivory through the “legal” ivory quota system through a legal loophole. “Carved ivory” was not covered in this quota system. In addition, the illegal trade thrived in parallel. Everyone from African government officials to diplomats was involved in the smuggling of ivory (Duffy, 2000). Parker (2007b) argues that CITES permits have always been required for carved ivory, though it is sold illegally on a large scale around the world. If so, as will be seen below, there are other loopholes, and/or as noted, there is the black market that is difficult to control!

By the late 1980s, Western protectionist NGOs mounted a campaign to upgrade elephant onto CITES Appendix I, which would stop trade in elephant ivory and other products. One of the leaders behind this movement was the African Wildlife Foundation (AWF), an NGO started in America by hunters to train Africans in wildlife management at the time of independence. They helped start the Mweka Wildlife College in Tanzania (official name, College of African Wildlife Management, Mweka) (Bonner, 1993).

³¹⁹ Fell from 868 tons/year from 1979-1985 to 587 tons in 1986 and to 176 tons in 1989.

1990

By 1983, AWF had become a classic Western conservation NGO, of which the main objective was to raise funds for Westerners to undertake “pure” wildlife research in Africa, most of which had no applied management objectives (see Chapter 11 Section 11.10.3, Creation of Powerful Conservation NGOs by Western Donors). AWF was the first to call for a total ban on ivory trading in 1989. In 1988, when AWF launched its “Don’t buy ivory” campaign, its budget was US\$ 2 million/year. After this campaign, its membership doubled and it became a major player in the “wildlife game” (Bonner, 1993).

AWF and most traditional conservation NGOs (e.g., WWF/U.S.,³²⁰ WWF/International³²¹ and Wildlife Conservation International³²²) and their researchers did not believe that a total ban on the ivory trade would stop elephant poaching. Besides, for a number of Sub-Saharan African countries, ivory sales generated a substantial amount of revenue for both conservation and government. For instance, Zimbabwe in the 1980s earned US\$ 2 million annually from legal ivory sales (Bonner, 1993).

However, the membership constituency of many NGOs was not sophisticated enough to understand how revenue from the killing of elephants could save elephants. Most members believed that contributing money to these NGOs was helping to preserve wildlife. These NGOs did not try to explain concepts such as sustainable use, culling, game cropping³²³ and hunting in the African context and why wildlife must serve as an economic and cultural resource for management and poverty alleviation if it is to survive (Bonner, 1993).

³²⁰ WWF-US, Washington, D.C., <http://www.worldwildlife.org/>.

³²¹ WWF International, <http://www.panda.org/>.

³²² Today: Wildlife Conservation Society, New York, USA, linked to New York Zoological Society <http://www.wcs.org/>.

³²³ Cropping is the sustainable harvest of meat, skins and other by-products from a game population for economic purposes. Culling is reduction of a game population as part of a management strategy.

Thus these NGOs, against the opinions of many of their staff researchers, opted to support a ban on the ivory trade as a fund-raising mechanism for themselves (Bonner, 1993; Duffy, 2000), as well as out of fear of membership losses if they came out in support of elephant culling (Bonner, 1993). This has not changed even in the 21st century. In essence, these NGOs joined with the animal rights movement, including the Environmental Investigation Agency (EIA), the Humane Society of the United States (HSUS), Friends of Animals,³²⁴ Defenders of Wildlife,³²⁵ International Fund for Animal Welfare (IFAW), sacrificing their principles for money and abandoning most Africans as well. Only David Western of Kenya and the Wildlife Conservation International/Wildlife Conservation Society (WCS) would seek some accommodation to the Southern African requests (Bonner, 1993) where elephant populations were growing.

Graham Child (1995) equates the use of elephant by Western NGOs for fundraising with a form of “commercial poaching” in which elephants are used for commercial gain with little or no concern for the elephant, or other species. If anything, he believes that Zimbabwe should be reprimanded for having too many elephants, which are destroying the natural habitat and biodiversity of the country. It takes about 4 km² to support one elephant (Martin, 1989; Craig, 1989 both *In:* Child, 1995). This would have required 40-80% of Zimbabwe’s territory by the mid-1990s given their elephant population. These Western NGOs were backing failures in elephant management, such as Kenya, and punishing countries like Zimbabwe, Namibia and Botswana for conservation successes, by taking away the economic incentives for conservation and the much needed revenues for conservation and development that could come from the legal sale of skin and

1992

ivory. Child (1995) goes on to say that the push for the 1989 ban on the commercial sale of elephant products by well-intentioned urban Westerners as a means of saving the elephant was just the opposite of the pragmatic economic approach taken by rural Zimbabweans in achieving the conservation of this charismatic natural resource. This demonstrated their complete misunderstanding for the realities on the ground at the time. Thus conforming to anthropocentric norms such as not killing animals allows charismatic mega-fauna such as elephant, to which we so closely relate, to damage long-term ecological processes (Child, 2004).

Just prior to the trade ban in 1989, ivory was bringing in US\$ 300/kg, while poachers were making maybe US\$ 65/elephant killed, tusks averaging 5 kg each. As opposed to formally integrating rural communities and even rural poachers, “traditional hunters”, into the sustainable management of elephants, the ban continued(s) to drive the black market, rural communities getting a fraction of what they could get from a formal and legal market. From elephant hide alone, Zimbabwe was making US\$ 1.2 million/year, a product that came from regulated government culling, as poachers could not deal with this product deep in the bush (Thomson, 2003).

A major media blitz was run in the West about the slaughter of the “endangered” African elephant. By June 1989, all ivory imports were banned into the USA under the African Elephant Conservation Act (AECA) passed by the U.S. Congress to save the elephant. The Act (AECA) exempted tourist hunting (sport hunting) trophies of elephant where it could be demonstrated that regulated sport hunting contributed to elephant conservation and was not the cause of the decline (Bonner, 1993).

1993

The Southern Africans mounted a campaign to spare their elephants from the CITES Appendix I listing, led by people like John Hanks, David Cumming and Rowan Martin. Tanzania and Kenya took the lead in listing the African elephant on Appendix I of CITES. Tanzania was later shocked to discover that the USA had stopped the import of African elephant hunting trophies, unless proven beneficial, as well as commercial imports of ivory. Kenya, on the other hand, had not had tourist hunting (sport hunting) since 1977, so it had no such legal trade to care about (Bonner, 1993).

10.4.3 U.S. Government Threatens African Countries with Foreign Aid Cuts

In July 1989, 17 African countries met in Gaborone, Botswana, to come up with a unified stance on elephants for CITES. Only five African countries supported the ban, namely Kenya, Tanzania, Ethiopia, Somalia and Zaire. The meeting was dominated by U.S. and European protectionist groups. The U.S. Government subtly threatened both Zimbabwe and Botswana with foreign aid withdrawals if they did not support the ivory ban. They initially refused to accept the Tanzania/Kenya proposals (Bonner 1993). Thomson (2003), who attended the 1989 CITES conference, claims that the U.S. delegation threatened all African countries who would vote against placing elephants on CITES I with foreign aid cuts.

Duffy (2000) explains that northern states threatened cuts in foreign aid for states that supported Zimbabwe, Botswana and Namibia's request for trade in ivory, while only supporting trade if there was a common African policy on ivory trade, but making the achievement of this goal very difficult if not impossible. The French have made similar threats to their former colonies at COPs 10 and 11 (Francophone Africa Delegates to CITES COP 10 and 11, *pers. comm.*).³²⁶

1994

10.4.4 Leakey and Ivory Burning, Good for Kenya but No One Else

A few days after this meeting, Richard Leakey, the new Kenya wildlife service director, held the famed burning of 12 tons of ivory, worth US\$ 3 million (Bonner, 1993; Leakey & Morell, 2002). President Moi lit the fire saying,

“To stop the poacher, the trader must be stopped. And to stop the trader the final buyer must be convinced not to buy ivory. I appeal to people all over the world to stop buying ivory” (Leakey & Morell, 2002).

This was to be the “shot heard round the world”, and was the lid on the casket for the ivory trade. This publicity helped Leakey and the Kenya Wildlife Service (KWS) to become the recipient hub of US\$ 150 – 250 million from the World Bank, USAID, Japan, Germany and Italy, so many joined with Kenya in the mistaken belief that they too could share in the wealth (Bonner, 1993; Leakey & Morell, 2002). Thomson (2003) claims that in a personal conversation he had with Leakey, while debating with him at Wits University, South Africa, in 1992, Leakey claimed that he had been coerced into burning the ivory by the Americans who promised him [Kenya Wildlife Service (KWS)] US\$ 300 million. If correct, this implies that the U.S. government, infiltrated by animal rights groups, was an important role player in the ivory ban, using covert tactics along with threats of foreign aid cuts to orchestrate the African elephant being placed on CITES Appendix I. No one thought to ask the rural poor what they thought or to consider the benefits of the ban to organized crime that takes advantage of this poverty.

At CITES in October 1989, a counter proposal for a split listing, Appendix II for Southern Africa and Appendix I for the rest of Africa, which would allow Southern Africa to commercially trade in ivory, was defeated 70 to 19. At the same time, advocates of an Appendix I listing for all African elephants did not have the two-thirds (67%) vote required for a CITES proposal to be adopted. The

1995

majority of Africans wanted to keep the elephant on Appendix II, which would allow legal commercial trade and were supported by many developing world states (Bonner, 1993).

AWF suggested that all elephant be placed on CITES Appendix I, with the right of a given country to submit to a CITES panel of experts a request to have its elephant population down-listed. This was submitted as a proposal by Somalia and passed 76 to 11 (Bonner, 1993). The countries of Zimbabwe, Botswana, Mozambique, Congo, Gabon, Cameroon and South Africa, who combined have over half the continent's elephant population, voted against this proposal (Bonner, 1993). All African elephants were on CITES I and Sub-Saharan Africa, its people and their natural resources lost again to eco-colonialism. Once again, the fate of Sub-Saharan Africa's resources was being decided by Western states and NGOs imposing their values on the continent. Only this time, the mix included many protectionists and animal rights groups that had recently appeared on the scene (Bonner, 1993).

The fallout from this battle over sustainable use versus preservation resulted in key proponents of sustainable use, such as John Hanks of WWF/International's African Program and Eugene Lapointe, then secretary general of CITES (Thomson, 2003), becoming casualties and losing their positions to preservationists. Countries such as Zimbabwe saw an increase in ivory poaching between 1989 and 1992 (Duffy, 2000) as a black market developed.

10.4.5 Does CITES Help Southern African Elephant Conservation?

Southern Africa (Botswana, Zimbabwe, Namibia and South Africa) had stable and growing populations of elephants to the point that annual culling was required to properly manage habitat and biodiversity. Good conservation and management

1996

had brought these herds back from the devastating slaughter at the turn of the 19th century. Elephant populations in Southern Africa are anything but endangered, with annual increments (growth rates) of from 5-7% resulting in a doubling in numbers every ten to 15 years respectively (Thomson, 2003), in spite of some organized poaching of elephant by governments to fund destabilization campaigns during the liberation wars (e.g., South Africa used poached ivory to support rebel groups such as National Union for the Total Independence of Angola /*União Nacional Para a Independência Total de Angola* (UNITA) in Angola and *Resistência National Moçambicana* (RENAMO) in Mozambique) (Potgieter, 1995; Duffy, 2000; Parker, 2004) (Table 10.5). As many as 100,000 elephants were allegedly killed by UNITA rebel forces for ivory that was transported out by South Africa (Potgieter, 1995).

Although the South African National Parks (SANparks) is custodian to more than 80% of the country's elephant population, the number in private possession is rapidly increasing. Cumming (2005) estimates current elephant populations in Southern Africa, in the above countries plus Mozambique, at 250,000 in 2000. It could grow to 400,000 by 2020 unless numbers are contained. As elephant populations have grown outside of parks and protected areas, their range has decreased, while inside their densities have increased, placing tremendous pressure on the remaining habitat. Due to humans and the increase in their livestock, wildlife today makes up only 10% of the large herbivore biomass in Southern Africa. Once densities exceed 1-2 elephants/km², woodland in low rainfall areas can be reduced to shrubland such as in the savanna woodlands (Cumming, 2005).

Table 10.5: Elephant populations Southern Africa, doubling every 10-15 Years

The fact is that the elephant populations are in need of culling in the Kruger National Park, South Africa, northern Botswana and northwest Zimbabwe in the Hwange National Park area (Thomson, 2003). Thomson is concerned that the

³²⁷ Two-hundred trophy hunted elephant/year bring in about US\$ 2 million/year to rural communities in Zimbabwe and another 127 elephants hunted in park estate land bring in US\$ 837,600/year to the Department of National Parks (Heath, *pers. comm.*). The Zimbabwe National Parks' estate in 2000 was estimated to have a dry season carrying capacity of 30,000 elephants (Machena & Chimuti, *pers. comm.*). The estimated population of 84,000 elephants for all of Zimbabwe was about 45,000 over the dry season carrying capacity (Machena & Chimuti, *pers. comm.*; Marawanyika, 2004). Child (1995) estimates a carrying capacity of only 23,000 elephants in protected areas (parks estate) and a maximum carrying capacity of about 50,000 for the entire country if properly managed (Child, 1995).

³²⁸ Approximately US\$ 900,000 is earned per year by rural communities in Botswana from 60 trophy hunted elephants. Money from elephant generates 53% of total community revenue from hunting (Peake *pers. comm.*). The management objective for northern Botswana is between 46,500 – 63,000 elephant (DWNP Botswana, 1991). Some say that the elephant population needs to be cut in half to protect vegetation, soil and biodiversity and afterwards culled annually in the 1000s (Thomson, *pers. comm.*).

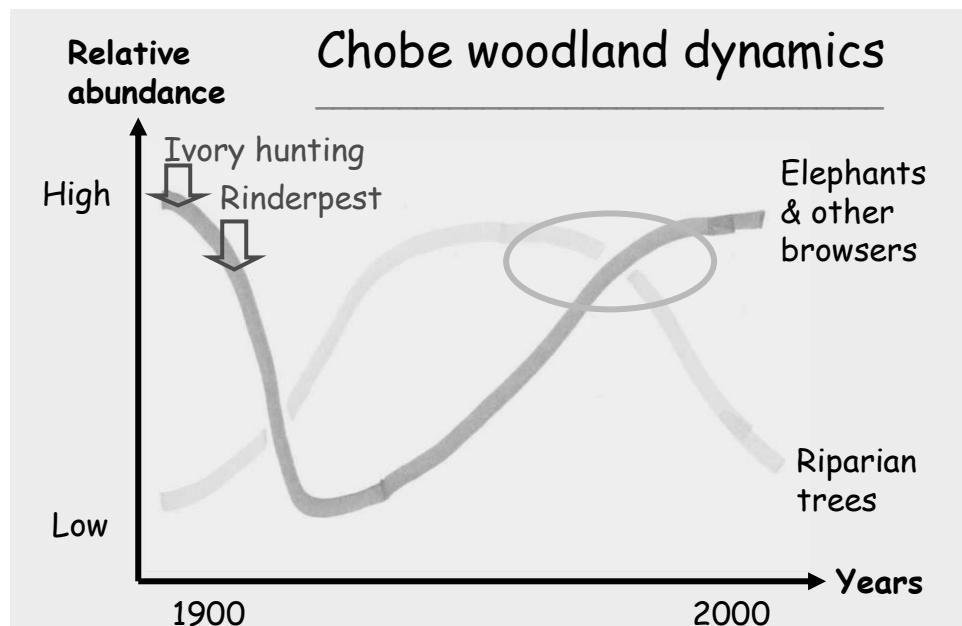

³²⁹ Zambia's elephant population today is said to be stable and increasing primarily due to community-based conservation programs tied to tourist safari hunting (Faddy, *pers. comm.*), though the analysis in Chapter 9 on CBNRM might make one question this to some degree. It appears that trophy elephant hunting reopened in 2005 after being closed for more than 20 years due to stable and likely growing populations of elephant in the Luangwa and Zambezi Valleys (SafariBwana, 2005).

Caprivi/Mahango Game Reserve complex in Namibia, the Chobe Game Reserve/Linyati/Savuti/Moremi/Okavango Delta Complex in Botswana and the Hwange and Gonarezhou National Parks in Zimbabwe have gone well beyond their ecological carrying capacity or habitat sustainability threshold into what is called the “stress period”. This stress period, as a result of “mismanagement” through a lack of elephant culling, is resulting in plant and animal species extinction and a loss of topsoil that make it difficult for vegetation to recover – at least for many generations.

Thomson argues the need for culling in Kruger National Park (KNP) to reduce the current elephant population from 11,000 to 3,000, especially around the Satara area (center of KNP) in order to protect the top tree canopy that is now just 6% (0.78 trees/ha) of what it was in 1960 (13 trees/ha) (Thomson, 2007). Others argue that the northern portion of KNP (e.g., Crook’s Corner) is closing up and that current elephant populations in this area are inadequate to hold back the evolution into forest (see Chapter 6, Section 6.1.4.4, Bush encroachment versus desertification). This argues for making decisions as whether to cull or not to cull on a landscape (particular associations of wildlife, vegetation, soils & topography) by landscape basis, as opposed to a park-wide basis. Possibly elephants around Satara need culling but those in the north can be left to increase as a means of achieving management objectives. Putting aside emotions, ultimately, the achievement of management objectives in a given landscape within a park or reserve by the park/reserve manager should be the driving force as to whether to cull or not.

Johan du Toit (*pers. comm.*) believes that northern Botswana, especially the Chobe area, is an open system with relatively low human populations offering ample room for elephants to disperse. He believes that there is no ecological justification for elephant culling, though there may be economic and/or political

reasons. du Toit (*pers. comm.*) believes that at the beginning of the 20th century, elephant populations were as high as they are today, while riparian woodlands were low. Over-hunting by humans of elephant and other browsers in the 20th century resulted in an increase in riparian woodlands. With strong conservation activities, elephant populations returned (Table 10.5) and riparian woodlands once again declined (Figure 10.4).

Source: Dynamics of acacia woodland from Lewin (1986), *Science*, 234:1071-1073 adapted with permission from American Association for the Advancement of Science (AAAS).

Figure 10.4: Cyclical relationship between elephant and riparian woodlands

Most people think of elephants as feeding on bushes and trees. In reality, they feed on grasses, bushes and trees, the degree being determined by the environment and time of year. Thus, they can compete with both livestock and other grazers (e.g., wildlife). Under grassland conditions, such as prevail at the Murchison Falls and Queen Elizabeth National Parks, Uganda, grass may form 60-90% of the diet year-round. In wooded savannas in Kenya, Uganda, Zambia, Zimbabwe and Tanzania, grass occupies between 40-70% of the diet during the wet season, but only 2-40% during the dry months. Bulls tend to select slightly higher portions of grass than cows. In the tropical lowland forest such as in

2000

Cameroon, Ghana, the Ivory Coast, Gabon, Congo Brazzaville and the DRC, grass is insignificant in the diet of the forest elephant (Owen-Smith, 1992).

During the rains, grasses are eaten, but as the dry season advances, the “environmental bottleneck”, and the ground is stripped of these grasses; trees are the next to go. First riverine and then non-riverine forests are destroyed. As the elephants move further and further from water in search of food, sometimes up to 20-30 km/day, calves are abandoned, starving to death and falling prey to lion and hyena. Eventually, the risk is that there will not be enough food and the elephant population will crash as described in Chapter 3 at Tsavo, Kenya (Thomson, 1997; 2003) (see Chapter 3, Section 3.9.1, Eco-Genocide and the Elephant People).

Thomson (2003) goes on to say that Sub-Saharan Africa’s growing human population is turning much of Africa’s protected areas into hard edges (i.e., surrounded by heavy concentrations of human populations). Once human settlements reach densities of 15.4 people/km² (40/mi.²), elephant cow herds vacate the area permanently and it ceases to be suitable elephant habitat. Hoare and du Toit (1999 *In:* Magome & Fabricius, 2004 *In:* Fabricius, *et al.*, 2004) place this critical density at 15.6 people/km².³³⁰ As these human populations surround a park or protected area, they act as a “living fence”, containing the elephants, other than male crop raiders, within the park. Unable to disperse and with elephant populations doubling every ten to 15 years, unless their numbers are controlled, they can have serious impacts on habitat for themselves, other species and ultimately biodiversity. This is a problem across the subcontinent. Thomson is concerned that a majority of the parks and protected areas, due to elephant over-population and/or poaching, are in a crisis subcontinent-wide. Unfortunately, the

³³⁰ Wildlife management projects cease to be feasible when human densities exceed 20/km² (IUCN/SASUSG, 1997; Murphree, 1997) (Chapter 9, Section 9.7.6.4, CBNRM will not create a “middle class” in rural Africa, CAMPFIRE, Zimbabwe).

2001

Western lobbies (both the animal rights and governments) are against actions such as culling, threatening everything from campaigns against tourism to foreign aid cuts if African countries adopt culling as a management and economic tool. CITES, even when limited trade is allowed, places so many restrictions that it is also a disincentive to invest in sustainable management (Thomson, 2003).

In areas where elephants are compressed and natural systems still exist, Thomson (2003) raises concern over habitat degradation. He gives examples of certain species such as baobab whose life cycle is 5,000 years, riverine ebonies and other large hardwoods of 500 years, with most of Africa's large top tree canopies having a life cycle of more than 100 years. Thomson provides a list of 118 species of important top canopy trees whose genera/species are being or have been selectively eliminated from the above-mentioned Southern African parks due to a failure to control elephant populations. Given human population pressures, once a park/reserve is degraded from over-population of elephant/wildlife through a failure to implement "pro-active management", biodiversity is drastically reduced and the area loses its immediate economic and ecological value. How does anyone think they will keep out the land-hungry impoverished protein-starved masses? In some cases, some poaching – a form of unmanaged cropping – may actually be beneficial to habitat, as some claim for elephant poaching in the Luangwa Valley, Zambia in the 1980s.

Thomson (2003) is also concerned that due to the expansion of human beings outside of Africa's parks and reserves, turning them into "hard edges", the wildlife seed may no longer be available outside these "islands of biodiversity" that can at some point in time recolonize recovered habitat, as must have occurred in the past. Thus, unless habitat degradation from elephant and other species is controlled in Africa's parks and reserves, once Africa's last centers of biodiversity are severely degraded, recovery may become difficult and even these areas could be lost as a source of seed stock.

2002

Similarly, Parker (2004) argues that while commerce has caused some declines in wildlife populations (e.g., whaling and fishing), wildlife has been harvested for centuries and traded without destroying the resource. Like Thomson (2003), Parker (2004) believes that the real problem associated with the decline of African elephants is habitat loss from encroachment by ever growing human populations. This has been true as far back as expanding settlements by Europeans in Kenya, South Africa and the American West that eliminated elephant and other wildlife. This has been exasperated in Sub-Saharan Africa by the human population explosion of the 20th century. The laws were fine. CITES, as described, assumed that new laws were necessary, but thereby failed to address the real problem. Parker (2004) believes that there is a direct relationship between the decline in elephant populations, the annual 2-3% exponential increase in human populations in Sub-Saharan Africa, and the corresponding rate of uptake of new land. Loss of range is the critical issue (see Maasai Mara in Chapter 5, Section 5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya). Declining habitat makes recovery of a population irreversible. Ultimately, elephant populations declined from both legal [Problem Animal Control (PAC)] and illegal off-take along with reproductive failure brought about by disturbance, displacement and the severe stresses related to compression into even smaller ranges. Corruption's greatest influence was in how ivory was disposed and not so much in how it was acquired. Increasing human populations and loss of range determined that elephants must go regardless of

“whether the bullets that blew out their brains asunder were fired by colonial wardens who said they loved them or Amin’s soldiers who did not: what counted was their deaths” (Parker, 2004).

As discussed throughout this book, Parker (2004) believes that it is critical to address land and resource tenure, in which local communities can obtain the

2003

majority of benefits from elephant and other wildlife, if elephant habitat and thus elephant and other wildlife are to survive (see Chapter 9 in general and specifically Section 9.9.2, Land and Resource Ownership, Key to Success). All of this is independent of whether the price of ivory rises or falls (Parker, 2004).

Child, McKean, Kiss, Munthali, Jones, Mtsambiwa, Castley, Magome, Pangeti, Fearnhead, Johnson and Chilikusha (2004 *In:* Child, 2004) are concerned, especially with regards to elephants, that park managers and decision-makers are responding to the social aversion of an urbanized West to killing animals as a management tool (culling) to control populations, rather than dealing with shifts in ecological functions. Thus, the cost of protection and the failure of getting benefits to rural peripheral communities can be more costly to the environment from habitat destruction by both people and wildlife, than if management were allowed to occur that resulted in economic and ecological benefits. The risk is that the failure to undertake proactive management can result in over-stocking and long-term damage to ecological processes. Poverty knows no boundaries once people are in a survival mode, with the risks being habitat encroachment and accelerating poaching of elephant as a short-term resource. Child, *et al.* (2004 *In:* Child, 2004) believe that a shortcoming is obtaining adequate data from long-term ecological monitoring to quantitatively demonstrate the need for proactive management as wildlife becomes more confined in space and unable to disperse as parks and protected areas become surrounded by humans.

However, if a mistake is made in over-harvesting wildlife, most wildlife populations, including elephant, can recover in ten years, while once the habitat is destroyed, it can take 100s of years for the vegetation and 1000s of years for the soil to recover. Thus, preferences for non-consumptive uses and intangible uses that appear to be anthropogenic philosophical desires not to interfere with nature rather than any understanding of how an ecosystem functions, are often more

2004

consumptive than what is currently termed consumptive use (Child, 2004). Thus, ecosystem management becomes more important than single species management, and the adaptive management concept described in Chapter 9 allows for quick recovery if mistakes are made, much quicker than the precautionary principle espoused by the Western animal rights movement and researchers who would prefer to take no action, or study wildlife and ecosystems to extinction and/or irrecoverable ecological degradation.

Poachers probably helped do what the government was incapable of doing in the South Luangwa National Park, Zambia, by reducing the elephant population (Thomson, 2003; Rohwer, *pers. comm.*), whose damage to the environment could be viewed even in the early 1990s when the principal author undertook an evaluation of ADMADE.

10.4.5.1 Hwange National Park, Zimbabwe

Thomson (2003) gives an example of the build up of elephant in the 14,000 km² (5,000 mi²) Hwange National Park, Zimbabwe, despite their removal by government culling in the 1960s through 1987 (Table 10.6):

Table 10.6: Elephant population growth, Hwange National Park, Zimbabwe, 1900-2000

<u>Date</u>	<u>Elephant Population Hwange National Park</u>
1900	<100
1928	750
1960	6,000
2000	60,000

Source: Thomson (2003) with permission, Thomson.

Even by 1965, habitat damage by elephants was significant. He estimates a sustainable elephant population for this park to be at around 5,000. On Thomson's

2005

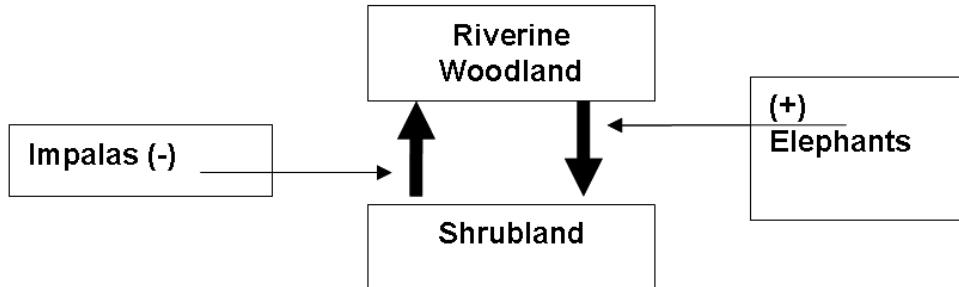

return to Hwange as the provincial game warden-in-charge in 1982, there were an estimated 21,728 elephants in the reserve and management decided to use culling to maintain the population at 14,000 or one elephant/km². The reduction target was never achieved. The independence of Zimbabwe in 1980 saw the loss of this expertise in the Wildlife and National Parks Department as significant numbers of white staff departed without training black game ranger culling teams.

In fact, in Zimbabwe, over a 17-year period from the late 1970s until the early 1980s, the national elephant population increased from 44,000 to 52,000 head despite the removal of 32,000 animals in a bid to reduce the alarming rate of habitat destruction (Child, 1993). Child (1995) states that between 1960 and 1991, the national elephant population of Zimbabwe, with a growth rate exceeding 5%, grew from about 30,000 to over 76,000 even though 46,775 elephants were removed by hunting and culling.

The 1989 CITES ban stopped the trade in ivory and skins that had been the source of money for such actions. Thomson calls this “Western first order thinking”, where Westerners impose their values and experience on other cultures and ecological systems without any attempt to understand the consequences. The Hwange National Park is a tragedy, which risks having nothing left in it but elephant and impala, which do well in degraded conditions feeding on regenerating tree seedlings, impala being what Thomson calls a “flip” agent, along with fire, in keeping the area in opened grasslands. This implies that once severe damage has occurred from elephant, impala numbers, possibly also other browsers, and fire may need to be controlled along with elephant to allow habitat and biodiversity recovery. du Toit also draws similar conclusions that the Chobe area next door to Hwange is in a state being maintained by impala (Figure 10.5).

A one-way transition:

- Elephants convert riverine woodland to shrubland
- Impalas (and other browsers) invade shrubland
- Seedling predation prevents the transition back

Source: Redrawn from du Toit, Moe & Rutina (2002) with permission, du Toit.

Figure 10.5: Role of elephant in moving from woodlands to savanna shrub and impala in keeping the ecosystem in shrub

A major difference in thinking between Thomson and du Toit is that du Toit as a researcher tends to favor “natural regulation”, letting nature play itself out. While Thomson, coming out of a park management background, strongly believes that given the artificial nature of most parks in the 21st century with little room for over-populated species to disperse, humans are obliged to actively manage for both biodiversity and economic reasons if these natural systems are to survive. Elephant has a great potential to provide income (trophy hunting, ivory and skin sales, along with transformed products and meat) for conservation and development, as well as to provide a major source of protein on a sustainable basis for Sub-Saharan Africa’s starving masses. Cumming (2005) estimates that

“a harvest of 5,000 elephants from a population of 200,000 elephants could generate US\$ 40 million a year – enough to protect and manage 200,000 km² of protected area at a rate of US\$ 200/km². National parks in Mozambique and Zimbabwe are currently operating on budgets as low as about US\$ 5 and US\$ 10/km², respectively”.

2007

In the late 1990s, the principal author sent his brother and nephew to visit the Victoria Falls with a side trip to Hwange. His brother's comment was that Hwange looked like a bombed-out war zone with the majority of trees leveled, elephants everywhere, a few herds of kudu and impala. He said that he would never come back to visit Hwange.

In most cases, there is a need for a drastic reduction in elephant populations and then an annual off-take equal to their annual incremental increase (e.g., 5-7%/year). The only economically viable solution, culling, must be considered. Translocation is possible, but it is very expensive, and countries like South Africa and Zimbabwe are finding that areas for translocation are limited and provide only short-term solutions. Elephant birth control to date has failed and even if it could work, why should elephant not be managed as an economic and protein resource for Sub-Saharan Africa. However, due to international pressure from Western governments and animal rights groups and roadblocks thrown up by CITES, culling is not taking place, which is resulting in de facto single species management for elephant, which devour up to 250 kg/day/elephant of vegetation. As they consume the last of Sub-Saharan Africa's biodiversity inside the parks and protected areas, over-populated humans and their livestock do the same outside these areas. Are Western ideas such as CITES and no culling so useful to Sub-Saharan Africa? How much better off would Sub-Saharan Africa, its people and their natural systems be if they were left alone to manage and market their resources?

In the opposite corner to Southern Africa's sustainable use philosophy is the Western urban-based animal rights movement epitomized by a statement in Leakey and Lewin (1995),

“To say no to culling is to recognize this species' (elephant) rights in a world in which we should coexist”.

2008

Cumming (2005) challenges this mentality and questions the morality of denying rural populations the right to improve their lives from living off elephant and elephant products (e.g., Chapter 9, Section 9.5.1, CAMPFIRE, Zimbabwe) while maintaining areas outside parks and protected areas in a natural state against the onslaught of agriculture. He also argues for parks and protected areas generating income from harvesting elephants so as to better manage these areas as centers for biodiversity. It is rare that the urbanized West thinks about these rural livelihood and management issues that will ultimately determine the future of elephant and other mega-fauna, along with their habitat. Destroying livelihoods and/or the ability of game/park departments to sustainably manage their natural resources will ultimately result in the demise of both the people and wildlife.

10.4.6 Elephant Down-listing to Appendix II in Southern Africa

It would take nearly a decade at the 1997 CITES COP 10 in Harare for Zimbabwe (export of 20,000 kg of ivory), Namibia (export of 13,800 kg) and Botswana (export of 25,300 kg) to have their elephant populations conditionally down-listed to Appendix II, allowing limited once off trade in ivory and some raw skin trade (CITES, 2005e). Each additional sale of ivory and/or skins, beyond typical hunting trophies as allowed by CITES, requires a proposal and approval at a COP meeting CITES (2005f).

COP 12 of 2002 saw South Africa's population of elephants down-listed to Appendix II with once off trade of stockpiled ivory being listed by early 2003 (CITES, 2005e).

Revenue from 1999 Sale of Elephant Ivory, Zimbabwe

The main characteristics of the 1999 auction, as agreed upon at CITES, was that the buyers would all come from a single country: Japan. The total value of the 19.9 metric tons of ivory sold was US\$ 2 million of which US\$ 520,195 went to 14 CAMPFIRE Rural District Councils (RDCs) (local government). Of this, US\$ 168,367 was dispersed to rural communities. The average price paid was US\$ 110/kg (Bond, 2001).

CITES trade controls on Southern African countries are restrictive and patronizing towards countries which have been leaders in conservation. The one exception to this is the one time world conservation leader, Zimbabwe, beginning with the politicization of land reform in 2000 that has had devastating impacts on wildlife; especially on game ranches (see Chapter 5. Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife).

10.4.6.1 Botswana

By COP 12 in 2002, Botswana was allowed trade in (CITES, 2005e):

1. Hunting trophies for non-commercial purposes – tusks from 210 trophy hunted elephant (CITES, 2005f);
2. Live animals for in-situ conservation programs;
3. Hides;³³¹

³³¹ Caldwell (2005a) believes that hides mean tanned and untanned. The author was always told this meant untanned raw hides. According to Heath (2005), from a practical standpoint and to meet international veterinary restrictions, elephant hide is partially “blue tanned”, the color of a hide coming out of chromium tanning solution, making it 17-25% lighter than a salted hide and much cheaper to ship, while assuring that disease transmission cannot be a problem as a result of this preliminary treatment process.

2010

4. Leather goods for non-commercial purposes;
5. Registered raw ivory (whole tusks and pieces only from registered government-owned stocks, originating in Botswana), excluding seized ivory and ivory of unknown origin, to trading partners verified by the secretariat, in consultation with the standing committee, to ensure that the imported ivory will not be re-exported and will be managed in accordance with all requirements of Resolution Conf. 10.10 (Rev.) concerning domestic manufacturing and trade and not before May 2004 and before the secretariat has verified the prospective importing countries and the Monitoring of Illegally Killed Elephants (MIKE) program has reported to the secretariat on the baseline information (e.g. elephant population numbers, incidence of illegal killing); and
6. Proceeds spent on elephant conservation and community conservation and development programs within or adjacent to the elephant range.

“A maximum amount of 20,000 kg of ivory may be traded, and dispatched in a single shipment under strict supervision of the Secretariat...”. (CITES, 2005e). At CITES COP 13 of October 2004, it was determined that the six conditions of COP 12 applied to trade, as well as the quantity of ivory that could be sold (CITES, 2005e). This was still the case in 2005 (CITES, 2005e). In addition to trophy hunted tusks, to date the following has been exported from Botswana (Table 10.7):

Table 10.7: Export of elephant parts, 1998-2004, Botswana							
PRODUCT	UNIT	1998	1999	2000	2001	2002	2003

Skin Pieces		0	0	4	0	0	2
Leather Products				1			0

Source: CITES (2005g) & UNEP-WCMC (2005b) with permission, Jon Hutton Director, United Nations Environment Program- World Conservation Monitoring Center (UNEP-WCMC).

2011

To date only one major ivory sale has taken place for Botswana, Namibia, South Africa and Zimbabwe with a second sale being planned but not yet having taken place as of June 2005, the second sale excluding Zimbabwe (Botha, 2005).

10.4.6.2 Namibia

By COP 12 in 2002, Namibia was allowed trade in elephant ivory and parts with basically the same conditions as Botswana but a maximum amount of 10,000 kg of ivory in a single shipment (CITES, 2005e) and tusks from 90 trophy hunted elephant (CITES, 2005f). In addition to trophy hunted tusks, to date the following has been exported from Namibia (Table 10.8):

Table 10.8: Export of elephant parts, 1998-2004, Namibia

PRODUCT	UNIT	1998	1999	2000	2001	2002	2003	2004
Tusks	kg	0	12,366	0	0	0	0	0
Skin Pieces		0	0	0	0	0	471	0

Source: CITES (2005g) & UNEP-WCMC (2005b) with permission, Jon Hutton Director, UNEP-WCMC.

At CITES COP 13, it was determined that the six conditions of COP 12 as noted for Botswana applied to trade for Namibia with one exception; trade in leather goods could be for non-commercial and for first time commercial purposes as well as for the first time trade in elephant hair for commercial and non-commercial purposes. Trade was also allowed in *ekipas*³³², incorporated in finished jewelry for non-commercial purposes. The once off export remained at 10,000 kg not to be sold before May 2004 (CITES, 2005e). Based on Table 10.8, the sale had not yet taken place in 2004. The same amount of ivory is repeated for a once off sale in 2005 as were the other six conditions, so it is believed that the stockpile sale was carried over (CITES, 2005e) as per Botha (2005).

³³² Traditional ornament worn by women of the Owambo tribe

10.4.6.3 South Africa

By COP 11, South Africa could trade in elephant hides and leather goods. By COP 12 in 2002, South Africa was allowed to trade in elephant ivory and parts with the same conditions as Botswana but a maximum amount of 30,000 kg of ivory in a single shipment (CITES, 2005e) and ivory/parts from 100 trophy hunted elephant (2005f). By COP 12, leather goods were stipulated only for non-commercial trade. In addition to trophy hunted tusks, to date the following has been exported from South Africa (Table 10.9):

At CITES COP 13, it was determined that the six conditions of COP 12 applied to trade with one exception; trade in leather goods could be for non-commercial and for first time - commercial purposes. The once off export remained at 30,000 kg and only ivory originating from the Kruger National Park (CITES, 2005e). This was still the case in 2005 (CITES, 2005e). Based on trade statistics (Table 10.9), it appears that the once off sale of stockpiled ivory had not taken place and was carried over into 2005 as per Botha (2005).

Table 10.9: Export of elephant parts, 1998-2004, South Africa

10.4.6.4 Zimbabwe

By COP 11 in 2000, Zimbabwe could trade as per Botswana but had no right to sell ivory stockpiles as had been allowed at COP 10 in 1997 (up to 20,000 kg once off that took place in 1999) (CITES, 2005e). COP 11 in 2000 allowed Zimbabwe to trade in elephant parts, but indicated no sale of stockpiles (CITES, 2005e). By COP 12 in 2002, (as indicated in early 2003, 13/02/03) and COP 13 of 2004, Zimbabwe is not listed as having the right to trade in any elephant parts (CITES, 2005e). According to Caldwell (2005a), the Zimbabwe listing for July 7, 2000 in CITES (2005e) still allows Zimbabwe to export live animals and continue with the export of tusks from 500 trophy elephant (CITES, 2005f), which as a result of CITES Resolution 911 is considered non-commercial, and to export hides and transformed ivory/leather for non-commercial purposes with all other trade being regulated as if the elephant were on CITES Appendix I. To date the following has been exported from Zimbabwe (Table 10.10).

Table 10.10: Export of elephant parts, 1998-2004, Zimbabwe

Source: CITES (2005g) UNEP-WCMC (2005b) with permission, Jon Hutton Director, UNEP-WCMC. (s) = small, (l) = large

2014

There is a large difference between the 19,900 kg sold in 1999 as indicated by Bond (2001) and as provided for by CITES COP 10 compared to that found in Table 10.10 extracted from UNEP-WCMC (2005b).

The UNEP-WCMC CITES database manager (Caldwell, 2005b) indicated that the figure of 95,330 kg is in error,

“I have looked more closely at the Zimbabwe annual report for 1999 and it appears that the erroneous record for 74,910 kg (95,330-74,910 = 20,420 kg, similar to the 20,000 kg export allowed by COP 10) was for either 7 tusks or, more likely, 7 carvings...I will try to follow these up with the Management Authority of Zimbabwe but don't hold out much hope of getting a response. Their report is always awash with typographic errors, many of which I can sort out by cross checking with data from the importing countries” (Caldwell, 2005b).

“Zimbabwe (ZW) did not report the commercial export of the stockpiled ivory while the Japanese did report the import. Thus the total gross export figure of 95,330 kg includes both the erroneous record of export to South Africa and the correctly reported Japanese import record...I suspect the (South African) permit was cancelled and replaced subsequently” (Caldwell, 2005c).

Caldwell (2005d) goes on to explain that

“a record reported by ZW of over 70t (tons) going to South Africa - this was an error. There was a record of 20t + going to Japan, reported by Japan - this was the one-off sale, not reported by ZW. The gross/net program added these together to produce the 93t + figure. Hopefully I've amended the database to reflect the true situation in future outputs”.

Parker (2004) states that CITES statistics were flawed, with 95% of animal exports reported not tallying with import statistics, what he calls “a total monitoring failure”.

2015

Likewise, Botha (2005) of the Department of Environmental Affairs and Tourism, South Africa, has the following to say,

“Zimbabwe had permission to sell 20 tons of ivory and that accounts for the 19,900 kg. I cannot make out where the 93 tons are coming from. One must bear in mind that the WCMC figures will represent all ivory, that is bracelets etc, but for that to come to 93 tons is a bit much. I will believe the figures from Bond as the real figures from Zimbabwe. There was only one sale and as a matter of fact Zimbabwe has not been included in the second sale it is only South Africa, Botswana and Namibia and this sale has not taken place yet”.

In addition, what the UNEP-WCMC trade database does not appear to show in addition to sport hunted trophies is the “non-commercial trade” that flourishes in Zimbabwe. This consists primarily of *hanko* (oriental seals) and chopsticks amounting to 5-6 tons of elephant ivory/year. Non-commercial trade in this case is considered an export of five items or less of a value of US\$ 500 or less. CITES export permits are issued by the Zimbabwean authorities for each shipment but would not be recorded as commercial trade (Heath, *pers. comm.*). Using this loop hole, Johnson (2006) estimated the export to China over a seven month period of 30 tons of ivory representing 2,250 Zimbabwean elephants (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife - Impacts of Land Reform on Wildlife and the Environment).

It is unclear as to whether this definition applies to other countries. However, once again as per Parker (2004) concerning the flawed database, Caldwell (2005d) gives one the impression that this gross trade data should include trophy hunted tusks and other non-commercial trade. It is clear from Tables 10.6-10.9 that trophy hunted tusks are not included between 2000-2004, which makes one wonder about the accuracy of any of this data.

2016

Courtney Boots, an Example Close to Home, CITES as an Impediment to Free-trade

Courtney Boots, based in Bulawayo, Zimbabwe, makes one of the finest outdoor, casual and hunting lines of boots in the world from game skins including elephant. Zimbabwe has a CITES quota for elephant skins. Elephant skins are said to be worth more than ivory. Zimbabwe can export untransformed elephant hides to America, where Americans turn them into cowboy boots and other products, getting the added value of transformation in America. Since Zimbabwe has “no permission” from CITES to export products from transformed elephant hides for commercial purposes, Courtney Boots is restricted to small quantity non-commercial sales as opposed to the vast international market. According to Heath (2005), in the case of the United States, it has taken “stricter domestic measures” and only allows trophy hunted elephant ivory and parts into the country, but no other form of non-commercial trade in elephant ivory/parts. Only raw “blue tanned” hides are sold to the United States from Zimbabwe. It would seem that this flies in the face of the New Partnership for Africa’s Development (NEPAD). Each country has different export guidelines and must make individual requests to CITES. It is time that Zimbabwe, like Namibia and South Africa at COP 13 in 2004, requests quotas for the export of transformed commercial leather products. The precedent for the first time has been set. Of course this means nothing if the importing country, as the United States, disallows importation.

10.5 RHINO, TRADE OR TRADE CONTROL, WHAT'S BEST FOR CONSERVATION?

The IUCN Southern Africa Sustainable Use Specialist Group argues that nowhere in Southern Africa has giving value to natural resources resulted in their being mined to extinction. In fact, they argue,

“...the black rhino - has suffered a catastrophic decline in the region (Mozambique, Zambia and Zimbabwe) but this has come about because no legal financial value was attached to the species, the special protection afforded to the species through legislation effectively removed the incentives for local communities to conserve it...” (IUSN/SASUSG, 1997).

At about the same time as an ivory market developed, a demand developed for rhino horn for dagger handles in the Middle East and medicine in Asia. Medicinally, rhino horn is believed to have value as a blood thinner and in fever reduction (febrifuge), but not as an aphrodisiac as often purported (Duffy, 2000), fulfilling the role that aspirin plays in Western medicine (Parker, 2004). Both black and white rhino are listed on CITES Appendix I, except the South African white rhino population which is Appendix II (SCI, 1996) and is legally trophy hunted. The trade in rhino horn was banned through CITES in 1977, while the world rhino population between 1970 and 1990 declined by 80% (Duffy, 2000). Between 1975 and 1980, the black-market post-ban value of wildlife increased 20 times linked to illegal trading syndicates, which CITES unintentionally helped to create (Duffy, 2000). The black rhino was protected to near extinction, the trade ban failing, while South Africa brought the southern white rhino back from near extinction by giving it value through trophy hunting (Table 10.11).

Table 10.11: White rhino (*Ceratotherium simum*) population recovery – South Africa

YEAR	NUMBER	SOURCE

2003	11,350	Emslie (2007)
2005	14,540	Emslie (2007)

From October 1, 1998 to November 31, 1999, 43 hunted/year in South Africa, generating US\$ 1.1 million/year in trophy fees alone (Hoogkamer, *pers. comm.*). About 20% (one-fifth) are on private land.

Table prepared by principal author with permission Emslie and International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU).

The future of the black rhino will depend on collaboration between nature conservation agencies, private farmers and trophy hunters. In 2005, the first black rhino was sold to a safari operator for about \$US 220,000 hunted in Pilanesberg Park, Northwest Province, South Africa (Hoogkamer, *pers. comm.*) and a complete hunt was sold for US\$ 150,000 in Mpumalanga Province, South Africa (Hunting Report, 2005). In 2006, a black rhino hunt is selling for about US\$ 100,000 (Hoogkamer, *pers. comm.*). Duffy (2000) estimated the value as US\$ 250,000/trophy hunted black rhino. About 74% are found on state land, 15.1% custodianship on private land and 2.4% in private ownership. The drop in 1995 is due to a change in statistics – no more estimates taken – only actual census data. About 40% of the current population is found in South Africa (Emslie & Brooks, 1999 *In: African Advisory Board, 2000*) (Table 10.12).

Table prepared by principal author with permission, Emslie and International Union for the Conservation of Nature (IUCN)/World Conservation Union (WCU).

The virtual elimination of black rhino from much of their range in Africa is due to the high value of their horn. Zimbabwean populations were not affected until recently, since poaching spread south from the Horn of Africa, and because in Zimbabwe they were a hard target first protected by civil war and then by a high level of law enforcement (Duffy, 2000). Rodgers (2005 *In:* Baldus, 2005) gives the example of the Selous Game Reserve (SGR) black rhino population of over 3,000 driven to near extinction from the poaching of the 1980s. See Chapter 9, Section 9.6.1.1, Zambia for a brief discussion of black rhino extermination in Zambia.

As with elephant, Parker (2004) believes that the decline in black rhino can also be linked to loss of range from growing human populations. In East Africa, black rhino lost 82% of its range between 1925 and 1970, the greater part of the loss

happening before 1950. The decline in rhino moved south regardless of the kind of governance and regardless of the price of horn.

Kingdon (1971 *In:* Parker, 2004) demonstrates that trade does not appear to impact wildlife where the range is intact, nor is there necessarily a direct link between trade and declines in a species. Kingdon (1971 *In:* Parker, 2004) examined changes in distribution of 30 large mammal species in Sub-Saharan Africa, all of which had declined through the half century preceding 1970. There was not necessarily a relationship between extent of range loss and value of trophy. The Ugandan kob was No. 1, having lost 89% of its range and corresponding numbers,³³³ with little value for trophy and hide, except for meat. Leopards lost less of their range than all but two species despite the value of their pelts. In 1987, CITES consultants noted that the trade in leopard skins, ranking with elephants and rhino in value, had a negligible impact on leopard numbers (Martin & de Meulenaer 1987- *In:* Parker, 2004). Wildlife such as kudu, oryx and gerenuk that live in dry areas, where they can go for a number of months without free water, lost less of their range than those species living in areas suitable for agriculture. In other words, Parker (2004) argues that the decline in elephants and black rhinos and other large mammals has everything to do with human increase, displacement by people and ultimately loss of range and very little to do with the value of their products. These declines have been going on throughout the past century and are not just a post-1970 phenomenon. Parker (2004) believes placing all the blame on African governance to be racial and dishonest. Parker (2004) also believes that CITES is a waste of money and that it fails to address significant issues. The “good cops bad poacher” story makes for first-class fundraising by Western NGOs while discussing over-population, poverty and disenfranchisement does little to entice Western audiences to open their purses.

³³³ Elephants and rhinos were second and third, respectively in loss of range (Parker, 2004).

In 1983, CITES declared a complete ban on trading in rhino parts and derivatives. Illegal trade flourished. The Department of Wildlife and National Parks in Zimbabwe increased its anti-poaching levels within the limitations of manpower and finance. Rhino were also relocated into safe areas within the parks and wildlife estate. Poaching suddenly escalated in the Zambezi Valley. Rhino dehorning failed since “poachers” were unable to determine if a rhino was dehorned in thick bush and the Far East was counting on the extinction of the black rhino driving up the value of stockpiles (Duffy, 2000). By mid-1985, the prime minister, with support from President Robert Mugabe, authorized the shooting of poachers in self-defense (Child, 1995), Operation Stronghold and eventually Operation Save Our Heritage in 1993, even providing rewards for each poacher shot or caught. Between 1984 and 1993, 170 poachers were killed, the majority being Zambian. In America and Europe, the killing of “poachers” was presented as a global good (Duffy, 2000). Human rights groups condemned this policy of shooting people without proving their guilt while protecting the killers through the 1989 Protection of Wild Life (Indemnity) Act that exonerated game guards who shot so-called poachers. This caused strained relations between Zambia and Zimbabwe, though President Kaunda eventually backed this war on poachers in an effort to maintain relations with Zimbabwe. It was estimated that the cost of protecting the black rhino was US\$ 400/km² while by 1988 as the result of structural adjustment (SAP) there was only US\$ 24/km² available for this purpose (Duffy, 2000).

Duffy (2000) attributes the increase in poaching of Zimbabwean black rhino to: 1) increase in supply of weapons as a by-product of civil wars, liberation wars and superpower competition, 2) a major economic decline in neighboring Zambia, from where most of the poachers initially came, due to the World Bank/IMF structural adjustment policies (SAPs) (see Chapter 12, Section 12.7.1.12, Impacts

of structural adjustment on the wildlife and parks estate in Zimbabwe), 3) increased complicity and support of poachers by Zimbabwean nationals and 4) a triangular network of politicians, business people and diplomats who helped move the black rhino horn and eventually elephant ivory, once the black rhino had been shot to near extinction. Law enforcement was tackling the effect rather than the cause of the problem; the high price of horn on the illegal market was given a monopoly by the prohibition of legal trade. The approach, based on protectionist philosophies that depended on persuading people to shut down the lucrative trade in rhino products, was misguided (Child, 1995). By 1992, Zimbabwe had an estimated 240-350 black rhino out of what had been the largest remaining population in Africa of an estimated population of 3,000. CITES had failed to protect black rhino across the continent, as states lost their ability to derive income from regulated trade while poachers, middlemen and dealers captured the economic value in a thriving black market (Duffy, 2000). Just as importantly, on the ground “poachers”, mainly rural poor, became the victims of the real culprits - middlemen (politicians, businessmen, game department officials and diplomats), who were rarely caught, protected by their status in society and who took advantage of poverty in the region, exasperated by the structural adjustment policies (SAPs) imposed on the region (Duffy, 2000). Likewise, Parker (2004) feels that innocent men were being shot as they ran away, while the real culprit behind the scene in black rhino poaching was South Africa. As noted, the contraband trade in ivory and rhino horn in Southern Africa in the 1980s/90s is alleged to be largely by South Africa, often in collaboration with ex-Rhodesian Selous Scouts. This was both for personal gain and to help fund many of its wars against liberation and communism, including rebel groups such as National Union for the Total Independence of Angola /*União Nacional Para a Independência Total de Angola* (UNITA) in Angola and *Resistência Nacional Moçambicana* (RENAMO) in Mozambique (Potgieter, 1995; Meadows, 1996; Parker, 2004).

2023

The black rhino were eventually moved to private conservancies in Zimbabwe, when the state was unable to protect them and were beginning to recover. Zimbabwe had the world's largest single remaining herd of black rhino, numbering about 500. However, since the radical land reform of 2000 and associated economic collapse, it was reduced to 200 from poaching by 2004 (Unti, 2007) and by a further 80 from poaching in the first three months of 2007 (VOA, 2007) (see Chapter 5, Section 5.7.4.1, Politicization of land reform in Zimbabwe, impacts on food production, the economy and wildlife). This decline cannot be attributed to bad conservation, or the need for more trade controls that would not stop this plunder, but the destruction of a country by greed and a lust for power of Robert Mugabe and his cronies in the Zimbabwe African National Union – Patriotic Front (ZANU-PF).

It is interesting that animal rights and their spokesman Richard Leakey (Leakey & Morell, 2002) believe that banning the trade in elephant ivory will protect the elephant, when he admits that,

“more rare than elephant, rhino horn has been banned as an item of international trade for some years but fetches very high prices on the black market. A single rhino horn can attract several thousand dollars at the first point of sale and by the time it reaches Taiwan or China can be worth almost 10 times that”.

It can be argued that on one hand CITES helped condemn the black rhino to near extinction, while careful conservation efforts by the South African government, landowners and sport hunters helped save the white rhino. Which route would you chose, trade or preservation? The answer is self-evident in the figures provided above.

10.6 CITES RESOLUTION 2.11

In 1979, the CITES parties adopted Resolution Conf. 2.11, dealing with the international shipment of sport hunting trophies of species listed on Appendix I. According to the sponsors, the purpose of the resolution was to correct the “differing procedures (for) the granting of permits for the trade in hunting trophies of Appendix I species”. Instead, it caused further confusion, expense and delay (CITES, 1994a).

Between 1979 and 1994, “tourist safari hunting” and the taking of a low number of trophies of Appendix I species became accepted as an important conservation measure to help assure the survival of the species through income from hunting being poured back into community development schemes, anti-poaching and habitat management.

However, some countries used Resolution 2.11 as a rationale to refuse CITES approved trophy-hunting quotas for importation into their countries.

The USA’s reluctance to issue trophy import permits ultimately lead to litigation with the tourist hunting (sport hunting) industry. In turn, this led to an amendment of Resolution 2.11 at COP 9 in Fort Lauderdale, Florida, in 1994 to protect the emerging sustainable use conservation programs of the independent African states from protectionists’ political influence in the administration of the Endangered Species Act (ESA) and of CITES authorities in the USA. The U.S. Secretary of Interior even admitted in his address to the CITES parties that the USA was being accused of undermining the means and funding of the African states program through excessive precautionary restraints on trophy imports. Under revised Resolution 2.11, trophies from sport hunting are considered as non-commercial trade. The sovereignty of a state is respected, the parties assuming

that a requested trophy-hunting quota by the exporting country is “non-detrimental” to the species (Jackson, *pers. comm.*). To quote the CITES Resolution: Amended paragraph (c) of Resolution Conf. 2.11 reads as follows (CITES, 1994b; 1994c):

“CONSIDERING the need of uniform interpretation of the Convention with regard to hunting trophies;

...b) in order to achieve the envisaged complementary control of trade in Appendix-I species by the importing and exporting countries in the most effective and comprehensive manner, the Scientific Authority of the importing country accept the finding of the Scientific Authority of the exporting country that the exportation of the hunting trophy is not detrimental to the survival of the species, unless there are scientific or management data to indicate otherwise...”

Thus, the role of the exporting country is to assess the impact of the removal of the animal from the country’s wild population. The importing country’s role is to consider the purpose or use of the importation into the importing country (CITES, 1994a).

“The resolution was amended at COP 9 to reflect the original intent of the parties when CITES was adopted. The biological non-detiment determination of export nations is generally to be accepted because 1. they are in the best position to know and to make that determination, 2. respect of sovereignty, 3. importing nations are to make a different though complementary determination that relates to the ultimate use and destination, i.e., the ultimate purpose of the import which they are in the best position to make, 4. to avoid burdensome and arbitrary stricter domestic measures of importing states, 5. because range nations, according to the CITES preamble are the owners of the species and are preferred to manage their own species, 6. that was the original intent, i.e., any other interpretation is *ultra-vires*” (Jackson, 2006a).

10.7 ENDANGERED SPECIES ACT OF THE USA, IMPEDIMENT TO AFRICAN CONSERVATION

The U.S. Congress passed the Endangered Species Preservation Act in 1966, which allowed listing of only native animal species as endangered. The Endangered Species Conservation Act of 1969 provided additional protection to species in danger of “worldwide extinction”. Import of such species was prohibited, as was their subsequent sale within the U.S. This act called for an international ministerial meeting to adopt a convention on the conservation of endangered species; CITES adopted in 1973. The Endangered Species Act (ESA) of 1973 combined and considerably strengthened the provisions of its predecessors. Its principal provisions follow (USFWS, 2003):

- U.S. and foreign species lists were combined, with uniform provisions applied to both (section 4);
- Categories of “endangered” and “threatened” were defined (section 3);
- Plants and all classes of invertebrates were eligible for protection, as they are under CITES (section 3);
- All federal agencies were required to undertake programs for the conservation of endangered and threatened species and were prohibited from authorizing, funding or carrying out any action that would jeopardize a listed species or destroy or modify its “critical habitat” (section 7);
- Broad taking prohibitions were applied to all endangered animal species, which could apply to threatened animals by special regulation (section 9);
- Matching federal funds became available for states with cooperative agreements (section 6);
- Authority was provided to acquire land for listed animals and for plants listed under CITES (section 5); and
- U.S. implementation of CITES was provided (section 8).

Significant amendments have been enacted in 1978, 1982 and 1988, while the overall framework of the 1973 act has remained essentially unchanged (USFWS, 2003). Under the ESA:

- **Endangered** applies to any species considered to be in danger of becoming extinct throughout all or a significant portion of its range; and
- **Threatened** refers to any species that is likely to become an endangered species throughout all or a significant portion of its range within the near future.

In order for a species to be listed, there must be enough information to support the proposed listing of that species based on its biological status and on the severity of threat placed on its existence. Species can only be determined as endangered or threatened by one or more of the factors listed below:

1. If there is present or threatened destruction and alteration of its habitat;
2. If there is an over-utilization for commercial, educational and/or scientific purposes;
3. If there is a presence of disease or predation;
4. If there are not enough regulatory mechanisms existing today to protect the species; and
5. If there are any other natural or man-made factors that may be or currently affecting its continued existence.

When there is not enough biological information on a species for the Fish and Wildlife Service to issue a classification of endangered and threatened, the species is referred to as a "candidate species" (FLMNH, 2003). The ESA, like CITES, has a reputation for listings, often made based on political rather than scientific bases.

For instance, in the early 1970s, all spotted cats were listed as “endangered” by the USFWS on the basis of one NGO’s petition that they were listed on Appendix I of CITES. It takes more information to delist a species from the ESA than to list it. For instance, recent attempts in 2002/2003 to down-list the cheetah population in Namibia failed because of inadequate population data and yet more is known about the status of the Namibian cheetah population today than when it was listed on the ESA (Jackson, 2003). Jackson has argued that the original listing of the Namibian cheetah as “endangered” in the ESA (USFWS, 1999) was in error, the cheetah from Namibia being lumped with other cheetah populations on the supposition that there was excessive commercial trade in skins, but with little or no evidence. Jackson (*pers. comm.*) argues that this is “fallacy of composition or division”, recognized as invalid reasoning for 2,000 years and therefore unscientific. It is invalid to assume that what applies to a group as a whole is equally true of all members of a group, i.e., that the Namibian cheetah were at the same risk as cheetah elsewhere.

On August 28, 2003, the USFWS published a proposed change in ESA policy to allow, under certain conditions that are beneficial to conservation, the importation of trophies of foreign species listed within the act as “endangered” (see 159 FR 49512). If adopted, the U.S. will allow the import of trophies of “endangered” species taken in regulated hunts in foreign countries (never adopted). This proposal is supposed to encourage foreign conservation programs that enhance the hunted species. The ESA and regulations to implement it have always authorized importation of trophies of animals listed as “endangered” if the hunting “enhances” the survival of the species. Over the 30-year history of the ESA (enacted 1973), a practice has evolved against such permits. No trophy import permit has ever been issued for any “endangered”³³⁴ species on the ESA hunted in

³³⁴ Note: Note: Elephant, and Leopard (in the wild, south of, and including, the following countries: Gabon, Congo, Zaire, Uganda, Kenya) are “Threatened” under the ESA (1999), the next category down. Leopard north of this line, “Endangered” under the ESA.

the wild. This includes cheetah in Namibia, jaguar in Central/South America, the Argali sheep in China and the Markhor sheep in Asia (Hutton, 2003). The one exception has been the “farmed” but “endangered” in the ESA bontebok (*Damaliscus dorcas dorcas*) from South Africa where import permits for hunted bontebok trophies are available from certified South African ranches on a U.S. approved list (SCI, 1996). The bontebok survival has been advanced by the managed captive breeding, culling of surplus males on game ranches and related revenue from tourist hunting (sport hunting) by Americans (WCF, 2005). As this chapter was prepared, the animal rights were mounting extreme opposition to the change in this policy. Some say that the USFWS fears a major lawsuit by the animal rights groups the day it lets a hunted trophy in of a species taken from the wild on the ESA endangered list.

10.7.1 ESA as an Impediment to Cheetah and Black-Faced Impala Conservation in Namibia

One example is Namibia’s cheetah (*Acinonyx jubatus*), which is classified as “endangered” in the ESA (USFWS, 1999), cheetah from all over Africa being thrown into one barrel. In Namibia, the cheetah is anything but endangered (Table 10.13) and found on game/cattle farms where it kills almost daily.

Table 10.13: Cheetah populations, Namibia

DATE	NUMBER	SOURCE
1900	??????	Grellmann, <i>pers. comm.</i>
1999	1,580 – 5,040	MET (1999)
2004	3,318 – 5,775	Hanssen & Stander (2004)

Source: DeGeorges *In: African Advisory Board* (2000).

2030

Establishment of cattle ranches in Namibia resulted in an elimination of lion and hyena in the 1930s/40s. These predators traditionally suppressed the cheetah population by out-competing the cheetah for food and killing its young. By the 1970s, the cheetah population had increased to the point where ranchers considered it unwanted vermin (Grellmann, *pers. comm.*).

Although Namibia has a CITES export quota of 150/year (CITES, 2005b), currently only about 60 trophy hunted cheetah/year are exported (Grellmann, *pers. comm.*) mostly to Europe. Trophy hunted cheetah are not allowed into the USA, the cheetah being “endangered” on the ESA (USFWS, 1999). For about six years, the international hunting community has attempted to show “enhancement” as required under the ESA (see next sections) by each successful hunter donating ND 1,000 (\approx US\$ 100-150) into a Cheetah Conservation Fund to be administered by the Namibian Nature Foundation for research. The Namibian Professional Hunters Association (NAPHA) even developed a hunter’s code of ethics for the cheetah. The USFWS has rejected these attempts at conservation.

Cheetahs in Namibia are mainly found on private ranches. It is estimated that 120/year are shot as vermin (African Advisory Board, 2000). This is a minimal estimate, some saying that up to 900/year may be shot in Namibia as vermin. If the CITES quota was respected by importing countries, it would go a long way in stopping the indiscriminate slaughter of cheetah by turning them into an economic resource (Grellmann, *pers. comm.*).

Similarly, on ranches in northern South Africa, especially in the Limpopo Province, cheetah populations have grown to the point that they are a nuisance. Game ranchers are lobbying the South African government to obtain a CITES quota. Even when they do, unless there are changes in the ESA, their biggest

market, America, will not be available and like in Namibia, ranchers will “shoot, shovel and shut-up”.

Giving value to the black-faced impala (*Aepyceros melampus petersi*) from hunting as a unique subspecies will encourage stewardship by game ranchers. Currently, an estimated 3,000+ black-faced impala reside mostly in Namibia (Hamunyela, *pers. comm.*). In Namibia, about 50% of the population is found on commercial farms and 50% in the Etosha National Park. Angola had 600 in 1975 (Huntley, 1992) and today no more than a few dozen remain (Griffin, *pers. comm.*).³³⁵ The black-faced impala is “endangered” in the ESA (ESA, 1999). The biggest threat to the black-faced impala in Namibia is hybridization with the common impala (*Aepyceros melampus*), and past war in Angola and associated poaching. In the future, registered pure-bred farms will be required to protect this species in Namibia (Grellmann, *pers. comm.*). Namibia’s Ministry of Environment and Tourism (MET) has implemented a black-faced impala program. Populations will be censused and genetically verified for purity. An east/west boundary will be identified separating common (south of line) and black-faced (north of line) impala near the southern boundary of the Etosha National Park. Buffer farms will be established where no impala will kept. Pure stock south of this boundary will be identified, and secured with fencing and buffer farms (De Jager, *pers. comm.*).³³⁶ Despite

“a ‘second draft’ Special Report (46 pages) on the black-faced impala and ‘second draft’ Draft Management Plan specifically ‘prepared for The Ministry of Environment and Tourism of Namibia, Conservation Force (USA)’ ” (Jackson, 2006b),

importation of black-faced impala is still being contested.

³³⁶ Mich De Jager, Ministry of Environment and Tourism (MET), Wildlife Management & Utilization, Namibia

10.7.2 “Enhancement” Requirement under the United States "Endangered Species Act (ESA) "

For animals listed under the U.S. Endangered Species Act (ESA), the Office of Scientific Authority (OSA) asks,

“Does hunting/killing of an animal enhance the survival of the species”?

Under ESA, it must be scientifically determined that use for scientific purposes, hunting, etc. will enhance survival of endangered species. If OSA finds enhancement, then the Office of Management Authority (OMA)³³⁷ will issue a permit (Jackson, 2002). Unfortunately, use of “enhancing a population/species” (making things better for a species) under the U.S. Endangered Species Act is much more difficult to prove than use being “non-detrimental to a population/species” (impact is not negative to the species) under CITES. This is especially the case, when the USFWS continues to move the “goal post” in what they expect from an exporting country with regards to “enhancement”. This goes against the spirit of CITES Resolution 2.11 in which the importing country is supposed to respect the non-detrimental findings of the exporting country on accepted CITES quotas for trophy hunted species on Appendix I of CITES (Section 10.6, CITES RESOLUTION 2.11). Enhancement was rejected by CITES and was removed from the original Resolution 2.11 (Jackson, 2002). In essence, the USFWS is saying, “We do not trust your judgments, and we insist on replacing your views with our own”. The latest, USFWS internal guidelines for permitting import of Appendix I hunting trophies indicate the continued use of enhancement; the animal or plant from the wild being part of a “biologically based sustainable-use management plan” (U.S.

³³⁷ Each signatory to CITES is required to have an OSA and OMA

Federal Register, 2007) whose goal posts can be continually moved as indicated in this analysis.

10.7.2.1 “Enhancement” under the ESA linked to CITES, condemning more wildlife to die?

USFWS issued a formal notice about six years (2000) ago proposing adoption of “internal guidelines” contrary to Resolution 2.11(Rev.) of CITES that governs trophy imports. The proposal is still open without a final rule (Jackson, 2002).

“If the USF&WS adopts the ‘internal guidelines’ or if it practices them anyway as with current Cameroon trophy hunting import permits on appeal, the cost of keeping hunting open for CITES Appendix I and Appendix II species will become prohibitive. The anti's will have a field day. Developing nations will no longer view sport hunting as a practical option” (Jackson, 2002).

“While controversial, currently, the Office of Management Authority (OMA) is demanding enhancement under CITES before it okays issuing an import permit for sport hunted trophies of species listed on CITES Appendix I (Endangered, such as the African Elephant). They say this is consistent with the purpose of the ESA. OSA says that the OMA has the right to be more rigorous for endangered species!! Thus the US Government takes ‘Stricter Domestic Measures,’ as allowed under CITES.

Though the ‘internal guidelines’ have not been formally adopted, they appear to have been informally adopted. The OSA is going beyond its recognized authority in determining the ‘purpose’ (upon reaching the importing country) is not detrimental. It’s requiring proof of ‘enhancement’ and ‘management’ to its liking before it issues permits for trophy hunted animals with CITES Appendix I quotas. If the species is endangered and threatened under the ESA, OSA will make a Biological Assessment of the species. OMA reviews this assessment by OSA and usually accepts their finding as basis of the ‘Enhancement Finding’.

At this time the USF&WS is only demanding graduated steps of achievement from developing nations but it is not possible for a lay

applicant to know what steps or progress the Service wants or will find acceptable each successive new permit year. (The fact that they will accept progress instead of a finished or perfected program is itself a victory of sorts that our fighting has brought into existence as a compromise.) Permits have to be filed and denied to even discover what the USF&WS wants. Most of the time the Service does not know what it wants either, at least not until it is put before them through the processing of a permit" Jackson, 2002).

"Organizations like Safari Club International have taken a position that it is improper private inurement to a member to help a permit applicant. Yet, no private individual can afford the hundreds of thousands of dollars of legal cost" (Jackson, 2002).

"The enhancement examination is being arbitrarily applied, but it also has no ESA legal basis. The ESA Final Rule for elephant trophy imports provides only one basis for the 'enhancement' requirement and that basis no longer exists. It was based wholly and exclusively on the U.S. Fish and Wildlife Service's misinterpretation of CITES Resolution Conf. 2.11 that was subsequently revised by the Parties to eliminate that very misinterpretation. The 'enhancement' language was deleted from the Resolution after the adoption of the ESA Special Rule" (Jackson, 2002).

"At COP 9 the passage of the revision of Resolution Conference 2.11 (Revised at COP 9) was to prevent the very USF&WS administration of CITES elephant trophy hunting import permitting practices that are being repeated in 2002, elephant permit denials from Cameroon, which are on Appendix I but which have a CITES trophy hunting quota. The revision completely deleted the clause that had stated importing Parties could make a biological enhancement review and instead replaced it with the presumption that the biological non-detriment determination made by the export country should be accepted at face value" (Jackson, 2002).

"Thus the US Government uses CITES linked to the ESA as a means of intervening in the sovereign affairs of another nation, without proving that its actions are encouraging conservation. Their actions certainly are keeping countries like Cameroon from valorizing elephant as a sustainable resource, and in the much needed currency for the game department to operate and for

community development. The USFWS actions infringe upon the sovereignty of these countries, and take a patronizing attitude that they are incapable of managing and controlling the sustainable off take of their resources" (Jackson, 2002).

Species impacted by the "enhancement" process include the elephant in Cameroon and Mozambique, the cheetah and black-faced impala in Namibia, the black rhino in Namibia and South Africa, and the leopard in West, Central and North Africa (Jackson, 2006/11/14).

Enhancement Under the ESA as an Impediment to Conservation Of Cameroon's Elephant

The following case study on Cameroon's elephant shows how the USFWS changes the goal posts for enhancement, so that Cameroon can never meet their definition and thus can never export trophy hunted elephants to the USA.

Cameroon has an estimated elephant population of between 65,000 +/- 5,000 elephant, and of this 30,000 +/- 5,000 in the southeastern forests (Koulagna, 2002), depending on which expert one talks to. Tchamba, Barnes & Ndiang, 1997 predicted 27,619 country-wide with 24,899 in the entire forest zone. Forest elephants are difficult to count so complicated dung counting models have been developed with high standard errors. Southeastern Cameroon forests have among the highest concentration of elephants in Africa, varying from 0.8-1.5 individuals/km² (Usongo, 2002). Cameroon has a CITES hunting quota of 80 elephants of which about 40 are taken per year (MINEF, 2001).

The majority of the trophy hunted elephants come from Southeastern Cameroon. The off-take of 20 forest elephants in the southeast, even with a conservative estimate of 25,000 (Koulagna, 2000) elephants in the forest area of the southeast,

is 0.08% of the population.³³⁸ This must be considered insignificant with regards to potential negative impacts on the population and yet could generate significant income for elephant conservation and conservation in general.

The European Union (EU) respects Cameroon's CITES quota for elephants (Jackson, 2002) and its efforts as a leader in West African conservation, allowing trophy hunted elephant from Cameroon to be imported into EU member states.

However, the USFWS is not allowing trophy hunted elephant parts (e.g., tusks, ears, feet, tail, skin) into the USA, since Cameroon cannot show "enhancement" of the species. Using "enhancement", the USFWS keeps moving the "goal post", making it difficult for Cameroon to fulfill its continually changing but vague requirements for "enhancement" of its elephant populations. Some of the reasons given for the denial of these permits are contrary to CITES. Specifically, the requirements that are ultra virus (in excess of legal power) are the following (Jackson, 2002):

- (1) The criteria that poaching be controlled;
- (2) The criteria requiring better elephant population estimates, particularly in a heavily forested country;
- (3) The DSA/OSA³³⁹ requirement of proof of "enhancement" to make a CITES non-detriment import determination;
- (4) The DSA/OSAs disregard of Cameroon's biological non-detriment export determination; and
- (5) The DMA/OMA and DSA/OSA making their own duplicative biological determination of the findings intended to be made by the

³³⁸ Koulagna (2000) estimated 30,000 +/- 5,000 for Southeastern Cameroon

³³⁹ The U.S. Fish and Wildlife Service now designates its scientific authority as the Division of Scientific Authority (DSA) and management authority as Division of Management Authority (DMA).

exporting country instead of the complimentary "purpose of the import".

Since 1994, Cameroon has taken all the possible steps one could expect, and is seen as one of the leaders in conservation in Africa. Among others, these steps include:

1. 1994: The Forestry and Wildlife Law came into existence, which ensured that by 2002, 15% of the territory was in protected areas;
2. 1995: The Maroua Elephant Workshop was held;
3. The SCI MINEF (*Ministere de la Environment et Forets*, Ministry of Environment and Forests, Cameroon) elephant compact was established in which each hunter contributes US\$ 500 into an elephant conservation fund;
4. 1997: The second elephant workshop was held at the Mbalmayo Convent on the outskirts of Yaoundé;
5. Sept. 1998: The Cameroon Elephant Management Plan was officially adopted;
6. May 1999: The "Yaoundé Declaration" was adopted in which heads of state signed an agreement in Yaoundé over protection of the Congo Basin – Congo, Cameroon, the CAR, the DRC, Gabon, Equatorial Guinea and Chad to protect tropical forests in the region;
7. The prime minister's office created an anti-poaching committee;
8. 1999: Forest hunting blocks were geographically delineated to permit better management similar to already existing savanna hunting blocks;
9. 1999: MINEF began trapping the military, Justice Department and local authorities involved in ivory poaching;
10. 2000: The first income from sport hunting revenues (1999 season) was distributed to the state, local government and local communities from

block fees based on area, continuing each season thereafter (10% to villages, 40 % to communes and 50% to government plus trophy fees). It is unclear how successful this has been in getting benefits down to village and commune level (see Chapter 11, Section 11.11.6.7, Revenue sharing from safari hunting);

11. Jan 2000: Due to conservation actions taken by Cameroon, the European Union (EU) lifted its ban on the importation of sport hunted elephant trophies to Europe;
12. Southeastern Cameroon Elephant Implementation Plan Workshop, Yokadouma;
13. May 2000: MINEF attended the inaugural Bushmeat Task Force meeting in Washington, D.C.;
14. December 2000: The Lake Lobéké/Dzanga-Sangha/Nouabalé-Ndoki *Tri-National De La Sangha* National Park was created;
15. 2001: Cameroon appointed not only a “national elephant officer” but also an “anti-poaching officer” and a “bushmeat trade officer” to act as focal points in these key ongoing processes;
16. 2001: Ivory stockpiling and inventorying by MINEF was done using the Pierre Guerrini hunt donation to SCI;
17. 2001: The trophy quality monitoring program began in Southeastern Cameroon, linked to a WWF wildlife monitoring program;
18. Jan, 2001: A meeting took place between the wildlife directors of Cameroon, Equatorial Guinea, Chad and Gabon along with representatives of the collaborating organizations: WWF, IUCN (represented by its Regional Office for Central Africa), IUCN/SSC’s African Elephant Specialist Group (AfESG), WCS and MIKE to discuss the creation of a Central Africa Elephant Strategy (CAES);
19. 2001: The Project Noah Scholarship was set up to send one student from the savanna and one student from the forest area to the Tshwane

University of Technology, South Africa, to study for a diploma in nature conservation. The recipients are selected from rural communities where hunting takes place. By 2006, one student will be studying for his B-Tech and one for a master's degree, both returning in 2007 to begin developing a model integrating communities into the management of hunting areas;

- 20.** 2002: Douala housed the regional TRAFFIC office;
- 21.** 2002: Yaoundé housed the regional bushmeat task force office;
- 22.** 2002: The Organization for the Conservation of African Wildlife (OCFSA) moved its headquarters from Khartoum to Yaoundé following the need expressed by the Central African heads of state during the Yaoundé Summit of March 1999; and
- 23.** 2003: Two MINEF staff began their masters/doctorates to institutionalize wildlife monitoring in safari hunting areas as a means of setting quotas and making other management decisions, Shikar Safari Club scholarship.

Denis Koulagna Koutou (2002), director of Wildlife and Protected Areas for Cameroon sent John Jackson of Conservation Force the following email laying out the progress being made, and the frustrations about how they were being treated by the U.S. Fish and Wildlife Service, the subject being "elephant permits:"

"It is worth mentioning that in the wake of the summit of Heads of State of Central Africa on the Conservation of the Congo Basin Forest, only Cameroon developed an Emergency Action Plan and spearheaded the creation of Conference of Minister in Charge of Forestry in Central Africa (COMINFAC). Ivory and bushmeat markets, which were visible in the past, have been nearly stamped out in major cities. Emphasis should now be laid on airport and ports. In this regard, the African Elephant Conservation Act (AECA) of the United States) proposal would have been most helpful (USFWS refused to fund an antipoaching training program in Cameroon under the African Elephant Conservation Act). We

recently developed, with the World Bank Support, Forest/Environment Sectoral Program (FESP), which deals mainly with the wildlife and protected Areas Sub-Sector. A strategy for better management of wildlife and protected areas has been devised and is being adopted. In a bid to implement the FESP orientations 100 motorcycles, 20 double cabin Nissan were given to field services (conservators of protected areas) for a total cost of 750 millions CFA (US\$ 1,071,428). Coming to specific elephant-related problems, instead of the administrative battues that were organized in the times of Human/elephant conflict, the Ministry allocated 10 millions CFA (US\$ 15,000) to the provinces concerned to organize driving backs. As regards trophies, our stocks are well known and declared to CITES which will be invited for a marking operation. A fortified site is currently being built. The control of sport hunting is now well regulated and quotas are granted in agreement with international conservation organizations working in the areas (WWF for the North and The South East, CEDC³⁴⁰/University of Dschang/Leiden University for the Far North Province). Hunting zones are allocated through a transparent procedure, hunting activities are strictly monitored and agreements have been signed with private operators to better integrate the interests of local people and councils. Reforms are undertaken at the level of the Ministry to train and supervise village guards that would be recruited by the councils and communities. Back now on the regional grant, Cameroon recently offered, not only offices, but also some 30 millions CFA (US\$ 42,900) as well for the launching activities of the Organization for the Conservation of African Wildlife (OCFS) whose headquarters were moved from Khartoum to Yaoundé. It should be noted that most conservation organizations (WWF, IUCN, MIKE/CITES Program, Bushmeat/CITES Program, etc.) have moved their headquarters to Yaoundé. In addition, Cameroon has been designated as West and Central Africa representative in CITES Standing Committee..." (Koulagna, 2002).

“...I must say that I am deeply disappointed by all the setbacks experienced by you and our country despite all our efforts” (Koulagna, 2002).

³⁴⁰Center For Environmental & Development Studies of Cameroon /Centre Des Etudes de L’Environnement et de Développement du Cameroun, Maroua, Cameroun

The USFWS refuses to allow legally hunted trophy elephant from Cameroon into the USA, despite having a CITES quota. Cameroon's elephant is on Appendix I of CITES (CITES, 2005b) and all African elephant are listed as "threatened" on the ESA (USFWS, 1999). The USFWS had also turned down a Cameroonian government anti-poaching proposal to control the illicit movement of bushmeat and ivory (MINEF/SCI, 2000). The reader can judge for himself whether Cameroon has done everything possible to undertake good conservation.

Money is finally being distributed to stakeholders by the Ministry of Environment and Forests (MINEF) from hunting block area fees and trophy fees (SCI Africa Office, 2001b). During the 1999/2000 season, the following income from hunting and collecting in the forest was distributed as follows (Mboh, 2000).

- CFA 9,809,811 (US\$ 15,092) went to the villages (percentage of trophy and hunting block fee);
- CFA 15,003,244 (US\$ 23,082) went to the communes (percentage of trophy and hunting block fee); and
- CFA 78,747,654 (US\$ 121,150) went to the state (percentage of trophy and hunting block fee, as well as hunting licenses, collecting permits, arms tax).

Savanna Hunting Areas (Benoué, Faro, Boubangida), Year 2000, Money From Hunting Concession Block Area Fee Determined By "X" CFA/Hectare as provided by MINEF was (SCI Africa Office, 2001b):

- CFA 60 million (US\$ 92,307) went to the villages (10%);
- CFA 240 million (US\$ 369,231) went to the communes (40%); and
- CFA 300 million (US\$ 461,539) went to the state, not counting other fees such as *taxe d'abattage* (trophy fee) and hunting license fees (50%)

Ideally, more money should be going to the villages, but it is a start. Is Cameroon perfect? No, but they are trying. There is a need for auditing of how the money above is spent to assure transparency and accountability and this information needs to be provided to stakeholder villages. There is a need to better integrate local communities into the management of these natural areas for multiple use (see Chapter 11, Section 11.11.6 Eco-Genocide in Southeastern Cameroon, the Forest People and the Dobi Dobi, More Parks and Protected Areas). Corruption is a major issue as all over the subcontinent. Regardless, stopping the beneficiation of elephant will not save the elephant.

The principal author was informed by Richard Ruggiero³⁴¹ of the USFWS in 2001 of factions within the Cameroon military trafficking elephant ivory out of Congo Brazzaville (SCI Africa Office, 2001c):

“Says the minister (of Environment, Congo) is in cahoots with the Cameroonian military and President Biya of Cameroon. A large area in Congo south of Oueso is being poached out of elephant, with the ivory being transported through SE Cameroon via Moloundu or Ngoila/Lomie (Dja) to Douala via military convoy. The military uses this money to get rich and provide themselves with operational fuel for the army to function. Mr. Ruggiero showed me an email from Derek Westfall in US Embassy, Cameroon discussing this issue. Mr. Ruggiero explained that Denis (Koulagna) knows of this, but if he tries to stop it, he is out. Denis is very frustrated and he feels SCI and USFWS must back him up and support him. Mr. Ruggiero felt like Denis was the ‘BEST’ he has seen in a long time in Central Africa; a man with a vision” (see Section 10.3.3, CITES, Drives Ivory Market Underground).

In addition, in 2007, concern is being raised that the forest elephant is being heavily poached; valued at an average per elephant of US\$ 180 for ivory and US\$

³⁴¹ Richard Ruggiero, U.S. Fish and Wildlife Service (USFWS), 4401, N. Fairfax Drive, Rm. 420c, Arlington, Virginia 22203

6,000 for about 455 kg (1000 lb) meat (Tomlinson, 2007). Granted this does not look good, but on the other hand does it make sense to stop conservation activities linked to wildlife and elephant within Cameroon. The goal must be to try and make these programs stronger and more viable, for instance empowering the Baka Pygmies to become the “guardians of the forest” and to stop outsiders coming into their areas (see Chapter 11, Section 11.11.6.12, Let the Pygmies be the guardians of the forest).

It is believed that, among other problems, the USFWS policies towards wildlife in recent times stem from the infiltration of the service by animal rights groups under the William (Bill) Jefferson Clinton Administration. For instance, Sue Lieberman of the Humane Society of the United States (HSUS) (Bonner, 1993) was given a high level position within the service. It is believed that she opened the door for many more animal rights representatives. Even though she has since been removed³⁴² by the Bush Administration, many lower profile individuals representing animal rights philosophies are believed to still reside within the USFWS. If they do not directly influence policy, they find ways of stopping appropriate actions such as the refusal to fund AECA grants requested by Cameroon since 1995, including the Southeastern Cameroon Elephant Workshop and anti-poaching training.

10.7.2.2 Enhancement as a requirement. Why it was inappropriate in 1993 and still is so in 2002

The following are comments to the USFWS by world-class experts³⁴³ with African experience on proposed “enhancement” guidelines by the USFWS back

³⁴² Currently: Dr Susan Lieberman, with WWF-UK as Director of WWF Species program on +447769740311, email: sieberman@wwf.org.uk (see <http://www.wwf.dk/4d22774>).

³⁴³ Graham Child, Retired Director of National Parks and Wildlife Management, Zimbabwe, Advisor to the Botswana Government and Head of Wisdom Foundation; G. Hemley, Director of TRAFFIC USA; Rowan Martin Former Deputy Director, National Parks and Wildlife

in 1993. They are as relevant today as they were then, as this issue resurfaces on how the USFWS and maybe the EU interpret CITES Appendix I and possibly Appendix II hunting quotas for importation. Common themes coming from responses are:

- Adaptive management through careful monitoring of trophy hunted elephant tusk weights and hunter success is the one cost-effective means of assuring that trophy hunting of elephant is sustainable;
- If an error is made and trophy male elephant are over-harvested (0.5 to 1% of the elephant population with trophy tusks), this has economical but no biological implications on the particular elephant population;
- In the USA and Europe, total counts of game species are not cost-effective, nor are they required or used in making management decisions and in determining hunting off-take quotas, various harvest indices are employed (see Chapter 9, Section 9.7.7, Inappropriate or No Wildlife Monitoring to Assure Sustainability);
- Governments lack the finances, manpower and expertise to actively manage elephant herds and the ability to compensate rural communities for losses incurred from living with elephant and other wildlife;
- Providing economic benefits to impoverished rural communities to offset losses from living with elephants is the most important factor, as opposed to biological factors, which can help assure the

Management, Zimbabwe and one of the founders of the community based natural resources management program CAMPFIRE; Ian Parker Ex-Warden, Kenya and elephant researcher in Kenya and Uganda, author of many books including "The Ivory Crisis; D. Rottcher, Wildlife Veterinarian and Conservationist, Kenya Wildlife Service (KWS); H. Rumpf Permanent Secretary, Republic of Namibia, Ministry of Wildlife, Conservation and Tourism; Letter to USFWS from Department of National Parks and Wildlife (DNPW); Zimbabwe, Comments by Government of Tanzania.

survival of elephant and their habitat struggling to compete against an ever-increasing human population and their livestock;

- The biggest annual loss of elephant in Africa is from Problem Animal Control (PAC), in most cases even more so than poaching;
- Even in the case of declining elephant populations, trophy hunting can help reverse or slow this decline by providing the above-noted benefits to rural communities and governments to manage and conserve both the habitat and population; and
- The presence of safari hunting is a disincentive to poachers frequenting hunting blocks to illegally kill elephant. There is no evidence that sport hunting for elephants has ever been detrimental to a population.

It was viewed as neither impartial nor scientific in justification of “enhancement” by the USFWS, but more to appease the anti-hunting lobby. The presence of tourists in the Nairobi National Park and Amboseli Park is a disincentive to poachers, whereas with closure of hunting in Kenya in 1977, illegal hunting rose dramatically. No evidence of legal sport hunting in the last 40 years has been shown to be detrimental to elephant populations. Requiring enhancement by African countries in order to import trophy hunted elephant into the USA is analogous to saying to an innocent man,

“I know of no crime that you have committed or intend committing, but you must prove to me that you have committed no crime and do not intend doing so” (Rottcher, 1993).

Thus, there appears to be an assumption of inherent criminal or negative intent. The largest single source of elephant mortality in the 20th century was the lawful elephant reduction programs undertaken by governments to protect or make way

for agriculture (Rottcher, 1993). About 2,000 elephants/year are killed in Tanzania as problem animals in crop damage control (GOT, 1993).

Requiring Stable or Increasing Numbers of Elephant before Allowing in Hunted Trophies

Elephant populations outside of formal parks and reserves have little long-term prospect for survival, as a result of an erosion of their ranges by farmers. Thus, it is totally unrealistic to call for stable or increasing elephant populations (Rottcher, 1993).

“Is it inconceivable to use revenue from sport-hunting to a declining population to reverse the population trend through demonstrating financial value of elephants” (Rumpf, 1993)?

“East African elephant ranges have been contracting in the face of expanding humanity since 1925. Human increase correlates closely with decline of elephant range, which is the consequence of incompatibility between elephants and man’s agrarian land uses. Loss of range automatically produces declining elephant numbers. Only areas set aside in perpetuity for elephant – that is national parks, forest reserves and game reserves where agrarian land use is prohibited – have any prospect of long-range stability for elephants...Africa’s elephant range may still be more than 4 million km² (1.6 million mi²). Of this, less than 25% has any likelihood of long-term security as national park, forest or game reserve. Over the next century (21st) or so, it is reasonable to expect elephants to disappear over much of their range. In the face of this incontestable trend it is downright stupid to apply a blanket requirement that elephant numbers should be stable or increasing before they may be used by safari hunters. In most current huntable areas outside the permanent sanctuaries, the overwhelming trend will be unavoidably downward. This trend may be ameliorated and slowed if elephants have a value to the people usurping their ranges...” (Parker, 1993).

It is interesting to note in Kenya, there appears to be a direct relationship between the increase in human populations (+>3%/year) and the decrease in wildlife (large herbivores) (->3%/year), apparently from habitat loss (see Chapter 5, Section

5.7.1.3, Improperly planned land tenure and impacts on wildlife and conflicts between pastoralists and small-scale farmers, Amboseli and Maasai Mara, Kenya - Maasai Mara).

There are two effective measures for African elephant conservation: 1) adequate funding in state protected areas and 2) high economic value for elephant in the areas outside of them.

“Sport hunting of the African elephant confers a higher economic value than any other form of consumptive use, is not detrimental to the species and therefore an important and practical method of conservation...Rural communities in Zimbabwe presently (1993) derive US\$ 1 million from the sale of elephant for sport hunting. This enables them to offset the cost of maintaining elephant populations in settled areas and thus enhances survival; through the provision of elephant range beyond the boundaries of protected areas...sport hunting for trophy males also contains an element of self-regulation. The demand for elephant trophies is proportional to the density of males with trophy-sized tusks, and decreases in proportion to hunter success (high hunter success for big tusks – high demand, low success rate – low demand). Secondly the African elephant is sexually mature at about 14 years of age, and males only produce tusks of trophy quality (Zimbabwe average 26.2 kg/58.3 pounds) at the age of 25 or older. Even if sport hunters took all trophy males from a population, there would be a substantial proportion of sexually mature males to maintain the population. These would comprise males in the age range 14-25 years, and older males with naturally small tusks” (DNPW Zimbabwe, 1993).

An elephant population confined to a well protected area (e.g., safari hunting block) may be well protected, but declining since food becomes limiting. In such instances there tends to be a larger proportion of adult males and no reason why some of these males cannot be harvested by sport hunters.

“A limited trophy harvest of males is possible under almost any population condition except where the population has been subject to or has a recent history of high illegal off-take” (DNPW Zimbabwe, 1993).

Requiring Total Elephant Counts before Allowing in Hunted Trophies

Trying to get total elephant counts is difficult and expensive. Even in the USA, the world's wealthiest country, most wildlife populations are managed through measurement indices such as age of off-take and weight by individual, as opposed to detailed counts and precise knowledge of population sizes. If hunters or countries have to comply with all that the USFWS guidelines call for, then trophies from many African countries will not gain entrance into the USA and there will be nothing to counter the adoption of other land uses by rural communities which exterminate elephant more certainly than any other way (Rottcher, 1993) (see Chapter 9, Section 9.7.7, Inappropriate or No Wildlife Monitoring to Assure Sustainability).

Europe, Britain and parts of the USA – to name three regions – have managed wildlife populations successfully for centuries without management goals, describing the size and sex-age composition of populations. In deer management in the USA, off-takes are planned from age structure of the current year's hunting off-take, not detailed and accurate physical counts. The manner in which all farming and natural resources utilization proceeds is through practical trial and reaction to the results (adaptive management). Next year's use depends on this year's results. The developed states can produce no example of large-scale exactitude demanded of Africa by the Office of Scientific Authority (OSA) of the USFWS (e.g., total numbers of a game species) (Parker, 1993).

Enhancement for issuance of an import permit clearly exceeds the provisions of Article III of CITES, although it may be allowable under the ESA. Without

precise and operational definitions of “enhancement” and “clear evidence of enhancement”, it will be impossible for range countries to know what standards they must fulfill to satisfy the service (USFWS). Enhancement assumes that the elephant sport hunting program has been in place long enough to generate a significant body of “clear evidence” of enhancement. This would limit the ability of aspiring African range countries (e.g. Mozambique and Cameroon) to develop and implement elephant sport hunting programs by making them “off limits” to American hunters until they have already proven themselves. Such countries would be disadvantaged (Hemley, 1993).

“There are a number of potential situations where an African elephant population may be declining – due to directed management, habitat loss or poaching – but where sport hunting is not-detrimental or even enhancing the survival of the species...Wildlife populations are rarely managed to obtain some ‘optimal’ size and sex-age composition within political borders. Many elephant populations are at least partially migratory, and may cross international borders regularly and with impunity. Size and sex/age composition of herds will, therefore, change on a regular basis,...” (Hemley, 1993)

being dynamic and making it difficult to set static goals. Sophisticated field surveys even on a regular basis are beyond the capability of most wildlife management departments, even in the United States. Few wildlife management agencies anywhere in the world, including the USA, manage wildlife on the basis of “routine biological surveys” of both population composition and habitat condition. Most employ an adaptive management strategy, which monitors the age/sex composition of the harvest or an index of population trend (e.g., trophy quality, hunter success). The introduction of sport hunting in specific areas may provide the incentive for their long-term conservation (Hemley, 1993).

If the U.S. Guidelines are genuinely intended to enhance the survival of elephant in Africa they should forsake biological criteria and concentrate on socio-

economic limiting factors, including highest market value, not undervaluing it through over-regulation, and making sure people living with elephant receive sufficient returns as incentives to conserve the species. The over-hunting of the 0.5 to 1% of the elephant population with trophy tusks, if it were to occur, is of economic but not biological significance, as it does not affect reproduction adversely in wild populations and may enhance it by increasing the proportion of females per unit of population. At most, a “lower weight limit” should be placed on female and/or male tusks from sport hunting that may be imported. Experience shows that the only cost-effective way to manage unrestricted elephant populations is by applying the principles of “adaptive management” (Child, 1993).

“The issue which your proposal is trying to address is unfortunately bedeviled by a past history of actions under CITES, your Endangered Species Act (ESA), African Elephant Conservation Act (AECA), and various other proposed rules, adopted rules and guidelines. We would like to step back from this tangle of precedents and pose some fundamental questions, which we feel you should address...Let us consider...what approach should be adopted by a responsible conservancy agency in a country which is not a ‘range state’ for elephant – remembering that the sole tool which the agency has at its disposal is the power to determine whether or not it will permit the import of trophies from sport-hunted elephant:

1. It could prohibit the import of tusks which it thinks might not have been taken in such a way that the population from which the trophies originated was enhanced; or
2. It could admit all imports which bear the stamp of approval of the exporting company and look for other methods to assist in improving the management of the elephant” (Martin, 1993).

In the case of option #1, few African countries have the will or possess the means to introduce measures demanded by the proposed guidelines. Thus, option #1

would not have the desired effects in helping to conserve the elephant. If option #2 were taken, the USFWS OSA could monitor the magnitude and trend of trophy tusk quality (adaptive management) (Martin, 1993). Far more will be gained by option #2 (Martin, 1993), although in the opinion of the authors, monitoring should be the responsibility of the stakeholders from the exporting country with this information being made freely available to any importing country.

“If you really want to assist elephant conservation, then control of imports is not an appropriate method. It is rather like attempting to improve the standard of driving in Washington through the issuing of parking tickets...It is unlikely that an error in the import of a sport-hunting trophy by the Office of Scientific Authority (OSA) will be the deciding factor for the survival of any elephant population. Elephant will continue to decline in many countries as long as they are of no economic value – but they are not on the brink of extinction. There is time to put into place appropriate conservation measures through a sympathetic approach rather than one, which attempts to exert leverage. The underlying philosophy of the Endangered Species Act (ESA) – which is perpetuated in the proposed Guidelines – does not admit of an ‘adaptive management’ approach to these sorts of problems. Rather it seeks safeguards in advance arising from perfect predictions based on prior scientific study. It is not keeping pace with changes in methods of wildlife management and is unlikely to produce results” (Martin, 1993).

An “adaptive management” paper was attached to this response showing how tusk mass could serve as an important management tool and even be related to age and sex. Bull tusk trophy quality in Zimbabwe between 1987 and 1993 did not change significantly with yearly averages from a low of 18.66 kg/tusk (41 pounds) to a high of 20.34 kg/tusk (44.8 pounds) indicating that there had been no large change in bull trophy quality during this period (Craig & Gibson, 1993).

From an African perspective, one might call the current use of CITES and the ESA a form of eco-imperialism.

10.8 THERE'S AN AFRICAN LION JUST AROUND THE CORNER

Source: with permission from the artist, Paul Bosman, Wildlife Investment, Inc.,
<http://www.wildlifeart.net/books.html>

"Lion breed 'like rabbits' (over 20% per year) provided they have suitable habitats and protection. The Serengeti population is probably one of the best researched on the continent. It lost one third (33%) of its population due to an apparent mutation of the Canine Distemper Virus around 1994/95 (from 3,000 to under 2,000) and is back now to an all time high of around 3,800 in that ecosystem...The Kenyan listing is irresponsible. It recognizes the inadequacies of the recent censuses, yet it immediately turns around and cites them as if they were perfectly accurate...Tanzania has more lions than any other country in the world, and the majority of these animals live outside the national parks. If lion trophy hunting were stopped, they would have no economic value, and there would no longer be any incentive to conserve the lions. Opponents of trophy hunting have provided no alternative mechanism for funding the large-scale conservation efforts required to protect the species...I think that the situation in Kenya illustrates that lions would be viewed only as threats to people and livestock in the absence of trophy hunting. Lions in Amboseli National Park were exterminated by angry Maasai in the early 1990s, and 75% (three-fourths) of the lions in Nairobi Park were speared in the past year. Lions inflict serious damage to these

people's livelihoods, so why should they be tolerated outside the parks"? (Packer, *pers. comm.* In: Baldus, 2004).³⁴⁴
